**Manure.**—There is nothing like finely divided old hotbed manure, or in its absence good saturated stable manure. Long strawy material is worthless. The former would answer admirably for application at present sowing; the latter manure, not being decomposed is suited for autumn manuring.

**Planting.**—Plant early, especially those more tender varieties you have found difficult to mature. I wish to emphasise this maturation point, for I believe it the pivot on which success or failure turns. I prefer the end of February: a little protection against April or May frosts is easily managed. Where successions are necessary, the hardier and easier matured should be left last, though I know this is not the custom. Potting in the first instance would meet the case in most instances and obviate risk.

**Method.**—If necessary bury some manure beneath the corms; with a little clay, and a handful of clean river or road sand. The last is indispensable. A supply of liquid manure during the hot summer is very desirable.—W. J. M., *Clonmel*.

#### MARÉCHAL NIEL ROSE.

THERE has been rather a pleasing discussion in our Journal as to the best means of growing Maréchal Niel, and it may interest some of your readers to know that I have under my charge here one tree which I suspect is older than the one alluded to by Mr. Bardney at Hooton Hall. I have been often told that it is the largest Maréchal Niel in the north of England, and I have even heard that it is the oldest and largest in England; but as to the correctness of this I leave others to decide. The age of the tree here is eighteen years. It is budded on the "Victoria" stock, the length of which is 4½ feet. Circumference of stem 4 inches. The longest branch from the stock is 50 feet. The longest growth made last year was upwards of 20 feet. The total number of branches trained from the stock about twenty. The tree is planted against the back wall of a vinery 50 feet long, and is trained the whole length of the adjoining house, which is 30 feet long, thus making a total length of 80 feet. In addition to this length, 5 to 6 yards of some of the branches are trained back. The Rose is planted at the back of the flue, and the roots have passed under it probably to the Vine border outside. The aspect is due south. The first year I had charge I cut fifteen hundred blooms, last year eighteen hundred, and this year I am promised at least two thousand blooms. For many weeks last year from 140 to 150 were cut.

As to my treatment, I tie in all young wood; and at this time of the year I give weekly from four to five large buckets of liquid manure direct from the cow house. I regret to see that many of your correspondents find the Maréchal a delicate Rose to cultivate. My experience has taught me otherwise, but I hope to hear more about aged Maréchals in the country and less of delicate constitutions. This fine Rose tree may be inspected by visitors.—WALTER W. BROWN, *Foreman, New Gardens Nursery, Whitby*.

NOTWITHSTANDING all that has been said to the contrary it is a significant fact that exceeding few examples of Maréchal Niels of mature age are to be found in the country. The oldest and best I have heard of are on the Banksian stock, and they are some ten years old or thereabouts. I have long been interested in this fine Rose, and speak not without experience of its peculiarities. That it can be propagated with facility from cuttings, and will produce wonderful growths during the first and second year or so, is an undoubted fact, because it has been propagated in this way on an extensive scale in some of our best-known and largest nurseries; but it is equally true that the plants mostly die at an early age. I said to the propagator in one of these nurseries not long since, "How do you account for the mortality?" The reply was, "I can't tell you I'm sure, but we have many com-

plaints of the fine young plants we send out dying." These young plants, I may say, have been unusually fine and well grown, producing shoots 10 to 12 feet long the first season in 9-inch or 10-inch pots. I have had some of these plants myself, but all are dead now except two, and they are dwindling, having grown but little since they were planted in cool structures and just protected from frost and allowed to come on naturally. There cannot be a doubt, I think, of the precarious constitution of this Rose, notwithstanding the few isolated examples among the thousands that are grown that one hears of from time to time. We have lately heard a good deal from one of your correspondents about the Hooton Hall five or six-year-old plant, which cannot be regarded as an old Rose as Roses go, for much-pruned standards twenty years old may be found, and much older wall Roses of various kinds. There is that about the history of the Hooton Hall Maréchal Niel also which creates misgivings as to its condition. We are told, page 188, that two shoots are now observed starting from the base of the plant, and these Mr. Hanagan thinks of cutting the whole of the old wood down to—the fine top that has produced the hundreds and thousands of blooms, and of which he has been so legitimately proud! Why, I would ask, cut such a fine tree down to two suckers if it be flourishing as we are told it is doing? It would be an almost barbarous action, and excusable only in an extreme emergency—to save the life of the plant for example. Mr. Hanagan has, it appears, repeated this cutting-down process from time to time with other plants of the same variety. As to the crop of flowers "exhausting the energies" of the "Maréchal" or any other Rose, that is an open question. That the fruit or seeds do exhaust a plant no one doubts, but it has yet to be proved that a crop of mere flowers has any debilitating effect whatever. It is just as reasonable to suppose that a Vine or Peach, &c., can be exhausted by being permitted to flower only without being allowed to bear fruit; but such does not happen. We should certainly expect a Vine or Peach, from which the flowers were removed annually as soon as they fairly expanded, to go on growing vigorously for an indefinite time, and if the Rose is an exception to the rule it is for those who maintain as much to explain why it is so.—J. S., *Yorkshire*.

#### WEEKS'S HYDRO-CALORIC COIL—A COMBINED MODE OF HEATING AND VENTILATING.

THIS system cannot be better described than in the words of the inventors of it, and their description with the accompanying illustrations will make the subject plain to our readers.

"In addition to warming the air of the hothouse, room, or apartment in which the apparatus stands, it at the same time brings in from the outside a constant stream of fresh warm air, and that, too, without creating the slightest draught.

"On reference to the illustrations it will be seen that the coil, which stands on a kind of wooden box, presents outwardly the appearance of an ordinary hot-water coil, having top and bottom iron chambers connected by vertical pipes. On examining the plan, fig. 51, and section, fig. 49, however, it will be seen that each of these vertical pipes, which are 2-inch, contains a smaller or 1-inch air-pipe running through its entire length—in fact, right through the coil, and having its open ends exposed at the top and bottom. At the top the air-pipe is continued about 1½ inch into the chamber B, the open top of which is covered by an ornamental iron grating C. The box or chamber A, is connected by a zinc tube or some other kind of channel with the external air. It also has flaps or doors, D D, for opening into the house or room.

"The effect of this very simple and ingenious arrangement is, that when the apparatus is in operation the heated external surface of the coil (or part seen), heats the air of the room in the ordinary way; but while this is going on, the air in the small inner pipe becomes rapidly hot and naturally rises quickly into the chamber B, and thence through the grating C into the house, drawing in its course a constant current of fresh air from the outside, which in its turn passes through the coil, becomes warm, and enters the room as before. The following is a table showing the amount of air this coil will bring in and the temperature.

Temperature of water in apparatus.	No. of cubic feet of fresh warm air drawn in per minute.	Temperature at which the air is admitted into the house.
120°	15	90°
128°	19½	98°
136°	20½	109°
142°	21½	114°
144°	22½	116°
148°	23	117°

"By means of the chamber B the air can be admitted dry or

moistened at pleasure. If dry air is desired, chamber B is left dry; if moist a small quantity of water is poured in, sufficient to come up nearly to the top of the air-pipe (see section); and this water, being in contact with the top of the hot-water coil, becomes warm and gives off a gentle moisture.

"This coil is invaluable for hothouses of all kinds, particularly

forcing houses and vineries, as it enables them to be thoroughly ventilated in the most inclement weather without opening lights and sashes, as is necessary under the ordinary arrangements, thus avoiding the danger and damage to the crops too often caused by cold draughts.

"It may also be used as a fumigator for destroying insects, &c.

Fig. 50.

By burning the substance with the fumes, of which the air is to be impregnated at the mouth of the air channel, the building may be rapidly and thoroughly charged with any odour that may be neces-

sary. In the same manner the plants may be fed with ammonia or other essence if desired.

"It can be fixed to any existing apparatus; in fact, an admirable

Fig. 51.

mode of increasing an apparatus of deficient power would be by inserting one or more of these coils as might be found necessary (see fig. 52). This could be done with very little trouble, and only slight alteration of the existing work.

"One of the chief merits of this invention is that there are no fans or machinery for forcing in air. It is self-acting, requires no valves and no attention; but so long as the circulation continues it must perform its work in an efficient manner.

"The utility of this coil is not confined to horticultural structures;

for, in the form of fig. 50 it is admirably adapted for schools, churches, hospitals, prisons, halls, staircases—in fact, all classes of buildings whether public or domestic. It supplies an urgent and long-felt want—viz., a simple and satisfactory method of introducing pure warm air into buildings without draughts. It is particularly valuable for hospitals and sick rooms, for (as before explained) it not only induces a constant change of air, but enables them to be thoroughly disinfected at pleasure.

"It may be mentioned that the doors or flaps marked D D, in

conjunction with another flap at the mouth of the air channel, enable the warmth to be got up very rapidly in a cold room—thus: The flap admitting the air from the outside is closed and the doors D D opened. The result is that the air of the apartment is drawn in at doors D D and passed through the coil, and this process goes on until the whole of the air in the apartment is warmed, when the flap at the mouth of the channel is again opened and the flap D D closed. Used in this manner the coil is at least 40 per cent. more powerful than an ordinary coil of the same size."

We have carefully inspected the working of this apparatus,

and can testify that its action was thoroughly satisfactory. The influx of warmed air as tested by the anemometer was even greater than represented by the above table, and when a little ammonia was poured in the box outside the house communicating with the coil, the fumes in a few moments pervaded the apartment. Many practical gardeners admit the value of ammonia in vineries and Cucumber houses, and obtain it by placing guano in the evaporating troughs, believing that it not only invigorates the Vines and plants but is an antidote against insects. By the use of this apparatus as much warm air, moist or dry, as is needed

Fig. 52.

can be admitted to a structure during the coldest days, and as much ammonia as is good for the crops can be provided, and a great deal more; but this of course is at the command of the cultivator, who must exercise his judgment in this matter.

#### CALANTHES AT DRUMLANRIG.

I READ with great pleasure the interesting article by "PARAGON" on "Drumlanrig in Winter," at page 165, in which reference was made to the Calanthes grown there. During the dull winter

months these beautiful flowers are not surpassed by any for utility or elegance, and hints or suggestions as to their improved culture are naturally received with satisfaction. The remarks of "PARAGON," however, appear to me somewhat complicated. He states that at the time of his visit (midwinter) the pseudobulbs were being potted and promised well for flowering. It would be interesting to know at what period of their growth Mr. Thomson pots his Calanthes. Does he pot them after the flower spikes appear? It is the custom of many to pot after the flowering is over and the plants have had a period of rest.

A good grower of *Calanthes*, Mr. J. Peers, Hillside, Wavertree, who exhibits them in great excellence, repots his plants when the young growths at the base of the pseudo-bulbs have pushed about half an inch, which is generally about the middle of March, and at that period of their growth it would be premature to judge of their flowering capabilities.—A. R. Cox, *Elm Hall, Wavertree*.

### THE GREAT FROST AND ROSES.

I HAD proposed to make some final remarks after pruning my standard Rose trees. After going over my two hundred trees I find, however, that, like the needy knife-grinder, "Story, there is none to tell, sir!" They are all equally now walking sticks with a round top and a feeble hope of not being quite killed. The heads were not protected, and I have not been able to prune back to sound wood with any one of them, except, perhaps, Fisher Holmes and Baron Bonstettin. I am glad to find the Hybrid Teas emerging better than the Teas. In spite of the general adverse feeling I still hold to these, and expect to see some achieve popularity—certainly the red Gloire de Dijon, Reine Marie Henriette. The more I inquire the more terrible I find the havoc amongst Roses in this neighbourhood. The firm of Ivery at Dorking have lost very largely; and that large grower Mr. H. Appleby, at the Boxhill Nurseries, estimates his losses at between four and five thousand, Teas having been killed in spite of careful straw protection. Both up and down the Mole I hear the same history. Thermometers carefully placed and watched have registered below zero. At Wonham Manor the head gardener of the Misses Marjoribanks, Mr. Good, gives 33° of frost on January 17th, and 34° on January 25th; and even this is exceeded at Burford Lodge, the residence of Sir Trevor Lawrence, where I understood 35° was registered on January 25th. I am particular in giving these, which coincide with my own observation, as I find happy people in warmer latitudes rather incredulous. That high authority Mr. Edward Mawley pronounces "that most minimum thermometers are very queer at very low temperatures." The common Laurels in these parts have suffered very severely, a day of hot sun at the time of the chief frost having apparently been especially injurious.—A. C.

AMONG all the catalogues, descriptions, and books on Roses, I never found Gloire de Dijon mentioned as anything but very hardy. This year, however, has proved fatal to five or six fine trees on Briars about four years old, and which were making splendid and well-ripened growth, three especially having nearly covered a south wall and porch. On cutting a bough that had fallen from the wall, to my surprise the pith was brown. Little by little I cut, gently at first, for I could not believe my favourite was killed; but in five minutes my tree was a heap of fragments, not a sound bit either green or old wood was left without the marks of frost, and so with the others. Strange to say other Teas, Niphetos for instance, has survived, but that was mulched above the union. This year the thermometer stood at 5°, last year at 7°, and the year before about the same. Can the 2° have made the difference, or was it the terrible winds?—GOOSEQUILL.

### HARDY FRUIT GARDEN.

THE prolonged cold weather has so far proved beneficial by retarding the expansion of the flower buds. The mild weather we are now experiencing is, however, causing them to swell freely. Apricots will be in flower shortly, and must be attended to in covering, or frost may destroy all hopes of a crop for this season. The buds of Peaches and Nectarines are also prominent, and dressing, nailing, or tying-in should be completed as soon as possible. Although these appear better than for the last few years the wood is not well ripened, and such should be cut back to the shorter-jointed and matured wood at the base of the shoots. The protective material must be prepared for covering the trees by the time the flowers show colour. Complete tying-in Apple and Pear trees trained as espalier or cordons, and cut back the leads of these and pyramids to about 12 inches to produce shoots for furnishing the trees. Figs that have been protected during the winter should now be uncovered. Pruning

is best deferred until the young fruits are visible. Excessive pruning must be avoided, cutting out only the stronger or unripened shoots as far as practicable during the summer, so as to insure a regular quantity of short-jointed well-ripened shoots. These, except when required to fill vacant space, may be allowed to grow from the wall to the extent of about 9 inches, and at the winter pruning it will only be desirable to moderately thin these to prevent overcrowding, and by judiciously stopping the points of those bearing fruit short-jointed fruitful wood will be secured.

### FRUIT HOUSES.

*Vines*.—The work in this department will require energy and method to keep pace with the requirements in disbudding, pinching, tying down, and thinning. Disbudding should be performed as soon as the most promising shoots can be determined, and only those should be left that can have full exposure to light and air. Care must be exercised in tying down the shoots, as when young they snap easily. As soon as the fruit is set cut away the bunches not necessary for the crop, removing those badly set, small, or badly placed. Commence thinning as soon as the berries are swelling. Keep up a good supply of moisture in all houses. Afford tepid liquid manure to the inside borders copiously, and sprinkle with guano water, so as to have the atmospheric moisture charged with ammonia. Where Grapes are colouring a rather dry atmosphere should be maintained, and a free circulation of warm air afforded, which is essential to good colour and finish. The rods of late Vines started at the beginning of the month should be syringed several times a day, and the border well damped every evening.

*Cherry House*.—Grubs are often troublesome on the foliage in its young state. They are of two kinds; one is enclosed in a case attached to the under side of the leaves, and must be carefully sought and destroyed, or it will soon give the leaves a scorched appearance, and will also perforate and destroy the fruit. The other will be found rolled up in the leaves, and is easily destroyed. Ventilation is of primary importance in the cultivation of the Cherry under glass, and must be attended to. Commence ventilating at 50°, at and above which allow a free circulation of air through the house, but regulating it according to circumstances. Artificial heat will be necessary to maintain 50° in the daytime, and at 40° to 45° at night, continuing former instructions in other respects for the present.

### PLANT HOUSES.

*Ferns*.—Pot at once any plants that need it, for if the young fronds are growing when it is done they will be checked. The best soil for delicate Ferns is good peat with about a sixth in equal proportions of sand and charcoal broken small, loam being added for those of stronger growth. If the fronds are required for cutting or the plants for decorative purposes, grow them in a light position and do not have the atmosphere very humid.

*Orchids*.—The growing season now commencing will necessitate a greater degree of moisture and heat. The evaporation troughs must be kept full of water, and the benches and floors have water poured over them morning and evening. In sunny weather plants that have commenced growth will be benefited by a light syringing in the afternoon. Plants on blocks will require frequent syringing. The water employed for all purposes must be soft, clear, and tepid. Except on sunny days little ventilation will be needed. Shake out *Calanthe vestita* vars. and *C. Veitchii*; cut the old roots away, and repot in a compost of three parts fibrous peat, old cow dung and fibrous loam a part each, and a similar proportion of broken pots or charcoal. Drain the pots well, and keep the plants rather dry until they begin to root, after which good supplies of water are necessary. Supply *Sobralias* with weak liquid manure, also *Calanthe Masuca* and *C. veratrifolia*. *Cypripediums* and *Cymbidiums* may also have a little weak liquid manure. Repot *Anguloas* in good fibrous peat, filling the pots half full of crocks, and over those place a layer of sphagnum, and then peat and potsherds, keeping the pseudo-bulbs slightly raised above the top of the pot. The temperature for the East India house 65° at night, or a little higher in mild weather, 75° by day, rising 5° to 10° from sun heat; Mexican house 60° at night and 70° by day; and cool house 50° at night and 60° by day. *Disa grandiflora* when growing strongly will be the better if the pots are in saucers. If

larger pots are needed shift now, using lumps of peat with a little sphagnum and sand, affording good drainage.

**Forcing House.**—Many plants will be starting into growth naturally; nevertheless, a successional batch of such as *Dielytra*, *Deutzia gracilis*, *Prunus sinensis alba flore-plena*, *Viburnum Opulus*, *Kalmia latifolia*, *Rhododendrons*, not omitting *R. odoratum*; *Azaleas*, *pontica* being very sweet, English and Ghent varieties very beautiful, and *mollis* varieties finer still and forcing quickly. Lilacs must not be omitted, and Double Thorns with Sweet Briar are generally esteemed. Roses also must be grown in quantity. Pinks, Lily of the Valley, *Hoteia japonica*, and *Spiræa palmata* will need to be forwarded in gentle heat, a temperature of 50° artificially being sufficient, and 10° to 15° or more from sun heat. A few *Lilium auratum* and *L. longiflorum* also should be placed in heat, and they will be useful when flowers are not very plentiful. To succeed these and to precede those in the open ground a cool house should be devoted to a successional batch of *Liliums*, ventilating freely above 50°. Damp the plants early in the afternoon of bright days, and moisten available surfaces in the house before nightfall. Violets, though late from the prolonged cold, are coming in well from plants in frames, and should have ventilation freely above 40°, withdrawing the lights with the external temperature over 50°. Water them when necessary with weak liquid manure, and do not allow any deficiency of moisture at the roots, or the flowers will suffer.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

**Hardy Climbers.**—Climbers are seldom sufficiently closely pruned; or instead of thickets of growth with a minimum of bloom we should see a vigorous growth, which would be neater in appearance and give the greatest amount of bloom. Roses, Clematises, Honeysuckles, *Cratæguses*, *Pyrus japonica*, *Jasminums*, and *Forsythias* are improved by being occasionally hard pruned, the young growth or the laterals of this following invariably giving the most satisfactory results. Roses that are uninjured and thinly trained should have all lateral growth spurred-in to about two buds of the main branches, all spray closely cut out, strong leading shoots laid in where requisite, and the fastenings generally made good. *Maréchal Niel* blooms best on the young growth, and this should be laid in thinly, cutting out any not required and as much old growth as possible. Early-flowering Clematises to have the young growth thinned out only, and the late-flowering, such as *C. Jackmanii*, to be cut back freely to induce the formation of strong flowering shoots. The Japanese Honeysuckle should have the thickest growth cut away, the young growth that will follow to be neatly laid in. Spur-in all lateral growth to near the main branches. *Jasminum nudiflorum* and *Forsythia viridissima* may be freely pruned where necessary immediately after flowering, laying in a few leading shoots where required. The long growths of deciduous Magnolias and *Chimonanthus fragrans* to be spurred in, leaving any of the flowering heads of the former. Ivies may be cut closely in, or if getting too heavy may be cut down; the young growth following, and which is generally the prettiest, to be thinned out and nailed up where necessary. The neat-growing *Ampelopsis Veitchii* needs but little pruning, but the old Virginian Creeper requires to be cut over. The former is much the better variety. The lateral growth of *Wistaria sinensis* to be spurred-in to near the main stems, laying in young growth where space is to be covered.

The present is a good time to plant climbers. Where the border is very poor a little good fresh soil should be added, especially if previously occupied by plants. Climbers are usually distributed in pots, and can be more quickly established in them if the roots are carefully opened out, cutting off those bruised or in an unhealthy state prior to planting. Do not bury them deeply, neither go to the other extreme, or they may probably suffer from drought. If the soil be dry supply water freely in the course of a week, and mulch with short fresh manure before hot weather be anticipated.

**Pruning Roses.**—This operation should now be performed in almost all localities. Many standards have been killed by frost; those much injured may yet produce fresh growth near the union of bud with the stock providing they are cut hard back. The growth resulting, if it does not flower freely, may yet lay the foundation of a good head of bloom the following season. Vigorous growers with sound wood

should not be cut back very closely, and may be left 4 or 5 inches in length; weaker growth being cut to about the second bud, in each instance pruning to an outside bud. All sprays should be cut clean out, and straggling heads be cut into shape. It is these old straggling heads that are most injured by frost, rather closely pruned heads remaining more vigorous for years. Dwarf trained, and those on their own roots especially, are comparatively uninjured, and for the future will doubtless be more generally grown. They may be pruned similarly to the standards, or the strong young growths may be retained to a good length and pegged down, cutting out the old flowering growth to induce the formation of other strong growth for the next season. The pruning of the dwarfs should not be neglected, or they will soon be beyond control. The Roses should be pruned in a manner similar to the Hybrid Perpetuals, or the young growth retained and the old cut out where possible.

#### PLANT HOUSES AND FRAMES.

**Propagating Bedding Plants.**—Pots of autumn-struck cuttings or old plants and roots of Verbenas, Lobelias, Heliotropes, Petunias, Veronicas, Ageratums, Abutilons, Dahlias, and Salvias, ought now to be placed in a gentle heat—a mild hotbed being suitable—in order to induce them to furnish cuttings freely. Any of these will strike readily in the aforesaid hotbed, providing a little ventilation be allowed should there be much steam in the bed. This is especially necessary this season owing to the excessively wet state of the heating material. The cuttings will also strike freely in boxes or pots covered with squares of glass, and placed on a staging near to hot-water pipes or flue in a forcing house. Both boxes and pots should be of sufficient depth to admit of a layer of crocks covered with a little rough material, 2 to 3 inches of fine sandy soil with a thin layer of sand on the surface, and a good depth for the cuttings so that these may just clear the glass; the latter to be kept on closely till the cuttings are struck. The tops and side shoots are the best; cutting the former clean across close to the third or fourth joint, and the latter with a heel or small piece of the old wood attached, trimming off the lowest pair of leaves in both instances. Insert the cuttings firmly and rather thinly up to the lowest leaves, and water in with a fine-rose pot. Coleuses, Iresines, and *Alternantheras* may be struck similarly to the preceding. The tops of bedding Pelargoniums when made into cuttings should be dibbled in round the sides of 6 or 8-inch pots, draining well and using light gritty soil. They strike best in a dry heat, and should not be watered till it is seen the soil is become rather dry. Glass should not be placed over these, as they are very apt to damp off. Cuttings of succulents, such as *Kleinia repens*, should be placed on a shelf to heal previous to being inserted, and but little water must be given until they are struck.

**Sowing Small Seeds.**—Lobelias, Pyrethrums, Petunias, and *Penstemons* ought now to be sown. Use light sandy soil, and either pans or boxes; drain these well, make the surface even, and water through a fine-rose pot a few hours previous to sowing. Distribute the seeds evenly, press them in with the bottom of a pot, and cover very lightly with sand or fine sandy soil. Closely cover with squares of glass, place on a gentle hotbed, and shade heavily till the seeds have germinated, when the glass should be tilted, and shading from bright sunshine only. Moistening from the bottom by partially immersing in a pail of warm water in preference to dashing water overhead. Tuberous-rooted Begonias, Gloxinias, *Torenia Fournierii*, and other choice fine-seeded plants may at this time be reared in the same manner as the foregoing. Fine peaty soil should be used if possible, otherwise leaf soil must be substituted.

#### THE STRAW HIVE.

I HAVE been honoured by a kind invitation to read a paper on "The Straw Skep and How to Make the Most of It" at the next quarterly meeting of the British Bee-keepers' Association, which will be held in London. The distance between Sale and London is too great for an old man somewhat shaky to travel on such an errand, and hence I did not accept the invitation, but I may

contribute a few observations on the subject to the *Journal of Horticulture*.

I admire the straw hive very much. Of all known hives it is the best looking, and of all hives used in Great Britain and Ireland it receives the greatest patronage. It is suitable for all persons, places, and seasons. I have used it for fifty years, and use it still with increasing confidence. The straw hive offers advantages which no wooden hive can for the comfort and safe keeping of bees in winter. If not too firmly sewed the straw hive affords a healthy ventilation, and permits the moisture to pass off through the walls uncondensed. Straw hives firmly sewn and thickly coated with paint, and with wooden hives of all kinds, the difficulty of removing the moisture of hives is very great in winter, and if allowed to remain it decays the combs outside the brood nest. Many schemes and inventions have been tried to clear the moisture from wooden hives in winter. The quilt has been tried, and perforations of their sides and crowns too. Wire gauge and cavity walls have been tried; last of all chaff has been used in the cavity walls, but whether any of these inventions and efforts have been uniformly successful I cannot say.

Straw hives in spring are certainly covered and kept warm, easily handled and examined. It is no small advantage to a working man to have hives which he can speedily turn up and examine internally. Anyone expert could turn up twenty straw hives and see all he requires inside in twenty minutes. Hives offering such facilities for examination enable bee-masters to ascertain how fast brood is spreading, how soon supers will be required or swarms expected. With other hives these things can be ascertained, but not, I think, with equal ease and speed.

At the time of swarming, and in natural swarming, the straw hive has no advantage whatever over other kinds of hives. At the season of swarming the heat of hives and the fanning of bees drive out by the doors all the superabundant moisture of hives. Hence there is no condensation of moisture in the height of summer. With straw hives the process of artificial swarming is simple and easy. Being easily handled they are turned up and placed on their crowns, empty hives placed over them, and swarms extracted from them by drumming—about five minutes is required to extract a swarm. This process of artificial swarming is a very near approach to Nature. The process generally adopted in the bar-frame school is a very unnatural one. About half the combs and half the bees are taken from a moveable-comb hive and placed in an empty one. It does not matter whether the queen goes with the colony or is left in the mother hives, as both hives have combs with brood in them, and therefore the bees without the queen can rear a queen for themselves. The removal of the combs with the bees is most hurtful to the mother hive and of questionable advantage to the swarm. This artificial method in swarming frame hives is not an argument against the moveable-comb hives, which could be swarmed as ours are by a method less artificial and without the removal of the combs. The difference of the two systems are now mentioned merely to show that moveable combs are of no advantage in either artificial or natural swarming.

In supering the straw hive has all the advantages and conveniences of other kinds of hives, for supers large and small and of all kinds of material—glass, wood, or straw—may be placed on it. Sectional supers may be placed on one to any extent. I am inclined to think that the Stewarton hive has a slight advantage in supering over both the straw and frame hives.

Cross sticks used in straw hives give them the advantage in some respects. Cross sticks give firmness and security to the combs, and thus prevent accidents and breakdowns in handling hives or in removing them from place to place. In summer there is great risk run in removing moveable-comb hives from one place to another, even when the bars are pretty full of combs, but straw hives with moderate care and fairly ventilated may be safely carried or sent by a common carrier from one end of the country to the other. They owe their safety to the support given to the combs by the cross sticks. Cross sticks in hives are advantageous in another respect. The bees in fastening their combs to them leave a small hole or byway at every stick or crossing, and thus four or five cross lanes or short cuts are made from side to side through the combs of every hive. For nadiring, eking, and enlarging the straw hive is probably unequalled, as every kind of enlargement can be securely fastened to it by nails.

Now let us come to the drawbacks of straw hives—viz., the inconvenience of fixity of combs and their unsuitability for the use of artificial comb foundations. Often have I admitted that moveable combs in hives are advantageous to clever bee-keepers, and that they can be well and profitably used under certain circumstances and at certain junctures in the management of bees. In a favourable year for honey gathering, or when almost

all hives are too heavy for keeping, the moveable-comb system appears to some advantage—I might say great advantage. Let us suppose that we have ten hives at the beginning of September weighing 80 lbs. each, all too heavy for stocks, and each containing twelve frames. How easy and how pleasant it would be to the bee-master to take six honey bars from each hive and leave the six central bars for the bees to winter in. Then it would be a stroke of good management, and no very difficult matter, to unite all the bees and combs of the ten hives in five of them; thus sixty bars of honeycomb—not all virgin comb—would be obtained, and five good stocks full of combs and well populated with bees. This would be capital practice, and nothing better can be said in favour of the moveable-comb system. Doubtlessly the moveable-comb hive offers other advantages, but all together would not outweigh the one now mentioned. Suppose that each of the five stock hives referred to contained 15 lbs. or 20 lbs. of honey for the bees to winter on. Suppose that all the honey was taken at the first and capitalised, putting £4 or £5 more money into the pocket of the bee-master, and all the bees put into empty hives—five in number—and fed with syrup into stocks at an expense of 20s. or 25s. This is my method of management with straw hives under such circumstances; and if any gentleman were to offer to sell me five stocks formed by the union of second-hand combs and five stocks—bar-frame stocks—formed by feeding with sugar syrup, I would much prefer the syrup stocks to the others, and give more money for them and expect greater results. This is a question of great importance in the management of bees.

One more objection to the straw hives I have to notice—viz., the difficulty of using and utilising comb foundations in them. This, doubtlessly, cannot be gainsaid. The straw hive as at present made offers very few and small facilities for using comb foundations, but if made with wooden crowns artificial foundations could be introduced and used in straw hives as easily and successfully as in bar-frame hives. I lately wrote on this subject showing how easily pieces of the foundations could be dropped into straw hives through slits in the crown boards and fastened on the outside. I think it would be quite as easy to introduce artificial foundations through the crowns of hives as it is to fasten them to frames. What is wanted is not the possibility of using them, but satisfactory evidence that their general use in hives would be remunerative. My opinion is not settled on this question, and I shall be pleased to find that artificial foundations are worth more in apiarian practice than all that has been said about them. I have frequently said that natural comb, pure and white, is much better for use in supering than artificial foundations, and I have as frequently hinted that such natural virgin empty combs may be produced at a cheap rate. This idea is worth a consideration. I wish some enterprising young apiarian would commence a factory for the production of natural virgin comb for use in supering. If such could be produced at a moderate price there would be a great demand for it.

Let us come again to notice the straw hive and the introduction of a swarm into it. By giving the bees 6 lbs. of sugar in syrup, costing 1s. 6d., in three or four feeds, they build combs down to the bottom stocks, the hive is nearly half filled with combs and brood in less than a week, and under sunny skies it will do more for a poor man than an Ayrshire cow will. What have I not seen done for many a family by four or six such hives in a garden. It is a useful, cheap, and profitable hive, and I know none better.—A. PETTIGREW.

#### THE HEATH BEE AND THE CAUCASIAN BEE.

[THE following paper was written for the Cologne bee meeting, but in consequence of the death of the author was not delivered, and has been published in the "Bienenzeitung," from which this translation has been made.—ALFRED NEIGHBOUR.]

GENTLEMEN.—I have no intention of drawing a comparison between the Heath bee and the Caucasian bee; I only wish to give you a short account of my experience as regards each of the two varieties of bees.

To begin with the Heath bee. The demand for Heath bees has been very much on the increase lately, though this is certainly not due to any special recommendation, and it no doubt proves that the good qualities of these bees are becoming more appreciated. It is a peculiarity of the Heath bees that they increase largely and give off many swarms, for which reason they are especially suitable for those bee-keepers who are anxious to increase their stocks, and therefore rejoice to see their bees swarm frequently. But the Heath bees do not only give off many swarms, they also collect large quantities of honey, as may be seen in the Lüneburg Heath district. In no part of Germany is the honey harvest so large as it is there, for while in other parts of the country pots suffice to hold the honey which the bees collect, the Lüneburg Heath bee-keepers are able to fill many casks. People are therefore disposed to look upon the Lüneburg Heath as an "El Dorado" where honey is always flowing, but this is by no means the

case. While in some districts a populous colony will collect 10 lbs. of honey in one day when pasture is plentiful, the outside maximum at Lüneburg is 48 per day. Nor does the Heath yield honey uninterruptedly all the time it is flowering. We are satisfied with an average of twelve fine days for utilising the Heath; if there should be any lightning while the Heath is flowering it frequently puts an end to the visits of bees. In many a year the honey harvest from the Heath is next to nothing. The Heath bee-masters know how to alter their method according to circumstances, and this is the principal cause of their harvesting such large quantities of honey. This affords me an opportunity of giving a few hints as to the management of Heath bees in case of their introduction into other districts. They are particularly suitable where the native bees do not swarm sufficiently. By simply intermixing the two races their hybrid offspring show somewhat more inclination to breed and to give off swarms. The bee-keepers' first and foremost endeavour should be to obtain swarms as early and as large in population as possible, and this he will be able to accomplish if those hives from which he intends the swarms to issue are fed simultaneously with a quarter to half pound of honey two to four times a week, commencing four to five weeks before the time of swarming, continuing the feeding until the first swarm has been given off. Should unfavourable weather set in about the time of swarming and continue, the first swarm might be driven off.

The first swarm will have sufficient population to form a separate colony, but the swarms that follow—and the size of which becomes smaller the greater the number that leave the parent hive—should be united so as to form colonies weighing at least 3 lbs. each. This is the more necessary in districts where there is no autumn pasture, but unfortunately this advice is very often not attended to. Every swarm, however small it may be, is frequently placed as a separate colony, and if it proves a failure people get dissatisfied and blame the Heath bees. When second swarms are put into wooden hives and can be assisted with a broodcomb or two from other hives they need not of course be made quite so large. When bees are found to make preparations for swarming, the drone comb both with and without brood and royal cells should be removed until the bees no longer show any inclination to swarm. If Heath bees are treated in this manner it will be found not only that they increase largely in population, but also that they are able to collect large quantities of honey.

I will now proceed to make a few remarks on the Caucasian bees. I must frankly confess that I had lately become somewhat prejudiced against the introduction of new races of bees. I always found them highly recommended, but on close examination they generally did not come up to my expectation. For the same reason I was prejudiced against the Caucasian bees, and was doubtful whether I had better procure some. While in this state of uncertainty I had a visit from Dr. Butlerow, Councillor of State of St. Petersburg, on his return from France, who requested me to give the Caucasian bee a trial, promising to send me two queens for this purpose from the Caucasus in the following spring. The two queens, each accompanied by a small colony and a supply of honeycomb, arrived here in excellent condition last spring, and were placed at the head of two populous stocks of German bees, the Caucasian bees being allowed to unite with the German. My first experience of the Caucasian bees was that they unite with the German bees without exhibiting the least signs of hostility towards each other. The attempt made a few years ago to unite Cyprian and German bees in the same way resulted in the attack by the Cyprian on the German bees, which in spite of all means of protecting the latter continued for several weeks until all the German population had been killed. My second experience was that they are very prolific and quite as fertile as the best colonies of Heath bees and the Italian bees.

The other qualities of the Caucasian bees could not be determined with accuracy until all the German bees had died off, leaving only Caucasians in the hive. With regard to their docility, which has been praised so much, I am able to state that they are very docile bees indeed. They do not sting when handled as bees generally are. I asked my son to irritate them, which he did, and I saw them buzzing about his face with the well-known angry sound indicating that they were ready to sting, but they did not sting him. After several repetitions one bee was at last induced to sting. We may therefore say, as a rule, the Caucasian bees do not sting, but if they are irritated they are capable of doing so. Because the Caucasian bees do not sting they have been supposed to be very phlegmatic bees, which would neither defend themselves against robbers nor collect much honey. But they are not phlegmatic; on the contrary, they are very quick and industrious. As soon as they make their appearance at the entrance of the hive they at once fly off to the fields, and on their return are in as great a hurry to enter the hive. On the outside the entrance is guarded by but few bees, but these are quite able to keep robbers away. Nor are the Caucasians, like other bees, to be seen in large numbers about the entrance of the hive in very hot weather; as they are very industrious it is only natural that they should collect a large quantity of honey. As far as my own experience goes I consider the Caucasian a very good race of bees which deserved to be introduced into Germany; but whether they will stand our winter well and prove satisfactory in every respect the future alone can show.

I will make one more remark. As everybody knows it is no easy

matter for the offspring of a new race of bees to be kept pure. In colonies of other bees, such as Italian hybrid bees are readily recognised by their colour, but this is not so easy in a stock of Caucasian bees. It is therefore to be feared that many stocks may be sold as Caucasian bees which are either hybrids or even entirely degenerated bees; purchasers ought therefore to be on their guard in this respect. —G. DATHE, *Egstrup*.

#### TRADE CATALOGUE RECEIVED.

James Carter & Co., High Holborn, London.—*Catalogue of Farm Seeds*.

**Campanula persicifolia alba** (W. S.).—This plant is quite hardy and thrives admirably in moderately rich garden soil, yielding a profusion of flowers that are extremely useful for cutting.

**The Black Corinth Grape** (H. M.).—This is the variety that produces the Currants of the grocers. It produces insignificant bunches and seedless berries. It requires the heat of a vinery. We do not know where you can procure this Vine, but if any of our readers can supply the information we will readily publish it.

**Gooseberry Bushes Broken with Snow** (J. S., *Cairnie*).—You cannot do better than place stakes to the injured bushes, and secure the branches to them with either strong tarred twine, nearly as thick as the stem of a pipe or the young shoots of willows. Some of the partly broken branches will unite if they are bound up with twine, but others that are much injured will not do so. If they are split near the ground the broken parts after being secured should be covered with soil.

**Double Cinerarias** (J. Butler).—You cannot expect many superior varieties from a packet of seed. The majority of your seedlings will probably be semi-double, while some will probably be single and worthless. Every plant should be grown, as if you pot only the best, throwing away the smaller, you will in all probability destroy just what you hope to obtain. You will find notes on double Cinerarias on page 211.

**Dahlias in Pots** (S. M.).—The dwarf-growing Pompon and Bouquet Dahlias are well adapted for pot culture for conservatory decoration late in the autumn. Rather late-struck cuttings are suitable, and the plants must have generous culture; they need, in fact, similar treatment to that usually accorded to Chrysanthemums, but even richer soil and more copious supplies of water. The pots must be plunged during the summer. We have seen healthy, handsome, and floriferous specimens in 10-inch pots, still larger examples in 12-inch pots, and small attractive plants, struck late, in pots 7 and 8 inches in diameter.

**Peat for Potting** (H. L. O.).—"The surface portion from an Irish bog" would not be the "correct thing." Fibrous peat as understood and used by gardeners is a sharp sandy soil mixed with the dead fibrous roots of heath; it is usually of a dark grey colour, and is very firm or compressed. Peat of the best description is thus constituted of 400 parts:—Fine silicious sand, 156; unaltered vegetable fibre, 2; decomposing vegetable matter, 110; silica (flint), 102; alumina (clay), 16; oxide of iron, 4; soluble vegetable and saline matter, 4; muriate of lime, 4; loss 2.

**The Seven Sisters Rose** (A. H.).—The Grevillea or Seven Sisters Rose is a variety of *Rosa multiflora*, a Japanese species introduced in 1804. The Seven Sisters produces its flowers in large clusters, opening purplish crimson gradually fading to pale rose. It is of vigorous growth, forming a handsome wall or pillar Rose, but is, Mr. Wm. Paul informs us, unfortunately tender.

**Select Pelargoniums** (J. W.).—If you require to stage six plants each of show and fancy varieties you must grow at least nine plants of each section, as you cannot rely on having every plant in exhibition form on a given day. The following are suitable for your purpose. *Show Varieties*.—Cicely, Artist, Purple Gem, Ruth, Prince Leopold, Virgin Queen, Charles Turner, Corsair, and Despot. *Fancy Varieties*.—Ann Page, Ellen Beck, East Lynn, Acme, Lady Mayoress, Mirella, Miss Godard, Mrs. Pope, and Phyllis.

**Good Phloxes** (P. Henshaw).—Twelve good early flowering varieties are Pearl, Mrs. Hunter, Cicerone, Mrs. Shanks, Vulcan, Marquis, Mrs. Morrison, Oberon, Mrs. McLellan, Mrs. Garrett, Mrs. Taylor, W. W. Platt. Good late-flowering varieties are Brilliant, Miss Wallace, Gladstone, David Thomson, Coccinea, Madame Bonneau, Madame Verrier, Princess of Wales, Splendour, Virgo Maria, Walter Ware, York-and-Laneaster. The time of the expansion of the varieties is influenced much by soils and seasons. As a rule if you state the number of plants you require and the purpose for which you need them to a florist you may depend on being well served, as it is evidently to the vendor's interest to give satisfaction to those who trust to his judgment. Plants, too, are usually obtained cheaper than when a purchaser makes his own selection.

**Wormcasts on Lawns** (H. S.).—Place a peck of quicklime in thirty gallons of water, stir well up, and allow it to stand for a few days until it is quite clear; then water the lawn thoroughly with the clear lime water. The worms will come to the surface, when they may be swept up and cleared away. This is an old and useful mode of eradication; but Messrs. Dick Radclyffe & Co. have stated in our columns that if 1 oz. of corrosive sublimate is dissolved in a little hot water and then mixed well in forty gallons of pump water, and applied to the lawn with an ordinary watering can in the evening after a shower, the worms will disappear, and the grass will not suffer any injury.

**Soil for Begonias** (C. D.).—The soil we recommended was the best suited for these plants; whether your "rich black ground" would answer instead of the loam it is impossible for us to say. We can only say that the plants are not very fastidious, and if you are not disposed to purchase a little loam all you can do is to try them in the compost at your command. Possibly they may succeed fairly well with judicious attention as regards watering.

**Heating Power of Saddle Boiler** (Rus.).—You do not give the width

of the boiler inside the arch. The usual sizes of saddle boilers are for 30 inches length, respectively, inside arch 12 inches by 12 inches, which will heat 350 feet of 4-inch piping, and 14 inches by 14 inches, heating 425 feet. These are the full heating power, and can only be obtained by hard firing, which entails great waste of fuel. One-third less piping than the maximum heating power should be allowed for fouling of the boiler surface with soot and economy in working.

**Jasminum Sambac Treatment** (*Idem*).—It requires a good light position in the stove, and where it can have fair ventilation. Being of semi-searant habit it should be trained on a trellis, or may be grown as a bush, affording support with stakes. It does well in fibrous loam, with a fourth of leaf soil and a sprinkling of sand, providing efficient drainage. The soil requires to be kept moist even when at rest, and when in free growth copious supplies of water, being careful not to make the soil sour by unnecessary applications. Sprinkling overhead in the afternoon during summer is highly beneficial. When at rest keep it moderately dry, but not so as to affect the foliage. Thin out the growth after the spring flowering, and train in young growth. Repot after the plant has been thinned and is starting into growth, affording weak liquid manure when the pots are filled with roots.

**Vine Roots Shortened** (*Dubious*).—The two-years-old Vines that have been "dug-up roughly" will no doubt grow very well if you shorten the rods in the same proportion. The "market grower" who sent you the Vines has probably not been in the habit of taking up Vines so carefully as gardeners do with the object of preserving "every bit of fibre." We have seen an extensive grower of Grapes for market deliberately chop off all the roots within 18 inches of the stems of young Vines when planting them, the canes having been previously shortened to about the same length. His object was to secure a great number of strong feeding roots, of which he calculated that each root severed would produce half a dozen or more "like porcupine's quills." The Vines so treated made splendid canes the first year, and eventually produced heavy crops of superior Grapes. If you adopt a similar practice, severing the roots smoothly, allowing no bruised portions, planting in free good soil, and shortening the rods considerably, your Vines will no doubt grow well; but you must allow them to start with a steady moderate temperature; forcing would be prejudicial.

**Sowing Annuals** (*Amateur*).—As you desire to have flowers as early as possible, and have no frame for advancing the plants, you may sow all the varieties of Nemophilas that you name at once, also Virginian Stocks, Veronica syriaca, Clarkias, Venus's Looking-glass, Collinsias, Larkspurs, Dwarf Convolvulus, and Saponarias. All these are sufficiently hardy to pass uninjured through any frosts that will occur now. The seed may be sown where the plants are intended to flower, choosing a fine day for the work. Where the ground works freely, some of the seeds being very small, must only be covered lightly with fine soil, as burying small seeds too deeply often prevents their germination. A very sharp look-out must be kept for slugs, which are greater enemies than frost, and often devour the young plants before the cultivator has seen them. As soon as the plants are growing freely they should be thinned out, as if permitted to be overcrowded in a young state they cannot be rendered satisfactory afterwards.

**Coal Ashes for Heavy Clay** (*E. J.*).—They are a capital dressing, improving the texture, rendering the soil more open and friable, and facilitating the percolation of water through it and admitting air. "Club" is not, unfortunately, due to ashes but to a grub, and mostly results from too frequent growth of the same or allied plants on the same ground.

**Repotting Vines** (*Reader*).—As we told you before, the system of repotting is only a safe one in the hands of experienced cultivators. So far as we can gather from your letters your experience in this branch of gardening is limited, and you had better rely on top-dressings and plunging the pots as you propose. Liquid manure will not be needed until the berries are swelling freely, and must then be given cautiously, commencing with it very weak. Your Vines will soon cease bleeding now they are starting into growth. As soon as you can perceive the bunches you may increase the temperature 5°, and as the flowering period approaches 5° more, at which temperature and a proper atmosphere the fruit will set freely.

**Solanum Capsicastrum Culture** (*T. W. Bushey*).—Seedling plants do not fruit nearly so freely the first year as plants raised from cuttings. All you can do is to pot off the seedlings as soon as they are large enough, growing them quite close to the glass in a warm frame or house until the pots are filled with roots; then shift them, keeping them in the same structure for a week, when they may be placed on a shelf in an intermediate house. In May they may be placed in a cool frame or pit, and towards the end of June be plunged in ashes in a sunny position out of doors. Until this time the shoots must be topped as needed to ensure a dwarf habit, and at all times short-jointed growth must be promoted. The plants must be potted firmly in good loam, especially when placed in their fruiting pots, which may be 5 or 6 inches in diameter. When the pots are filled with roots copious supplies of water are needed, and when the fruit commences swelling soot water is beneficial. Cuttings strike freely at the present time in sandy soil in heat, and make small fruitful plants in the autumn.

**Raising Helichrysums** (*Idem*).—If the seed is sown in heat too early the plants are liable to be drawn. Early in April is usually soon enough for sowing under glass, the plants to be treated the same as Stocks and Asters; or the seed may be sown in rich light soil in a warm position in the open ground towards the end of that month or the first week in May. The first-named plan is perhaps the best if it is properly carried out. Overcrowding the plants in the early stages of growth is the great evil to be avoided.

**Gloxinias** (*F. H.*).—You will find the address you require on page 169, August 28th, 1878, vol. xxxv. You are quite right in your supposition, and we are obliged to you for directing our attention to the omission in question.

**Selection of Ericas** (*Constant Reader*).—The varieties you mention are all useful and handsome; and as you have found them succeed by all means increase the number of plants either by propagation or purchase. The following twelve varieties will be found useful for successional flowering—Erica gracilis vars. autumnalis and vernalis, October to February; E. colorans, October to December; E. melanthera, February to May; E. Lambertiana rosea, December to spring; E. rubrocalyx, March to May; E. McNabiana superba, April and May; E. Cavendishii, May to August; E. ventricosa Bethwelliana, June and summer; E. tricolor splendida, June to September; E. Massoni major, June to August; E. princeps coccinea, August to October; E. Shannoni, August and September. To these add E. hyemalis, perhaps the most useful of all; E. Austriana, E. Marnockiana, E. Paxtoniana, E. Spenceriana, E. tricolor vars. rubra, speciosa, and Wilsoni, with E. vestita alba and rosea, and you will have a very good representative collection.

**Names of Fruits** (*Tillington Rectory*).—1, Golden Winter Pearmain; 2, Sam Young; 3, Winter Marigold; 4, Beauty of Kent; 5, Downton Pippin; 6, not known; 7, Dutch Mignonne.

**Names of Plants** (*G. S. Z.*).—1, Aralia Veitchii; 2, Vinea alba; 3, Euonymus latifolius variegatus; 4, Clerodendron Thomsonae. (*H. B.*).—1, Ceanothus puniceus; 2, Hepatica triloba; 3, Insufficiens; 4, Begonia manicata.

**The Stewarton and Straw Hives** (*G. W. V. M.*).—Mr. James Allen, carpenter, Stewarton, Ayrshire, makes Stewarton hives for sale. Probably Messrs. Neighbour, hive merchants, Regent's Street, London, may have them in stock. Mr. Samuel Yates, 16 and 18, Old Millgate, Manchester, sells all kinds of straw hives, specially the kind recommended in the book you have named.

**Removing Bees** (*James Dunder*).—The best time for removing bees from one garden to another, say a few hundred yards apart, is in the winter months, when bees do not venture far from home, hence the sooner the hive which you have sold to a neighbour of yours is placed in his garden the better. If it is now standing near other hives in your garden there will be some risk of the bees returning to the old place and entering the hive nearest to it. If there is no hive near it now it may be safely removed at once. If you want to avoid all risk send the hive to a distance of a mile or so, and let it remain there for three weeks, and then deliver it to the gentlemen.

**Stocks Destroyed by Mice** (*A. B. C.*).—If you examine the dead bees lying on the floorboards and about the hives you will find that their heads have been eaten off. Last year we sold a hive to a gentleman; the bees swarmed twice, and thus put him in possession of three good stocks. He covered them well up for winter, but omitted to contract their doors. On passing his garden this week we stepped in to examine his stocks and found all destroyed by mice. The bees were lying thick on the boards without heads. Three hives worth 30s. each were lost from want of a little attention. Your bees have been destroyed in the same way.

**Placing Stocks in New Hives** (*F. J.*).—Mr. Cheshire replies as follows to your query:—The risk of bees making a mistake in consequence of a change of colour in their hive depends on circumstances. If several buff hives stood in a row and one of those be suddenly exchanged for a green one, very many of the bees would probably enter the next hives, and queen-encasement would be likely to follow (see Mr. Raitt's article in last issue); but if the hive in question be not very near to others the change of colour would only cause a temporary hesitation on the part of the bees before alighting (and on this account genial weather should be chosen). Position is the great matter, even a difference in height of the alighting board, if of no more than 3 or 4 inches, giving them much perplexity. If we raise it they constantly fly beneath it, and are often much exhausted before they discover the entrance. All difficulty may be overcome by throwing a sack over the old hive two or three days before the change is made, and when the sack has been learnt as a landmark, putting the new hive in the old place and transferring the sack to it. The next day it can be altogether removed. We have found frames across the entrance useful to weak stocks, especially if the doorway be at the end and not the middle of the hive side. The bees keep their brood near the entrance and nestle in the corner, but this is only possible where the hives are excellent as non-conductors. The hives we are using give seven times as much protection as 1-inch pine, and with such, duly contracted, a quarter of a pound of bees may, we have found, be wintered in this country with scarcely a risk. In giving store in comb to help stocks in which the frames are across the entrance care must be taken not to place the new comb next the entrance, or robbing, successful or otherwise, is nearly certain. Strong stocks are rather hindered than helped by this arrangement of combs at any time—that is, that they can fly.

#### COVENT GARDEN MARKET.—MARCH 16.

WE have little or no remarks to make, our market being now at its lowest ebb both with supply and demand. The prices of vegetables are the same as last week.

#### POULTRY AND PIGEON CHRONICLE.

#### THE MANURING AND IMPROVEMENT OF PASTURE AND PARKLANDS.

(Continued from page 201.)

IN reference to the general management of pastures both feeding and mowing must be considered. We will take the feeding first. It is found that rich and fertile pastures are best adapted for the fattening of oxen, either with or without the aid of extra food. Inferior grass land, however, especially low-lying meadows or other cold clay soils, will usually return most profit by feeding with dairy cows, or by grazing with young cattle intended for the dairy. Hilly pastures, however, are more suited to sheep, especially if the soil is thin and weak, like much of the chalky,

sandy, and limestone soils. The best pastures should never be fed too bare, because the stems and blades of grass and Clover have both the power of drawing some nourishment from the atmosphere by the absorption of ammonia supplied by the rain and summer air. On the other hand if early highly succulent grasses are allowed to become too bulky they will be coarse, and will dominate the finer herbage, such as the white and yellow Clovers; at the same time also much of the produce will be refused by the cattle, and left to prejudice the aftermath. The ordinary meadow land is best suited for the grazing of dairy cattle, and cannot well be fed too closely, but especially the irrigated meadows, as these throw up such a quick succession of grass that it requires a heavy stock to keep the food in condition.

To return to the feeding of rich pastures, it is a common practice to feed with sheep as well as bullocks, in the proportion of one or two sheep to one bullock. The long-woolled sheep should be selected as companions for the cattle, for they are of a quiet contented habit; but the downs and crossbreds are more of a roaming disposition, especially the two former breeds, and, treading the grass under foot they make it distasteful both for the bullocks and themselves. In the autumn, where grass has been fed off either by cattle or sheep, if any tufts are left they should be mown down with the scythe, especially where dairy cows are grazing, for the seed heads of the grass frequently produce ergot, which causes abortion. If, however, it is determined to feed down the rejected tufts of grass it may be done by horses and colts in the absence of the dairy stock, as both horses and cows always benefit by change instead of feeding together.

We now must approach the question of mowing grass land for hay, and before making our own practical remarks we will quote Mr. Lawes upon the subject. He states, "If however, instead of accumulating a capital of fertility in the soil, a good crop of hay were the object to be attained, then the rapidly acting nitrates would be the best and cheapest application; for to produce an immediate effect, whether it be to grow a crop of hay or to force on a crop of roots, artificial manures are to be preferred to all other substances; but if the object be to increase the permanent stock of fertility in the land, then it would appear that feeding with cotton cake or the use of purchased dung would meet this requirement at a lower cost." Strictly, in accordance with Mr. Lawes' statement we had an instance on a home farm a few years ago which we had in hand, consisting of 300 acres, half arable and half pasture. The land was in as low a state as possible, and naturally poor. The pasture grass was nearly all destroyed by close feeding in summer and winter. In consequence we determined to use only the artificial manures on the arable land; and the yard, stable, and purchased dung, with earthy compounds from roadsides and ditches, upon the pastures and parklands, sowing some renovating seeds. The result was that at the end of three years both arable and pasture land was so much improved that the letting value was greatly increased. No hay was cut from the pastures, the arable land being made to furnish all the hay and straw required for a stock, which was proportionably diminished in the winter months.

Mr. Lawes writes as follows upon the value and effect of certain manures and feeding stuffs:—"1, The manure from a ton of decorticated cotton cake consumed on the land would contain, I should estimate, the following quantities of the three most important ingredients of plant growth:—Nitrogen, 130 lbs.; phosphate of lime, 149 lbs.; potash, 70 lbs. 2, Of the farmyard manures it would be necessary to apply about 11 tons in order to supply the above quantity of nitrogen, while the amount of phosphate of lime and potash taken together would not differ much from that contained in the cotton cake; but in the dung the potash would be greatly in excess of the phosphate of lime, while in the manure from cotton cake the phosphate of lime would be in excess of the potash. 3, Of artificial manures it would take  $7\frac{1}{2}$  cwt. of nitrate of soda, 5 cwt. of superphosphate, and 5 cwt. of kainit salts to supply the amount of nitrogen, phosphoric acid, and potash contained in the manure from a ton of cotton cake. I have used cotton cake since its first importation. I do not propose on this occasion to take the estimate founded on experiments carried out at Rothamstead; I will merely assume that its value per pound cannot be less than that of the mixed dry food, consisting of hay, roots, and corn, of which it took from 12 to 13 lbs. to produce 1 lb. increase of live weight; this would be equal to an increase of 187 lbs. per ton, and valuing live weight at 5d. per pound we have £3 18s. to deduct from the price of the cotton cake, and leaving the cost of the manure as £3 12s. Cotton cake therefore, even at the low meat-producing standard here assigned, would thus supply the cheapest manure, and artificial manure the dearest." In the foregoing statement we have the cost and value of manures and residue of feeding stuffs compared in a plain and practical manner, and our

own experience will not enable us to take exception to it. Pastures, when continually mown for hay, require very different manuring to those which are constantly fed by stock; and it must here be noticed that a disregard of these distinctions has in numerous cases been the cause of great disappointment in the result arising from the use of bones for pasture land. Mr. Lawes says, "Now the amount of potash taken up in the animal body by grazing is exceedingly small, while the phosphate of lime so taken up is comparatively large. The effect of mowing a pasture, therefore, is to reduce the potash faster than the phosphate, while the effect of feeding a pasture is exactly the reverse; and this being the case it is evident that bones, which contain a large proportion of phosphates and but little or no potash, cannot be an efficacious manure for grass land which is mown for hay." This statement at once explains in the clearest manner why the application of bones has been so successful in Cheshire, because the far greatest portion of the strong land pastures in that county are fed by dairy cows, and therefore reducing the phosphate of lime in the soil; on the other hand the manuring with manures containing potash are of little avail, because the strong clay soils contain so much of it in their actual composition.

It has often been recommended that grass land should be mown and fed by stock alternately. As a rule, however, mowing for hay encourages the coarser grasses to the detriment and exclusion of the finer herbage, particularly that of white Clover and yellow Suckling. There ought to be a distinction between valuable grazing land on the richest alluvial soils and the cold damp meadows of ordinary value. In the latter case mowing may be called a necessity, because a good crop of hay is the most profitable produce. On the other hand, we must consider the advantage of grazing the most fertile pastures, which often feed and fatten an ox and one or two sheep per acre; whereas mowing for a crop of hay on such land, irrespective of risk in making, has a direct tendency to injure the best and choicest herbage. Again, in newly-formed grass land it is much better grazed if we wish to form an early and permanent turf; for, although we may manure with liberality, yet cutting the grass for hay is sure to weaken if not destroy the bottom grass so essential in forming a good pasture. To conclude, we must return to artificial manure for top-dressing grass land and Clovers, and we cannot omit to notice the value of gypsum, which is composed of a combination of lime, sulphuric acid, and water as follows:—32.56 per cent. of lime, 46.51 per cent. of dry sulphuric acid, 20.93 of water, total 100.00; so that in every 100 lbs. of gypsum there exists 46½ lbs. of dry sulphuric acid—equal to 56 lbs. of the strongest liquid acid that can be purchased, and putting this at the low rate of 4d. per pound it is an astounding fact that the same quantity of sulphuric acid that you have in 1 ton of gypsum would cost to purchase no less a sum than £21. It is considered that gypsum has but little effect when applied to crops growing on wet clays and chalky soils. It is, however, contended that to obtain the full effect at any time it should be used in the finest powdered state, and sown upon vegetation after rain, when it will adhere to the leaves and stems of plants.

#### WORK ON THE HOME FARM.

*Horse Labour.*—The true economy of this is not only obtained by good feeding and judicious management in the field, but also by the use of animals of not less than 16 or 16½ hands in height, with substance in proportion. Two such animals, if in full condition will be capable of turning a single furrow in nearly all fallow ploughing, except the heaviest clays, and also of drawing with ease the double furrow plough in all the summer ploughings where the land has been once moved either by the plough or scarifier, and when thus used no driver will be required at any time, which certainly constitutes economy worth the attention of the home farmer. The next matter of economy is the use of the steam cultivator on all lands which have been winter-ploughed, not only for the purpose of saving time, but also in order to ease the horses of some of the severest labour on the farm. We must next refer to the feeding of horses, for we advocate the use of a moderate quantity of roots with the corn and dry fodder, whether of hay or straw, and as the Turnips are for the most part decayed by the frost, it will be well to commence feeding with Mangolds. The roots may be given whole in the manger, but should be spread out on a barn floor or mow for ten or twelve days before use; this will make them more wholesome at this early period, as they would otherwise be to some extent unripe and watery. The quantity may be about 10 or 12 lbs. of roots per horse per day; and our reason for giving the roots whole, and just as they come from the store without cleaning, is because the horses will not eat them so fast as when cut or pulped. If, however, the roots are given pulped it should be in admixture with hay or straw chaff. The horse labour now to be done will be Barley and Oat sowing, and if malting Barley is required the earlier in March the seed is sown the better. After roots are fed off by sheep we prefer to sow dreges, as we obtain good horse corn from this mixture, and grow more in weight and measure than can be grown from Oats alone.

The sowing of Clovers and grass seeds may now be done immediately after the sowing of the corn. If, however, grass seeds for permanent pasture are to be sown in the corn, we advise the home farmer to think over this matter with great care before he undertakes to lay much land now in arable into permanent pasture. Although at the present time corn sells at a low price we are by no means sure that this will last long enough to make it preferable. We have written much lately upon the question of laying land into permanent pasture, and its manuring and after treatment, yet when considering the work and cropping of the home farm we should ask ourselves the question whether we may not obtain nearly all the advantage we can expect from feeding a larger quantity of grass land without converting it into permanent pasture. Let us consider seriously whether our object of obtaining more grazing land cannot be obtained by a course of cropping whereby the land, having been seeded with permanent grasses, including Clover and Saintfoin, may not with benefit be fed for two or three years, and then fall into rotation for the growing of corn, &c., as before. Before deciding upon a matter of so much consequence in the future, we will suppose that a large area of our arable land has been converted into permanent pasture, and times may occur again in which corn and pulse will be dear. Circumstances we can neither foresee or control may occasion this, such as bad crops in America and other States whence we receive our supplies of grain, or from wars which may interfere with commerce. If we, then, had our two or three-year-old leas to deal with as arable land we should be in a better position to avail ourselves of an altered state of corn prices than after having disposed of so much of our arable land by converting it into grass for a permanency.

**Hand Labour.**—Shepherds and cattle-men will now often require some assistance from other men on the farm, unless women are found as constant workers, as they always used to be, and may be now with advantage to the farmer, in connection with preparing roots for stock. The breeding flocks will this year lose the greens of the Swedes in many instances; and as these are always made use of in feeding the stock lambs, the substitute now must be trough food, and similar to that which we have always recommended for feeding lambs for the fat markets—namely, the lambs to run forward into a fold without any greens or anything but trough food, which should be Swedes as long as they will continue in feeding condition. Cut and pass them through Gardener's cutter twice, and then mix them with cake and corn both in meal, so that it may adhere to the cut roots. In this way the lambs are sure to do well, except when we commence feeding with Mangolds, which is dangerous food for lambs. For many years we suffered greatly by losses of our fattening wether lambs by stoppage of urine whilst eating Mangolds; but the ewe lambs do well. It is not, however, found that lambs in store condition will suffer to the same extent as fattening lambs. Now is the time to obtain a good supply of calves for suckling as veal, for on the cheese-making farms they will be disposed of at a moderate price. Hereford and Devon calves we like best for making veal. The Shorthorn calves will grow and make as much weight but not the quality. In a suckling dairy, which pays well where farmers are not situated with the full advantage for the sale of milk, Shorthorn cows may be kept and should calve early, being fed well upon roots and cake, so that their own calves may be sold about this time and then be ready to take the full number of purchased calves. As they will at such a time be cheap and plentiful, we put two to each cow for a time, and by feeding the calves with balls of cakemeal at first, and afterwards with cake, malt, or maize meal in troughs. This will carry them on for a long time, two to a cow whilst in full milk, and the calves will be of a capital quality both in fat and colour. The yearling and two-year-old heifers will now be depending much upon Mangold and straw or inferior hay. The home farmer will this year learn the full value of Mangold, as the Swedes are nearly all decayed; in fact, Mangold is like money, you can never have too much if you only know how to spend it.

#### VARIETIES.

**MR. PETTIGREW'S FUTURE ADDRESS.**—Owing to the great number of visitors and letters I receive from all parts of the country, it seems desirable that it should be widely known that I am about to leave Sale; that on and after the 24th of this month my address will be Peel Crescent, Bowdon, Cheshire. But my connection with the nursery at Sale will remain till the end of May, or till my plants are sold. It is my intention to go to Scotland for three months—June, July, and August—to seek health, and if I find it to return to Bowdon, and there establish an apiary for my own advantage and incidentally for the advantage of all bee-keepers. It will be a bee farm managed to the best of my ability. An account of it, including income and expenses, will be given annually to the public.—A. PETTIGREW.

**FISH AS FOOD FOR FOWLS.**—We have recently heard from a poultry fancier that he has for some time been giving refuse fish, such as the heads, &c., to his birds, and that he has found this effect

a great improvement in their laying. The fish scraps are boiled and then mixed with meal of some kind. If any of our readers have the opportunity of getting fish refuse cheaply it may be worth their while to give the matter a trial. Fish undoubtedly contains much that is necessary for egg-production, and we are assured that the taste of the eggs is in no way affected by the feeding.

**THE HOG TRADE IN AMERICA.**—The hog production of the country, now mostly confined to the corn-producing States of the west, is, says the *American Cultivator*, larger than ever before known in the history of the business; while the exports of hog product on a large scale show a gain over the corresponding time last year. Since the 1st of November, for instance, the movement of meats, including barrelled pork, has reached the enormous number of 260,000,000 lbs., or 50,000,000 lbs. more than the same period last year; and lard exports have reached 105,000,000 lbs., or 20,000,000 pounds more than last year, the aggregate product amounting to 365,000,000 lbs., against 300,000,000 lbs., equivalent to the product of about 360,000 hogs.

**MANAGEMENT OF FARM MACHINERY.**—All farmers now-a-days use more or less of machinery, and necessarily learn much of its working and management; but they learn for the most part only in the slow and dear school of experience. The elements of physics—of natural philosophy—should be part of the common school course in all rural districts, and time for the study could easily be gained by devoting less to useless extravagances—the impractical extensions of arithmetical puzzles and of algebra. As to the wearing away of bearings—causing uneven, jerky motion, hard for the horses and damaging to the machine—we can only advise the application of oil wherever there is friction, frequent in proportion to the rapidity of the movement, with all possible care to prevent sandy dust from entering to grind away the surfaces. Farm machinery is especially exposed to this source of injury, and it is for farmers themselves to invent or select and apply means of protection. The manufacturers' care ends when they have put a smoothly running effective machine into the farmer's field, and got the money for it. Their interest after that is naturally heaviest on the side of wear and tear. Every person venturing on the use of a machine, from an Apple-parer to a grain-binder, should study it so thoroughly as to be familiar with every part, and with the reasons for their particular shape, size, and adjustment. He will then know what to avoid while it works well, and what to do if it shows symptoms of disorder or ill-function.—(*New York Tribune*.)

**EXPERIMENTS IN POTATO GROWING.**—An important series of experiments were conducted last season by Mr. James A. Gordon of Arabella, Ross-shire, Scotland, with the view of ascertaining the disease-resisting power and the productive properties of the following varieties of Potatoes:—Champion, New Victoria, Suttons' Magnum Bonum, and Suttons' Reading Abbey. The land was as nearly as possible equally manured, and the yield was as follows:—

No. 1, Champion .....	13 tons 2 cwt. per acre.
No. 2, New Victoria .....	12 " 1 cwt. "
No. 3, Suttons' Magnum Bonum .....	9 " 2 cwt. "
No. 4, Suttons' Reading Abbey .....	4 " 13 cwt. "

All were planted in the end of March in drills 32 inches wide. No. 1 came away most vigorously, and had very large shaws, which, overlying Nos. 2 and 3 on either side, perhaps slightly reduced their yield. No. 3 had also rank stems and promised a large crop. In No. 2 there was less growth of shaw, and still less in No. 4, which never gave promise of a heavy yield. In No. 4 black spots were observed on the shaws about the middle of August, and by the end of that month they were nearly all black. Black spots were seen on No. 3 about the 24th of September; but, though the leaves became black, the stems remained green. Nos. 1 and 2 also showed a few small spots on the leaves about this time, but on the whole they retained their green hue very well till lifted on the 8th of October. In No. 1 a good deal of disease was found among the tubers. About 10 per cent. had spots on them, and about one-half would be marketable, the remainder being undersized or diseased. Of No. 2 about three-fourths were fit for the market, and only a trace was seen on this variety. The condition of the tubers in Nos. 3 and 4 was similar to that of No. 2. All were of good quality, Nos. 2 and 4 being the best when cooked, as well as the best shaped. No. 1 showed a slight black-

ness at the end. Of his New Victoria variety Mr. Gordon had forty acres, which yielded an average of over ten tons per acre.—(*Irish Farmers' Gazette*.)

## POULTRY AND PIGEONS

### THE COURTE PATTE.

It would be difficult to find a better illustration of the little regard which is paid in France to what we call "fancy points" than the fact that the two leading French poultry books give entirely different descriptions of the Courte Patte.

In *Le Poulailleur* M. Jacque classes the Courtes Pattes with the Bantams. He says that in many localities in Brittany, Sarthe, and Orne there are Courtes Pattes, but that the true breed, which was formerly common in Orne, and from which was derived the delicious and precocious fowls called *Poulets à la Reine* is almost lost. He claims, however, to have recovered it, and describes it as follows:—"The cock weighs about 3 lbs. 3 ozs., the hen about 2 lbs. 2 ozs.; both are so short in leg and low in carriage that they waddle like Ducks, and that their fluff lies on and trains along the ground in spite of all their efforts to raise themselves on their legs. The comb of the cock is double, and has a small crest behind it. The plumage is throughout a mixture of white and dense black, with the exception of the tail, which is bronze black; the sickles are long and ample, the feet are black.

"The hen is extremely like the cock, and her very long tail forms a strange contrast with her legs, which are so short as to be almost invisible.

"This species lays very well and sits admirably. It furnishes us with excellent little birds which come early to maturity, and which were in former times much esteemed, and destined for the tables of the rich in the spring season when most fowls are not very tender."

The above account differs very materially from that given by M. Lemoine in his poultry book. He says, "This bird is of medium size and of a very rustic type; its flesh is of good quality; it is a very good layer, and a good but not an early sitter; its plumage is uniformly black; it has white earlobes and long wattles; it stands very low on its feet, which are large and black. The cock has a large single comb, which is upright and serrated."

Here, then, we have the two leading French authorities upon poultry matters giving us widely divergent accounts of what each calls the Courte Patte breed. We presume that M. Jacque had seen birds of the colour he describes with double combs and small crests, but there is no doubt as to these points the description given by M. Lemoine is that accepted both in France and in this country. At the recent Paris Exhibition the breed was numerous represented, and it has of late been shown pretty frequently in the Variety classes at English shows. We have in our own yards had some little experience in the breed with birds which we imported a year ago and a few chickens bred from them.

One of the descriptions above given is inaccurate, and the other is very meagre, while the account given of the economic qualities hardly corresponds with our experience; we therefore propose to shortly describe the breed as we have seen it and found it. We took some pains at the Crystal Palace Show to ascertain more fully the views of M. Lemoine, whom we had the pleasure of meeting there, and we also especially noted and inquired into the points of the breed at the Paris Show.

First, then, as to size. Our birds weigh from  $4\frac{1}{2}$  lbs. to 3 lbs., and are by no means as large as the winning cock at Paris, which we should think would easily have scaled 6 lbs. This bird was, however, considerably larger than any other at the Show, so that we may fairly, we think, place the weights at about 5 lbs. for cocks and  $3\frac{1}{2}$  lbs. for hens. The shape and carriage are unique, and are, of course, materially affected by the short legs, from which the name is derived. In a good specimen one is struck equally with the extreme shortness of the legs and the great length of the body. In no other breed that we are acquainted with is the length of the body so great as compared with its depth, while the carriage is more like that of a Duck than a hen. The legs are so short that the ample plumage almost touches the ground, and the body is carried so horizontally that the breast is nearly as close to the ground as the fluff is. The breast is full and the back almost level, so that the bird has the appearance of being very solid. An upright carriage or any shortness of body is a great defect. The plumage is very ample and fairly close, and is black with brilliant green and purple metallic reflections. The

tail is large, and should be carried perpendicularly. The comb of the cock is single, of moderate size, evenly serrated, and erect; that of the hen droops to one side. The face and wattles are red. The earlobe should be white and smooth, but this point appears to be very difficult to attain, especially with the cocks. We have only seen one cock with an earlobe which could be called white, and we fear this will prove a great stumblingblock in the way of the breed here. At the Paris Show the one bird above referred to was first in the French Any other variety class; while second went to a bird good in other respects, but with very red earlobes. We trust the Judges here will show a similarly indulgent spirit in this respect, at least for a time. The feet, as also the legs, are black, and should be free from feathers. The feet look large in consequence of the legs being so short, but they are really rather small than otherwise. We regard feathers on the legs as a great defect. They indicate a cross with some feather-legged variety, and should be mercilessly repressed.

So much for appearances, now as to the qualities and habits of the breed. We find them moderately good layers of eggs, which are very large for the size of the birds, and are much like those of a Spanish hen. They are good sitters, and the shortness of their legs adapts them especially for rearing chickens of the more delicate varieties. The old birds seem hardy, but we have found the chickens difficult to rear, especially early in the season. We have not been able to spare any for the table, but from the peculiar conformation of their breasts, which are much flatter than those of any other variety, we consider them specially suitable for the table where great size is not desired. They develop with fair rapidity. When they have become acclimatised we expect better results from them both in regard to laying and rearing the chicks than we have yet attained.

We have seen it stated that they are non-flyers, and as easily kept in as Asiatics, but this is quite a mistake. Even the old birds will cross a 6-foot fence, while the youngsters are quite as light on the wing as any breed we are acquainted with. The cocks are very lively and have a jaunty air about them which is very attractive—they seem to be brimming over with conceit. We have not much tested their powers of bearing confinement, but think they will stand it fairly well.

We have no doubt that the breed is, as stated by M. Jacque, of very ancient origin. It has the merit of having very distinct characteristics which are well established, and there is a certain amount of quaint beauty in it which with its useful qualities should recommend it to English fanciers.

### THE MODERN DORKING.

THERE is a controversy which from time to time is waged among poultry fanciers. For some weeks it is briskly carried on in print, then it slumbers and dies a natural death; after a time it is revived and carried on with all its own animation, sometimes one might almost say aerimony. The great question is whether the modern Dorking is superior or inferior to the Dorking of thirty or forty years ago. I do not say "great question" ironically, for as the Dorking is *par excellence* the table fowl of England it is a question of some importance whether a bird which should grace every banquet is not kept up to a due standard of excellence. Though this breed has long been my *spécialité* in poultry I have never taken much part in these controversies, and so venture now to collect my ideas upon the subject, in the hope that, if not instructive to any fancier, they may at least be impartial. I am the more inclined to hope that they may so be from the fact that I do not find myself entirely in agreement with either the one or the other side. The exception to my silence has been when some three years ago I craved space in your columns, as well as in those of one of your contemporaries, for a few lines on the "modern Dorking." Unfortunately there are, or have been, now and then changes of fashion as to the desired characteristics of poultry. Just then at the Crystal Palace and other great shows nearly all the prizes had been given, and that by some of our best all-round judges, to Dorking cocks with immoderately long legs, presumably because they were heavy in hand. There was then a general outcry, in which I joined, from all the principal Dorking breeders against these awards. This expression of opinion had its desired effect, and since then there has been, as far as I have seen, a general return of favour to the older and more approved Dorking type.

The controversy at present seems rather to be, not over this or that type of Dorking as now generally exhibited, but between on the one side the really old fanciers who hardly exhibit at all now, and who maintain that they formerly possessed a race of Dorkings, now nearly extinct, but in all useful qualities superior to the present Dorking; and on the other side the admirers of the

modern Dorking, which they believe to be in some points an improved fowl, and if a good specimen be taken, in all ways equal to any Dorking ever produced. The difference of opinion seems reduceable to these heads—1st, The form and size of the breed; 2nd, The colour; 3rd, The feet; 4th, The ears. On some of them the difference is certainly merely one of the degree of weight to be given to certain merits and defects. I will, if I may, briefly give my humble opinion on each of them. I have not the advantage of the years of some of the great authorities on the subject, though I hope that a very careful observation of poultry from six years of age, specially the Dorkings in the old-fashioned farms of Middlesex and Surrey, may in some degree compensate for this disadvantage.

1, *Form and Size*.—There can, I think, be little doubt that in size the breed has appreciably advanced within the last twenty years. The records of the weights of the prize birds at Birmingham when they were judged chiefly by weight, and when consequently exhibitors fattened their show birds far more than they do at present, will prove this; but then, has this size been obtained at the loss of some form? I think, taking the Dorkings all round at one of our great shows, that it has. There are always to be found a number of leggy ungainly birds not suited to the table. I do not, however, see any necessary connection between this general increase of size and deterioration of form in some specimens. There are always birds to be found of great weight and size with the true Dorking shortness of leg and roundness of breast. The number of leggy birds still to be seen is, I fancy, due to the unfortunate favour shown to such, as I have said, a few years ago. Harm was done, too, by the saying of a once great breeder of Dorkings that a short-legged bird could never have a frame to carry much flesh. That idea is now quite exploded, and many of us—nothing daunted by being for two or three seasons beaten in the show pen by birds which we knew were, as Dorkings, inferior to our own—have stuck pertinaciously to the old form, and have been rewarded for it. Certainly I can never remember seeing more perfect Dorkings in form than many of the winners at the great shows of the past season. It is quite true, as I have said, that leggy bad birds were to be found, but seldom in the prize pen. Some breeders have not disposed of the strains which to the great regret of real Dorking fanciers won for a time, and will, I fear, find it difficult to do so without a general slaughter and a fresh start.

2, *Colour*.—Here I think harm has been done, and that almost entirely in the case of the Dark variety, by the arbitrary requirement that the hens should be of an almost uniform shade of rich brown with black neck hackle. Nothing is so fatal to the utility, as apart from the fancy beauty of a race, as the requirement that cocks and hens shall respectively have markings or colour not obtainable generally from the same parents. The colour which has of late been fashionable for Dark Dorking hens is one which frequently, at least in my opinion, produces many nearly black cockerels, and thereby shows that it has been obtained by some cross. I do not say that this is always so, for some years ago I obtained two pullets—not large, but models of Dorking shape, with perfectly white feet—descended from an old Dorking race; they were of the favourite dark brown colour, and yet never produced a too dark cockerel; indeed, when the son of one of them took the cockerel cup at the Crystal Palace the only fault found with him was the lightness of his hackle. What I disagree with is not admiration of this rich colour in the hens, but the exclusion of all other colours, even when combined with size and other excellence. There is a lighter type of hen, certainly not quite so handsome, in which the tips of the feathers are of a darker shade than the rest of them; sometimes this darker marking approaches lacing, sometimes spangling. I have almost invariably found this colour to accompany great size and white feet, and to go with handsome moderately dark plumage in the cocks; it was formerly often seen in the show pen, but of late has been somewhat tabooed by judges, and most unfortunately so I think. During last season I occasionally showed a very fine pullet of this type, but she never received more than a “very high commendation;” while one at least 1½ lb. lighter, but of the favourite brown hue, took the highest honours. In the case of the Silver-Grey variety there is some difference, for it is confessedly to some extent a breed of feather; however, I have usually found with it, contrary to one’s experience in many breeds, that the most approved form and colour go together.

3, *The Colour of Feet*.—Of course no one wishes or likes to see a dark foot on a Dorking; the question is, Is the prevalent inclination to darkness to be tolerated in very fine specimens, or must it be stamped out? Here, I think, the old fanciers have the best of the controversy. There has of late years certainly been a great increase of “sooty feet.” I was perfectly astonished when judging

not long ago at a great Scotch show to see the number of otherwise excellent birds failing in this point. What the cause of it is I do not pretend to decide; some say breeding for very dark plumage. I formerly thought this, but why, then, is it quite as bad in Silver-Greys as in Darks? I am inclined to attribute it to crosses, for I have observed it as specially bad in one strain of Silver-Greys which was long famous for very silvery cocks and pale-breasted hens, and which I am sure had Silver Duckwing blood in it. Dark marks are a great blemish on a leg supposed to be white both in the poultry yard and on the table. I have found them more prevalent in birds inclined to be leggy than in those of true Dorking form; for these reasons I think they ought to be vigorously excluded from the prize pen and the breeding yard alike. It is sometimes said that this is a merely fancy point. This argument falls to the ground if there can, as I believe there can, be shown to be some connection between purity of a race which has always been known as a most palatable one and whiteness of feet.

4, *Colour of Ears*.—For some years most Dark Dorkings had red ears, and little was said about the point. Of late some of the best specimens have shown some white in the deaf ear. Great objection has by some fanciers been raised to this as a proof of a cross with Minorcas or other white-eared breed. This I doubt, for I observe that white in ear generally goes with good Dorking form, and I can remember, too, that the old farmyard Dorking almost invariably had some white in ear; indeed, one of our ablest judges tells me that he remembers it being considered a point of purity, and Mr. Harrison Weir’s well-known illustration confirms this view. In my own yards I shall certainly not exclude a white-eared bird when otherwise good, nor do I see any reason for looking upon it in moderation as a drawback in a show pen.

Such roughly are my ideas upon the relative merits of the older and newer Dorkings. I give them for what they are worth and do not dogmatise, but shall be only too glad to hear and consider the opinions of others of your readers on the subject. Looking at the Dorking all round I fear we have lost something in plumpness and smallness of bone; on the other hand we have gained size and greater hardiness, and I believe that by the present careful selection carried on by several enthusiastic fanciers we are likely to combine the excellencies of the old and new birds. In one point my own experience is that we have gained and are gaining much—that is, “bumble feet” are much on the decrease. This I attribute to a requirement which some may call absurd and arbitrary—viz., that the fifth claw should be turned up and well separated from the fourth. There is, however, reason in it, and I well remember that when the two hind claws were frequently set close together or confused, or even had the abnormal addition of a third, inflammation and disease in the feet were far more common than I ever find them now.—O. E. CRESSWELL.

30th	W	Royal Botanic Society—First Spring Show.

## CULTURAL NOTES ON PRIMULA SINENSIS.

GARDENERS and amateurs have often told me that their *Primula* seed does not germinate freely, and more frequently than otherwise they blame the vendor for selling bad seed, when the sower is often in fault. We are all liable to overlook small matters; and as success depends in a great measure on such, a few notes upon *Primula* culture will be seasonable and useful.

If *Primulas* are required to flower in the winter, March and April are the best months to sow the seed; if wanted in bloom in March and April, sow in May and June. Whether sown in pots, pans, or boxes these should be well drained with broken potsherds, covering them with the rough siftings from the soil, filling-up with fine soil within an inch of the rim. Place the pans on a level surface, and give a good watering sufficient to moisten the whole of the soil; in about an hour the pans will be ready to receive the seed. This should be spread evenly over the surface, and covered lightly with fine soil. Do not give any water after the seed is sown, but cover the pans with a piece of paper; and if the soil is likely to become too dry before the seed has germinated, sprinkle some water on the paper occasionally. Dryness of the soil while the seed is germinating is, I believe, often the cause of failure. The pan can be placed in a warm vinery, or any other house or pit where the temperature is kept to about 55° or 60°. When the seedlings are appearing through the soil the paper should be removed and the pan placed in a light warm place and shaded from bright sun, never allowing the soil to become dry. As soon as the young plants have two or three leaves they should be pricked off about 2 inches apart into pans or boxes. I prefer this plan, as the plants make roots faster than when at first placed in small pots. The pans should be still kept in a rather warm position until the plants touch each other, when they should be potted into large 60-size pots. As the weather will be warmer by this time, a cold frame kept rather close at first will be the best place for them until the end of September, when they should be moved to a greenhouse or pit heated sufficiently to exclude frost. If allowed to remain in a cold frame a covering should be employed every night, as they will not be safe from frost after the time named. As soon as the small pots are full of roots the plants should be potted into 48 or 32-sized pots, and again shifted, if large specimens are required, into 24's. I do not recommend overpotting, as the plants will flower better and be less liable to damp off in pots of moderate size. Be careful in watering at all times, and never allow the plants to flag. Should flower spikes be produced before they are required, pinch them out

during the summer months, and be careful to shade from bright sunshine from 11 A.M. till 3 P.M., unless the frame is placed in a shady position.

A suitable soil for potting may be prepared by mixing together one-third of turfy loam and one-third each of well-decayed leaf soil and manure, with a portion of silver sand and a little charcoal or soot. Should there be one or two plants of a superior quality and distinct from the rest, these should be placed on a shelf for seed and be carefully fertilised. If green fly appear fumigate with tobacco or tobacco paper.

As the double varieties do not produce seed freely, these should be increased by cuttings; or a safer way is, after the plants have flowered to remove the lower leaves from each crown, pegging the growths down a little towards the edge of the pot, and filling up with a little fine sandy soil, covering the whole of the soil with sphagnum moss or cocoa-nut fibre refuse. Place the plants in a warm house or pit, and keep them well supplied with water. In about six weeks the layers will be rooted, and should be cut off below the new soil and be placed in small pots, still keeping them in a warm position until well established, when they can be removed to a cold frame and treated like the single varieties. The old Double White (*Alba plena*) is the most useful of these, but it should be kept in a warmer temperature than the other varieties during the winter. I do not recommend any particular varieties, either single or double, as almost every seedsman has his own strain, and, I think, can generally be depended on, although there are some handsome named varieties in commerce at the present time.—JAMES CHILD, *Garbrand Hall*.

## GARDENING AT LONGLEAT.

AN observant visitor to Longleat will at once perceive that what Mr. Taylor, the clever gardener in charge, considers worth growing at all is worth growing well. This applies to the garden generally, including more especially fruit, vegetables, and flowers. Only what have proved profitable and of exceptional merit are retained, and of no kind do we see a great variety. In this respect a valuable lesson is taught those who are constantly craving for variety, the said "variety" not infrequently including many sorts which, if not absolutely worthless, are at all events unprofitable, especially where the demand or the resources of the garden, as at Longleat, are exceptionally heavy. We do not go so far as to say Mr. Taylor's selections are infallible, as what may be found most serviceable and which succeeds admirably with him may either be uncalled for, or probably may not succeed in the next district even. What we wish to impress on our readers, private enthusiasts excepted, is the advisability of growing a limited number of varieties of known excellence in great numbers in preference to an equal number of plants in many varieties, some of which are of doubtful merit.

Perpetual-flowering Carnations are in great favour at Longleat. To meet the demand large numbers of healthy floriferous plants are grown which probably are unequalled in any private establishment in this country. The chief variety is the Belle Rose, and a bright "beautiful Rose" it undoubtedly is, and should be found in every establishment where buttonhole flowers are in request. A good white companion for the Belle Rose is Purity, though it is scarcely so vigorous and floriferous. Both are clove-scented, the latter strikingly so. A stock of Miss Jolliffe is being worked up, a variety probably the most easily

grown of any. It is very free-flowering, but scarcely so sweetly scented as the foregoing; colour pale flesh. *Souvenir de Malmaison* is also grown on account of the great size of the blooms it produces, and one or two other varieties are on trial. No old plants are retained, the cuttings for next season's batch now being propagated. These when rooted are gradually hardened-off, potted into 3-inch pots, placed in a cold frame, and in May or early in June are shifted into 10-inch pots, the size in which they flower, and are then placed outside. A gritty loamy soil is used, fine for the cuttings, and later on in a coarse state. They are never pinched back, and the central and principal side shoots are supported with stakes. They flower during the whole winter most freely in the temperature of an intermediate house, and should not be crowded.

Mr. Taylor's method of striking Carnations, Roses, Gardenias, Verbenas, Iresines, and many other kinds is worthy of notice, as being altogether different from that usually practised. Boxes about 24 inches long, 15 inches wide, and 5 inches and in some instances 7 inches deep, are employed. These are lightly drained, and about 2 inches of fine soil is used with a thin layer of sand on the surface. The cuttings are dibbled in thinly, watered, and closely covered with glass in three divisions. Strips of paper are pasted over the unions of the glass, and also round the edges of the glasses and boxes. The boxes are then placed over a gentle bottom heat, or along the paths near to the hot-water pipes of a forcing house, and the cuttings shaded when necessary with sheets of paper. The orthodox method with propagating frames and boxes is to take off the glasses and dry them every morning, but in Mr. Taylor's case the cuttings are hermetically sealed down, and are not broken open till it is seen they are rooted, when the glasses are removed and the cuttings gradually hardened, other boxes of cuttings taking their places. The plan is very rapid in effect, as the cuttings never flag from the time of insertion, and is particularly suited to the clean houses and plants. The cuttings do not touch the glasses, and are not liable to damp off.—VISITOR.

#### LECTURE ON THE TULIP.

On Tuesday, March 22nd, Mr. Shirley Hibberd gave a lecture on the Tulip in the conservatory of the Royal Horticultural Society. The lecture, which we publish in a slightly abridged form, was illustrated by many of the flowers that have acquired historical importance.

He said: The Tulip being the oldest and most important of the flowers that obtain the attention of florists, it may be anticipated that its history is not lacking in materials for our entertainment, but there are some points in that history that we may perhaps with advantage consider.

In searching through the old books we fail to find reason for classing the Tulip with the flowers of antiquity. Although ancient as a florists' flower, it is not ancient in any other sense. It must have been known to the Greek botanists, but they give us no certain clue to it in their writings, and we are left in doubt as to their recognition of it as distinct from the Lilies and the Narcissi. Certain old English writers find in the Tulip the *Satyrium* of Dioscorides. However, we must dismiss from our minds all our cherished notions of the possible importance of the Tulip as a garden flower antecedent to its discovery by Conrad Gesner in 1559, and then we begin the history of the flower with the history of a man to enhance the interest. Gesner of Zurich, born in 1516, was not only the first to make known the splendours of the Tulip, but he was also the first upon record who formed a museum of natural history, and the first botanist who distinguished the generic characters of plants, and thus prepared the way for grouping species in accordance with their more striking affinities. In this man we have a fine example of the glory that accumulates, slowly perhaps but surely, around the name of one who not only loves but labours in his vocation, and has for the chief hope of his life the completion of the tasks he has assigned himself. The catalogue of Gesner's books will surprise anyone familiar with the fewness of the facilities for bookmaking in his day—a day so different to our day, when books, and especially horticultural books, are made by the simple process of copying, and rendered obnoxious and harmful by the blunders of the copyists. Gesner records that he first saw the Tulip in the beginning of April, 1559, at Augsburg, in the garden of Councillor John Henry Herwart. In 1611 they first appeared in Provence in France, in the garden of the celebrated Peiresc. The Dutch obtained their first supply from Constantinople. The first that were planted in England came, according to Hakluyt, from Vienna, being obtained thence by Carolus Clusius. In some of the books Clusius is put before Gesner as the discoverer of the Tulip, but Beckmann very properly describes Clusius as having only collected and described the then-known species. Gesner travelled to obtain plants for his own botanic garden at Basil, and also subjects for the painters and engravers he maintained at his own expense; and it appears to me a peculiar and proper event that such a man should secure for the delight of northern Europe, and the florists of Holland and England, the flower which until then had been monopolised by the gardens of Constantinople.

It is a happy circumstance that the Tulip conforms to the law of Nature, for, like the sun and civilisation, it is first seen in the east,

and the west learns of it by a second edition. The Tulip must have been for centuries cultivated in the east somewhere or other, because, almost coeval with the first knowledge of it as a plant in western Europe, we find it represented by many varieties.

Turning to the literary representatives of the gardens of northern Europe, I find the first proper reference to the Tulip to be in the "*Historie of Plantes*" of the famous Rembert Dodoens, published in 1578. At page 213 of the large edition, and page 240 of the small edition which has no figures, we find the Tulip described as the *Tulpia* or *Lilionarcissus*, and thus we are compelled to confront the problem comprised in its name. What is to be understood by the term Tulip, or Tulipan, or *Tulpia*? In the case of the Hyacinth, Narcissus, and many other plants, a fiction of Ovid or any other poet delivers us from a difficulty, and enables us to give a reason, however ridiculous, for the name of the plant; but now, in the etymology of the Tulip, we seem to be completely undone. In Richardson's Dictionary occurs the definition "*Tulipan*, the Dalmatian Cap;" and Cotgrave is cited to justify the term "*tulipist*" as applied to lovers of Tulips, which we should allow in the present day without a scruple on the same ground that we allow "*rosarian*" as applied to a lover of Roses, and shall in due time, perhaps, have to allow for "*solanumist*," as applicable to a man who is mad about Potatoes. It is as clear as can be desired that Tulipan is the equivalent of turban, and that this flower takes its name from its resemblance to the head-dress of the east. Herein we have hints innumerable for the students of costume, and especially for those who design the dresses for the pantomimes of the present and near future. The Tulip is a turban, and there is an end of that part of the subject.

In Dodoens there are two classes of Tulips described, which are distinguished as large and small, and I think it will puzzle the botanists to distinguish them clearly according to modern nomenclature. It is sufficient to say that they are described as of many colours, and as differing in size only. A rude guess would make them representatives of our present early and late sections; the tall sort being *Tulpia Gesneriana*, the reputed parent of the late Tulips, the other, *T. oculus-solis*, the reputed parent of the early Tulips. But rude guesses are not to be desired, and we may have in the two sections recognised in 1578 the early Tulips as the largest, and the Van Thol, or *Tulpia suaveolens*, as the smaller kind. When we come to Gerard, 1597, we feel that we are on solid ground. He calls it the "*Tulpia*, or the Dalmatian Cap," and describes it as "*a strange and forraïne flower, one of the number of the bulbed flowers, whereof there be sundrie sorts, some greater, some lesser, with which all studious and painefull herbarists desire to be better acquainted, because of that excellent diuersitie of most braue flowers which it beareth.*" Gerard describes fourteen sorts under a general classification of *Præcox*, *Serotina*, and *Media*, the "*timely*" (or early), the "*later*," and "*flowering between both the others.*" The solid ground of Gerard acquires a vast extent in Parkinson, 1629, who enumerates 140 kinds, his classification being the same as that of his great predecessor, comprising early flowering, mean flowering, and late flowering. Parkinson gives us thirty figures of varieties, in some of which we see the "*flame*" and the "*feather*" in a fair state of development, affording delightful promise of the glories that were soon to be revealed and that were to turn the brains of the Dutchmen, and, by the follies of the great Tulip bubble or Tulip mania, prove their consanguinity with the English, who can enjoy a bubble as well as any people in the world. The fact is when John Parkinson was engaged in preparing these figures the bubble was being blown, and it was floating high in the sickly atmosphere of a fool's paradise in the year 1634, and did not burst until 1637. The story of this great folly, as told in Beckman's "*History of Inventions*," is so well known that it would be waste of time for me to treat of it in detail; but I will quote a few particulars from Munting's extracts from the account books of the traders, for the purpose of introducing some other matters that I think will perhaps surprise as well as interest our friends the florists. For one root of a variety called the Viceroy the following articles were offered—namely, 2 lasts of wheat, 4 lasts of rye, four fat oxen, three fat swine, twelve fat sheep, 2 hogsheads of wine, 4 tons of beer, 2 tons of butter, 1000 lbs. of cheese, a bed, a suit of clothes, and a silver beaker, the aggregate value of these articles being 2500 florins. In 1636 Henry Munting sold to a merchant at Alkmaar a Tulip root for 7000 florins, but before it could be delivered the price had fallen, and by agreement the merchant paid 10 per cent., so that Munting pocketed 700 florins for nothing; but it is recorded he would rather have delivered the root for the 7000! One man made by this trade a little fortune of 60,000 florins in the course of four months; so we may conclude that the Dutch people were as much excited about Tulip roots in 1634 as the English people were about railway scrip in 1845. But I quit this part of the subject by saying that the florists were in no way, or only in a shadowy way, mixed up with this folly; the speculators were noblemen, farmers, pedlars, sailors, and chimney sweeps. They knew nothing and cared nothing for Tulips, and they very rarely saw the bulbs they traded in, and probably many were bought and sold that never existed, the mere names serving as materials for speculation.

It is a very interesting question, however, as to what particular class of Tulips gave rise to the morbid excitement, and fed it with such few floral facts as were absolutely needful. A Tulip-grower of the present day would, *à priori*, declare that the late Tulips alone, with their noble forms and fine feathers, would suffice to afford the

inspiration. It is a singular fact that definite information on this point is very difficult of attainment, for the writers who should be able to speak authoritatively will be found to differ; some asserting that the Tulips of the Tulip mania were late Tulips, and others with equal confidence declaring that they were early Tulips. The Rev. William Hanbury, in his great work on "Planting and Gardening," in two folio volumes, 1771, page 859 of the first volume, says without hesitation, "The early species were the sort of Tulips that were so much coveted in the above-mentioned period, and for the bulbs of which, singly, such extravagant prices were given." The list in Parkinson's "Paradisus" long ago suggested to me that the famous Tulips of the seventeenth century comprised the two great divisions; for he wrote so near the time of the outbreak of the mania, and figured and described the several sections then recognised with such evident appreciation of the high merits of each, that it could not be expected the tide of public favour should suddenly contract to one narrow channel to compass only one class of these splendid flowers. I am now enabled to say without hesitation that the famous Tulips of the middle of the seventeenth century comprised both early and late varieties; and moreover, I can declare to you that some of the most famous of that day are at this day in cultivation, and are much prized for their beauty! In my endeavour to solve the riddle I have been greatly assisted by Mr. J. H. Krelage of Haarlem, who possesses a remarkably fine collection of books, pictures, and miscellaneous memoranda illustrative of the history of the Tulip, and he has generously put himself to much trouble to furnish me with original matter for this discourse.

To sum up the results, the Tulips of the bubble period were of all classes, but the principal were of the sections now known as Early and Late. A variety known as Zomerschoon, which was sold for 1010 florins, is still in existence; it belongs to the Late Rose class. The celebrated Admiral Liefkens was a Late Rose. Admiral Van Enkhuizen was a Late Rose. The mighty Semper Augustus must of course have special attention; of this it is said there were at one time only two roots available for commercial purposes, for one of which an offer was made of 4600 florins, a new carriage, two grey horses, and a set of harness. For the other a man agreed to give for a root twelve acres of land. Well, and what sort of thing was Semper Augustus? I asked my friend the Rev. F. D. Horner if he could give me any distinct idea of the style and complexion of Semper Augustus, and he replied indefinitely, but making a very good guess, as will be seen. He says, "I have pictured him in fancy's eye as a rough bizarre of spattery flame, and with skips in feather, long in the cup and thin in petal, foul in stamen, and perhaps base in base—in fact, with a touch of all the faults and blemishes which we have led the Tulips through to purity and beauty." Mr. Krelage is enabled to say, by means of the drawings in his possession, that the original Semper Augustus was a Late Rose, but there was, he adds, "a Bizard of this name which exists yet at present, and of which some bulbs were lately offered to me by some of my friends here."

So far as to the late Tulips of the speculative period. Now for the early ones. The early Tulip we know as Lac Van Ryn was of the number, and was sold for 175 florins. The Geil en Rood, which was sold for 235 florins, was an early Tulip. A very rectified form of Wit en Rood borde, which was sold for 2000 florins, was an early Tulip. Thus we may see that the two leading classes of Tulips were about equally favoured, and the case, as presented by Parkinson in his classification of 140 varieties, is fully justified by the facts at our command. It is to be hoped, however, that those severe florists who turn up their noses at early Tulips will for the future abstain from so distressing the muscles of their noses, as also of making known their possible lack of catholicity, for history has decided that the early Tulips have some technical merit, and it is always folly to oppose the stream that carries with it all the wrecks of time that are gifted with any degree of buoyancy.

Having treated the subject thus far historically let us now hastily regard it from the floral or artistic point of view. There are Tulips of many kinds, and their distinguishing characters are obvious to the most casual observer. Between the clear self yellow or white of a Pottebakker and the feathery pattern of a fine show Tulip the difference is so great that it really does not need to be pointed out. The alphabet of the tulipist may be learned in less time than the alphabet of our literature. But when we quit the elementary stage and plunge into details the parallel holds good, and it is about as hard to understand the details of the Tulip fancy as the intricacies and involutions of expression in English literature. But it must be added that the hardness is softened by its sweetness. It is a laborious task to master all that is required to be known by one who would pass judgment authoritatively on florists' Tulips, and it is not less hard—perhaps more hard—to acquire the knowledge and judgment required for the criticism of English authors from Chaucer downwards.

The early Tulips are judged by form and colour and general effectiveness, but the late Tulips are judged by a most severe judgment as to their form and the symmetry and purity of their markings; and an immensity of knowledge is required for the performance of the arduous task in a satisfactory manner. In the late Tulips some very strange characters are required, such as flames and feathers, of which we see but little in the early Tulips. Consequently at this stage of the story we come upon another of the peculiarly interesting points in the history of the Tulip—it is that which the florists term the "breaking" of the self-coloured flower into one variegated with stripes

and lines that are known as flames and feathers. The florists have perhaps said enough in respect of this wonderful process, but the biologists have not even yet in their ardent search after illustrations of evolution taken hold of the fact as of scientific interest. We sow the seeds, and the plants that rise therefrom produce in due time their flowers. But these flowers have but one colour, and they may be called selfs, but as a rule they are called Breeders. Now, these one-coloured Tulips are carefully scrutinised, and those that are considered deficient of form and substance are destroyed, the very finest of the breeders only being retained for further cultivation. The hope of the florist from this moment is to see his selected breeders break. As a matter of course all kinds of methods and tricks have been resorted to for the promotion of the much-desired "breaking," but only one secret has Nature and Time ever revealed to the anxious watcher over a bed of breeders. Yes, there is one secret, and to realise fully the capabilities of a breeder Tulip we have only to exercise patience. If we are not patient Nature will not move in our behalf; and if we are patient she will be none the less immovable, but will just take her own time, and when her time arrives the self-coloured Tulip will abandon its self colouring and appear with flame or feather, or both combined, a gratifying and glorious reward for the pains and patience of its possessor.

It may appear from this statement that the art of man has but little to do with the characters of the flamed and feathered, or, as we sometimes term them, the "rectified," Tulips. But here we encounter another of the curious features of this fascinating subject, for although the tulipist cannot by any science or any trick compel his breeders to break—and they will do it when they are in the humour, or perhaps never do it at all—nevertheless, the kind of break that may occur, and the style and fashion of the flower throughout, are under his control, and if he does but co-operate with Nature, and as little as possible stand in the way of her normal working, he may ensure the production of a race of flowers of a type determined by himself. To sum up this matter, we must bring to bear upon the production of Tulip seed a certain amount of science and taste, and having done this we must wait for the results. It is thus that distinct strains or races of Tulips have been established, as in one case the Chellaston Tulips, in another the Stapleford Tulips, and so on. We may begin with the selfs, but we must reserve for stud purposes those that have acquired the gorgeous stripes, and in due time we may expect their progeny to take after their parents, and thus keep us rich, and so reward us for our forethought. Thus, having found the Tulip quite unique in its manner of assuming the garb that has made it so renowned, we are now enabled to restore it to the rank of any ordinary flower, and see in its mysterious flames and feathers, and all the characteristics of its carriage and form, an illustration of the Shakesperian doctrine—

From fairest creatures we desire increase,  
That thereby Beauty's Rose might never die.

#### COVERING WALLS IN STOVES.

THE back walls in these structures are often bare and unsightly, and therefore the following outline of a successful mode of rendering them attractive will be useful to those who wish to effect such a purpose in the stove. Fix flat iron bars up the wall about a yard apart. The holdfasts should be either cemented or leaded in: wood should not be used, or the holdfasts require replacing every alternate year. The upright bars should have holes either punched or drilled through them 2 inches apart, through which galvanised wire can be run the whole length of the house in single wires. Another plan is to affix to the uprights on the face of the wall 2-inch-mesh wire netting. When wires alone are used very rough turf must be employed for packing next the wall, with small additions of leaf soil and peat to every layer of turf until the whole is filled, the space between the wall and wire being 3 inches. The wire netting should not exceed 18 inches in width, it being necessary to fill the space up, as the netting is attached to the upright bars. Where moss is plentiful it may be used between the netting and the soil. The compost must be pressed in very firmly, as a hollow space will soon be the result if it is placed in loosely. Besides a groundwork of Selaginellas pricked in about 6 inches apart the following are suitable:—*Begonias* of the ornamental-foliaged varieties; *Tradescantia discolor*, *T. vittata*, and *T. zebrina*; *Panicum variegatum*, *Gymnostachyum Pearcei*, *Adiantum cuneatum*, and *Pteris serrulata*. These should be about 2 feet apart; also a few young plants of *Cissus discolor* add considerably to its beauty. Every care must be taken to keep them moist by syringing twice every day, especially when first inserted. This mode of covering a wall is one of the most beautiful, amply repays for the trouble, and invariably gives great satisfaction when artistically executed.—A.

CALANTHES AT DRUMLANRIG.—Mr. Cox (page 215) appears to require further information about the above. It is well known that they are second to none in the kingdom, and as I hope Mr. Thomson will tell us in these pages the details of his culture I will not speculate on it. Had I found them with small pseudo-bulbs

nothing would have been said about their promise of flower, but as they might be compared to 3-inch flower pots turned upside down little knowledge was wanted to predict their flowering capabilities. When an experienced Pine Apple grower sees a batch of fruitless plants with short thick stems and broad sturdy leaves he can say with safety that they promise well for fruit. This rule applies to many plants, amongst others to *Calanthes*.—PARAGON.

#### PEAS.

WITHOUT wishing to enter into any controversy as to the hardness of early Peas, Mr. Iggulden will find in my notes at page 126 that I stated "Early Peas I have found will not succeed well if sown on heavy land, the wet in my opinion being more prejudicial than the cold." The writer I name also asserts at page 186 "that late autumn sowing on cold heavy soil is often a waste of labour and seed," so I conclude we are both of one mind as regards that part of the question. My remarks in a former paper applied to sowing on a south border, and as a general rule the soil in that part of a garden is lighter and more friable than the open quarters. Mr. Iggulden also asks, "What if the early winter be mild, followed, say, towards the end of January by severe frosts?" The weather may be mild—it was last year up to Christmas; and if it should be so throughout the greater part of January, the sun has so little power in warming the soil that the Peas would make no more growth in January than they would in a week or ten days in November. Peas endure cold better than is generally supposed. Several rows 2 inches in height on a south border, and a few rows in open quarters, withstood 12° of frost a fortnight ago, and with the wind in the north-east, without looking any the worse, although a sunny day followed. But it is, as your correspondent says, the cold and wet heavy soil that make root-action defective. The soil in November perhaps is not so dry as could be wished for sowing seed, but by having it dug on a fine day when turned over and exposed for four or five hours, it will not be so wet but that the seed may be sown. It will not require treading-in to make it firm, as may be the case in May or June. Certainly a large quantity of Wheat and Beans are sown on farms at that time of year whatever may be the condition of the soil, and that is not usually in such a pulverised condition as that of a kitchen garden under spade culture.

Mr. Iggulden asks what difference there is between Yorkshire Hero and Veitch's Perfection. Possibly there may not be much; there is not between many other vegetables, and flowers also. Six or seven years ago I sowed both varieties the same day on light gravelly land. The only difference I found was this—the first-named produced pods fit to pick a week earlier than the other, averaged 6 inches taller in growth, with a little difference in the shape of the pod. Both are of excellent quality. Huntingdonian is undoubtedly a first-rate Pea; it has finer pods than Champion of England, and is equal to it in cooking qualities. I doubt if it surpasses it, but that may be a question of taste. I have grown it three years in succession, but find I can pick more pecks of Peas from a given quantity of seed or a given number of rows of Champion than I can from Huntingdonian. Both these should be sown in rows at least 5 feet apart.

I desire to thank your correspondents for the useful information they have given me as to the best method of preparing paraffin tubs for plants.—A. HARDING.

MR. IGGULDEN is no doubt a good cultivator of vegetables, and is well acquainted with modern varieties. His writings, however, imply that he has not had to combat the inclemencies of a northern temperature, and that he is not old enough to remember the varieties of Peas that were grown say thirty years ago. Had he practised his calling in Yorkshire instead of in the south of England he would not advocate sowing Peas early in November, nor would he labour under the delusion that Peas are so tender as he suggests, and that autumn sowing is of little use. I have sown Peas in the autumn for thirty years, and during the whole of that time I have certainly not had five failures, and the rows have often been as productive as those sown in early spring, and always a week earlier. Peas that are sown so that they only just appear fairly above ground before winter are as hardy as Cabbage plants, and yet I presume your correspondent plants these in the autumn.

Mr. Iggulden evidently does not know the true Yorkshire Hero Pea. It is a little taller than Veitch's Perfection, rather smaller in the foliage and more slender in the stems, produces a greater number of tendrils, and perhaps of pods, but the latter are not quite so large as those of the other variety. The Yorkshire variety is also earlier than Veitch's. I suspect, however, it is somewhat the

custom in seed houses to supply both varieties from the same bag. Can Mr. Iggulden inform me who was the raiser of Huntingdonian and its parentage? This information will perhaps show that it is not the true old Champion. Those who will save seed from the large instead of the small pods of the Champion will, I fancy, soon have a "Huntingdonian." The Champion of England Pea, as ordinarily sold, is not so fine as it was a quarter of a century ago. I could name other Peas that have generally degenerated, and selected stocks of them have sprung up under new names.—A YORKSHIRE GARDENER.

#### A FEW REMARKS ABOUT ROSES.

I AM glad to notice the tide of feeling against cultivating so many standard Roses becoming stronger and more pronounced. The last three winters must have taught all who grow them in quantity how expensive the "keeping of them up" is. They are much more expensive to purchase, take much more labour, are much more likely to suffer from gales of wind, and in my experience six standards are injured by frost for one dwarf, whether the latter are on their own roots, or on the Manetti or Briar. All winter and early spring few objects are more unsightly than a standard Rose. A great number of dwarfs and standards are grown here, and the havoc by last winter's frost among the latter has been terrible, while dwarfs have escaped wonderfully. In one bed alone of between three and four hundred standards fully one-half have perished, while the others are very much crippled. In more exposed beds the standards have been nearly annihilated.

Is it not matter for regret that so many comparatively tender sorts of Roses are cultivated to the all but exclusion in many instances of the fine old hardy Moss and Cabbage Roses? What can be more beautiful than beds of Moss Roses? and the sweetness of the Cabbage Rose is peculiar to itself. Then there are the good old hardy and almost perpetual Chinas or Monthly Roses. Do these have the patronage they deserve? The two former flower only once a year it is true, but to how many lovely flowers cannot the same objection be applied? We seldom meet with the delicious Cabbage Rose properly prepared for forcing into bloom in early spring, yet what is more lovely or deliciously scented? We question if even the Teas can excel it in this point.

Would it not be much more satisfactory to grow fewer at least of standard Roses, and devote the extra labour and expense they entail to these two fine old Roses? I have long thought that Rose-growers have far too many varieties. The names are numerous, but for all practical purposes a few varieties of the best of each colour grown in quantity is more satisfactory than such an endless array of names that often cause more confusion than pleasure. For instance, a small grower with, say, about two hundred plants might find it much more satisfactory to grow twenty-five instead of fifty varieties.—D. THOMSON.

#### FRUIT-TREE PLANTING IN CORNWALL.

I QUITE agree with "R. I. L." (page 191) that farmers in Devon and Cornwall do not seem to think their orchards of much consequence. This is to be deplored; but the fact is, the farmers often have a short lease, so that it is scarcely to be supposed that they will uproot an old tree and plant a new one in its place. When there is an abundant crop the overplus is either given to the pigs or left on the ground to decay. In the event of the orchard ground being laid down with grass the cattle are allowed to roam everywhere, not the slightest protection being offered the fruit trees. The market gardeners here, however, pay more attention to their fruit trees, and with good results. Between the rows of Apple trees Gooseberries are planted, and it is strange if one crop does not prove satisfactory. The Keswick Codlin and Lord Suffield are the principal varieties grown for general cropping. Trial on a small scale has been made with both Newtown Pippin and Baldwin, but at present I do not know with what success. Many acres are taken in for fruit cultivation in Cornwall, and are planted with Raspberries, Strawberries, Apple trees, &c., and more will, I think, be planted next year, and not underneath trees but in the open.—W. ROBERTS, *Penzance*.

THE GLOXINIA.—These can be grown by anyone who has a Cucumber frame to start them in, and a greenhouse to grow them in afterwards. If there are Vines in the same house so much the better, as Gloxinias require shade when in bloom. We shake the plants out of the pots and place them closely in boxes or pans, and slightly cover with light soil or cocoa-nut fibre refuse, and place in the frame, where they will soon start and be ready to pot off

in a few weeks. When potted before starting they are very liable to decay. Seed sown now will produce plants that will flower by autumn and make fine tubers for the following summer.—STIFFORD.

#### CHOROZEMA CORDATUM SPLENDENS.

AMONGST beautiful decorative plants at this season of the year this *Chorozema* ranks very high with its distinct lovely Pea-shaped flowers. It is easy of cultivation, and admirably adapted for the conservatory, small plants being also suitable for the embellishment of rooms, and a well-grown specimen is very attractive in the exhibition tent. It is also suitable for planting out either against pillars or to cover walls in cool houses, but when employed for this purpose good drainage must be provided, or failure is almost sure to be the result.

Propagation is effected by means of cuttings, which root readily, or from seed, which some consider the better mode. Having raised plants both ways I have never found much difference, the seedlings being perhaps a little more robust. As a rule the seed sets freely, and should remain upon the plant until thoroughly ripened, then sow it at once in a pan filled with fine peat and sand. The seeds should be well covered with similar compost, watered, and placed in moderate heat, and in a short time they will germinate. When large enough the plants should be potted singly in 2-inch pots. Cuttings are plentiful after flowering is over. The young shoots should be selected and taken off when about 2 inches in length with a small heel, and a number placed in a 5-inch pot filled with sandy peat and half an inch depth of silver sand on the surface. When the cuttings are inserted carefully water them, plunge the pots in slight bottom heat, and cover with a bellglass. The cuttings must be shaded from strong sunshine, and sprinkled with a fine syringe from time to time to keep them fresh. They will soon form roots—in fact, in shorter time than the seedlings will appear if sown at the same time as the cuttings are inserted. They must then be placed singly in 2-inch pots, and again placed in bottom heat for a week or ten days until the roots start freely, when it can be dispensed with altogether and the plants gradually accustomed to a lower temperature. A night temperature of 55° will be ample after they are established, and they will make much greater progress than if subjected to a greenhouse temperature from the first. The points of the young plants must be taken out as soon as rooted to induce a branching habit. When the small pots are full of roots the plants should be shifted into pots 2 inches larger, which will be large enough the first season, and if attention is paid to stopping the shoots bushy little plants will be produced by autumn. After being placed in 4-inch pots a cold frame will be the best position, with a bottom of ashes or any cool moisture-holding material. After this potting the frame should be kept close for a time, the plants being well syringed overhead and shaded during bright sunshine. The plants must be gradually hardened as they become established, ventilating the frame freely on all favourable occasions until autumn. During winter a temperature ranging from 40° to 45° will be suitable. They will endure a much lower temperature, but with young plants it is not advisable, as the roots do not remain so active, nor will the young plants start into growth so freely in the spring. Early in the year, say in the month of February, the plants should be placed in 6-inch pots, which must be well drained. The house must be kept close at first after potting, and the temperature raised a few degrees. The plants will soon start vigorously into growth, and must as the season advances be hardened again by cool treatment. If good attention is paid to them the largest will be ready for 7 or 8-inch pots by the end of July, and the shoots should not be again stopped if wanted to bloom during the following spring.

This *Chorozema* can be flowered every season from the cutting stage, but it is wise to sacrifice the bloom of one or two plants until creditable specimens are formed, which can be obtained in three years. After the first season growth should be rapid, and potting must be done twice each season until the plants are in 10 or 12-inch pots, which are large enough for all ordinary specimens, unless required for exhibition.

Potting must be carefully done in all stages. The old ball must not be broken nor the roots disturbed to any extent when removing the crocks. The soil, which should consist of peat and coarse sand, should be pressed firmly into the pots. They will do well in a mixture of peat and loam, but all peat is preferable, as it is not so liable to become sour. Watering in all stages must be carefully attended to, especially for some time after potting, and the roots are quickly injured by an insufficient supply, red spider soon attacking the foliage. The syringe should be liberally employed twice daily during the summer months. Training is very simple, and a few stakes only are required at first to support the growths.

When sufficient growth is made the plants can be trained upon a balloon trellis, as they are shown to greater advantage upon it than any other shape. Plants in 8 and 9-inch pots trained on small trellises about 18 inches high are charming and distinct objects for conservatory decoration. Beautiful little plants for vases and the front lines of plant houses can be grown in 5 and 6-inch pots.—WM. BARDNEY.

*CHOROZEMA CORDATUM SPLENDENS* undoubtedly deserves to be much more generally known. Several other species and varieties are grown, but for general utility the one under consideration can scarcely be surpassed. The flowers are pea-shaped,

Fig. 53.—*Chorozema cordatum* var. *splendens*.

as the woodcut shows, the broad petal or standard being of a rich orange red colour, with a lighter blotch near the base; the other portion of the flower—the wings and keel, being purple. The leaves are bright green, ovate in form, and having a spinose margin. The habit is rather loose and straggling, and, as has been stated, the plants require training to a trellis of some kind, when they become specimens of moderate size. Mr. Roberts, gardener to the Baroness Rothschild, Gunnersbury Park, has a high opinion of the plant, and grows a number of specimens mostly trained in a globular manner. These are now in excellent condition, and the accompanying woodcut represents a spray from one of them.

The species is a native of the Swan River territory, whence seeds were obtained by Mr. Robert Mangles about 1833. They germinated, and the young plants were freely distributed during the three or four following years. The variety *splendens* is an improved form of the plant, surpassing the type both in the size and colour of the flowers, but when or where it originated I do not know.—L. C.

*SIPHOCAMPYLUS HUMBOLDTIANUS*.—For some time past a specimen of this plant has been flowering in one of the compart-

ments of the new range at Kew. It is well worth growing in a stove or intermediate house, the latter, perhaps, suiting it rather better, as the growth is more robust and the flowers last longer in a cooler temperature. In habit it is moderately compact and bushy, with shining dark green ovate leaves, and brilliant orange-scarlet tubular flowers produced singly in the axils of the leaves near the summits of the shoots. The corollas are strangely bent or curved downwards, and have a small limb of five acute segments, which are of a lighter colour than the tube, the throat being yellow. In striking contrast with these lively tints are the deep blue anthers, which are united in a ring round the style, and protrude a short distance beyond the mouth of the corolla. The stigma is two-lobed, and is surrounded by a hair which acts as a kind of brush; and when the style is growing and forcing the stigma through the ring of anthers, the lobes being then folded face to face, the pollen is removed and pushed out of the flower. After this the two lobes of the stigma expand and become receptive. This peculiar process closely resembles that which takes place in many members of the natural order Compositæ. The plant is a native of Peru, and first flowered at Mr. W. Bull's nursery in 1866, from which a coloured plate was prepared for the "Botanical Magazine." Three years later Mr. C. Green exhibited a plant before the Royal Horticultural Society and obtained a first-class certificate for it.

### ROYAL HORTICULTURAL SOCIETY.

MARCH 22ND.

AFTER a week of brilliant spring-like weather it was unfortunate that a snowstorm accompanied by a keen cold wind should have prevailed on the morning of the first Show of spring flowers. The inclemency of the weather, however, did not prevent exhibitors staging beautiful collections, although it could not fail to have a deterrent effect on visitors; yet these were numerous, select, and appreciative, a change to clear and sunny weather fortunately occurring shortly after noon. The display was satisfactory in the highest degree; rarely, indeed, has it been equalled, as is evidenced by the large number of gold medals awarded, no less than eleven having been adjudged to the chief exhibitors. The general excellence of the plants staged was remarked by many visitors, and all seemed to have done their best to render the Show as successful as possible. The Floral Committee's duties were comparatively light, as the bulk of the plants were staged in the conservatory, but the Fruit Committee had not a single exhibit to adjudicate upon—a remarkable and rare occurrence.

#### SPRING SHOW.

The conservatory bore an unusually gay aspect, and rarely has a greater number of beautiful plants been arranged there thus early in the season. Hyacinths were of course the chief feature, but there was abundance of other plants, so that the general appearance was not only bright but varied. A stage extended down the centre of the broad path; this was entirely occupied, and tables on each side were also filled with floral treasures, the general disposition of the groups being highly creditable to the Superintendent.

Three special prizes were offered by a Fellow of the Society, and these were supplemented by two others, the class being for nine pots of Hyacinths and the same number of Tulips. The competition was good; five exhibitors entering the lists, though the two first were far ahead of the others. The silver cup was allotted to Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, who staged an even collection of Hyacinths and Tulips, all the plants being in excellent condition. The Tulips represented were white Pottebakker, Van der Neer, Proserpine, white Joost Van Vondel, Keyzers Kroon, Vermillon Brilliant, and Fabiola; all were very fine, the flowers neat, and the colours bright. The Hyacinths had massive spikes with good bells, the varieties being Grand Lilas, Gigantea, Koh-i-Noor, Marie, Mont Blanc, Vuurbaak, Lord Macaulay, King of the Blues, and Le Grandesse, all admirably grown. Mr. Moorman, gardeuer to Miss Christy, Coomb Bank, Kingston-on-Thames, was a very close second with a good collection, the Hyacinths not quite so fine as Mr. Douglas's, but the Tulips were rather better in general condition. One yellow variety of Tulip named Mon Tresor was especially noteworthy for the excellent form of the flowers and the purity of their colour. Among the Hyacinths the most noticeable were Czar Peter, very fine; and Lord Derby. Mr. C. Parker, Clay Hall Works, Old Ford, E.; Mr. J. R. Roberts, 79, Mile End Road, E.; and Mr. C. J. Dance, 437, Mile End Road, E., were respectively awarded the third, fourth, and fifth prizes for rather small but healthy specimens.

Of the numerous collections exhibited by nurserymen and others the most imposing was that from Messrs. J. Veitch & Sons, Chelsea, which occupied at least 100 feet in length of the central staging, in addition to a group at the end of the conservatory. First were the Hyacinths, which alone constituted a magnificent display, for probably finer plants have never been exhibited. Massive and compact spikes, large flowers, and clear bright colours indicated not only the excellence of the bulbs but the carefulness of the culture bestowed upon them. The varieties were also numerous, and an excellent oppor-

tuity was afforded visitors of making a selection; this many seemed to appreciate, for note-books and pencils were in great request, especially among the ladies. Over two hundred plants were shown, and the Council signified their high estimation of the group by awarding a gold medal for it. Amaryllises were also staged by the same firm in large numbers, many handsome varieties being represented, the symmetrical form of the flowers being especially notable. Their bright colours, too, contrasted well with the Hyacinths, but the latter constituted the attraction of the day, though a gold medal was also awarded for the Amaryllises. Following them were groups of Spiræas, dwarf Guelder Roses surprisingly well flowered, the pretty Rhododendron Early Gem, with specimens of the snowy white-flowered Japanese Quince, *Pyrus japonica alba nivalis*, which were flowering very freely. In addition to these a group of Camellias in pots was arranged near the entrance to the conservatory. They comprised healthy well-grown plants 4 to 6 feet in height, and bearing some excellent flowers. Another gold medal was awarded for this group, being the third obtained by Messrs. Veitch on this occasion—a fact which in itself speaks highly for the quality and beauty of their exhibits.

Still keeping to the chief exhibits of bulbs, the next deserving attention was the group from Messrs. Osborn & Sons of Fulham. This comprised about 120 Hyacinths and fifty Tulips, representing a very large number of varieties generally in admirable condition, among the Hyacinths; the spikes being large, the bells of good shape, and the colours good. The Tulips were not so fine, but a good selection was shown, well meriting the gold medal awarded for them. A similar award was made to Messrs. Wm. Cutbush & Son, Highgate, London, for large and handsome groups, comprising about a hundred Hyacinths notable for the size of the spikes and the good selection of varieties, which well entitled them to the medal awarded. They also had a pretty group of Azaleas of the indica and mollis types. The former were compact specimens in 24-size pots and remarkably well flowered. Six boxes of Camellia blooms were staged, including good examples of Bealii, Miniata, Countess of Orkney, Saccoi nova, Teutonia, Mathotiana, and the old Alba plena. Some small Camellias in pots were also shown.

The chief amateurs' collections were the two following, for both of which gold medals were awarded. Captain Patton, Alpha House, Regent's Park, had a large and handsome group of Hyacinths, with a back row of Spiræas and Dielytras arranged alternately, and an edging of *Isolepis gracilis*. The Hyacinths were in admirable condition, the spikes massive, and the colours good. They appeared to have been very well grown, as the foliage was well developed. Mr. Moorman had also an extremely fine group comprising about a hundred Hyacinths and 120 Tulips, all in very satisfactory condition. The Tulips in particular were in fine form, the flowers neat, and the colours bright and diversified. The whole group was very creditable to Mr. Moorman's cultural skill, and he deserved the honours he received.

The miscellaneous groups were uncommonly fine, the most remarkable being that from Mr. B. S. Williams, for which a gold medal was awarded. This handsome group comprised 120 Orchids in excellent condition. *Cypripedium villosum* was represented by several large specimens with a number of flowers. *Phaius grandifolius* was also in fine condition, and a number of Dendrobis. The rare little *Lælia harpophylla*, with small orange-coloured flowers, was represented by several specimens, and many other both rare and beautiful Orchids indicated not only the extensive stock of the Holloway nurseries but the energy of the proprietor in bringing them out on such an unpropitious morning. The General Horticultural Company (John Wills, Limited), Onslow Crescent, Anerley, and Regent Street, exhibited an extremely graceful group of plants that was very much admired by visitors. It chiefly consisted of Palms, the elegant *Cocos Weddelliana* predominating, with *Adiantums*, *Dracænas*, *Crotons*, and other fine-foliage plants. The central plant was a fine specimen of *Anthurium Schertzerianum*, bearing over two dozen large spathes, and on each side of this were nooks filled with Forget-me-nots, with a few plants of *Odontoglossum cirrhosum* gracefully intermingled, and brightened by some *Masdevallias*, small *Anthuriums*, and Azaleas. A gold medal was awarded as a recognition of the taste displayed in the arrangement of this charming group. A gold medal was also awarded to Messrs. Paul & Son, The Old Nurseries, Cheshunt, for a collection of handsome Roses in pots very well flowered. Among them the following were especially notable:—Annie Laxton in a 10-inch pot with twenty flowers, Madame Lacharme with about thirty blooms, and La France with twenty blooms. Other noticeable varieties were the Duke of Teck, large flower, rich rose colour; Madame Alphonse Lavallée, with a fine rich pink bloom; and Gloire de Bourg la Reine, intense crimson. Mr. J. Aldous, Gloucester Road, South Kensington, was awarded a silver Banksian medal for a tastefully arranged group of flowering and fine-foliage plants, including Azaleas, Spiræas, Hyacinths, Tulips, Mignonette, Pelargoniums, Palms, Ferns, &c. The edging was very pretty, consisting of plants of *Scilla siberica* and *Isolepis* alternately. Henry Little, Esq., Hillingdon Place, Uxbridge (gardener, Mr. Wiggins), was awarded a silver Flora medal for a collection of Cyclamens and Cinerarias in very good condition, the colours of the latter being particularly bright. Mr. H. B. Smith, Ealing Dean, obtained a gold medal for an extensive group of Cyclamens, flowering freely and comprising over two hundred plants. Messrs. William Paul & Son,

Waltbam Cross, were awarded a silver Banksian medal for a collection of Camellia blooms in the customary fine condition. The varieties that were particularly noteworthy for their excellence being Cup of Beauty, bluish, good form; Marchioness of Exeter, large blooms, rich crimson; and Countess of Derby, a beautiful pink variety. Messrs. H. Cannell & Son secured a silver Banksian medal for a collection of Cinerarias, the colours of which were remarkably bright. Messrs. Smith & Lark, Kensington, exhibited several baskets of cut flowers very tastefully disposed, and specimens of the Bentley Patent Water Spray were also shown by the London agents (The General Horticultural Company). A silver Banksian medal was awarded to Mr. J. Douglas for six handsome specimens of *Deutzia gracilis*, extremely well flowered, and a similar award was made to Messrs. Barr & Sugden of Covent Garden for a collection of Cyclamens.

The following new Hyacinths were exhibited by Messrs. Veitch, and some surprise was expressed by critical visitors that none was certificated. *Primrose Perfection*.—Spike large and moderately compact; bells of medium size, rather narrow petals, but of an excellent clear yellow tint: indeed it is one of the best yellow varieties. *Queen of the Blues*.—Spike very compact, the floral portion 5 to 6 inches long; bells finely formed, colour light blue. *Beatrice*.—Spike of moderate size; bells of good size, and creamy or bluish white. *Cesar Alexander*.—Spike very large and compact; bells very neat in form, and rich dark blue in colour. *Sir Frederick Roberts*.—Spike close and of good form; bells symmetrical, bright rosy pink, darker in the centre of the petals: a beautiful variety. In addition to these the varieties named below were some of the best in the various groups. *White*.—La Grandesse, Mont Blanc, L'Innocence, Alba maxima, Madame Van der Hoop, Lord Shaftesbury, La Franchise, Baroness Van Tuyl, British Queen, and Snowball. *Dark Blue*.—Christy Minstrel, General Havelock, Duke of Connaught, King of the Blues, Mimosa, Sir Harry Barclay, Prince Albert, and Argus. *Light Blue*.—Grand Bleu, Lord Derby, Cavaignac, Grand Lilas, John Bright, Czar Peter, Princess Mary of Cambridge, Grand Monarch, Lord Byron, and Electra, the last-named, a handsome variety, certificated last year, and likely to become valuable for exhibition. *Red*.—Prince Albert Victor, Von Schiller, Pelissier, Etna, Lord Macaulay, Solfaterre, Garibaldi, Vaurbaak, and Linnaeus. *Yellow*.—L'Or d'Australie, Bird of Paradise, Obelisk, Ida, King of Yellows, and Jonquillon. These were all single varieties, very few double forms being shown.

#### COMMITTEES.

**FLORAL COMMITTEE.**—Dr. Kellock in the chair. The exhibits in the Council-room were not very numerous, being confined to a few new plants, and some of special interest. Messrs. J. Veitch & Sons of Chelsea staged a small collection of plants, including a plant of a species of *Amelanchier* bearing racemes of flowers with narrow white petals; *Clematis coccinea*, an elegant species, with small three-lobed leaves, and solitary pale rose-coloured bud-shaped flowers. A deep scarlet-coloured variety of *Azalea indica* named Comte de Gomer was shown in good condition, and a semi-double pink and white form named Empress of India was similarly noticeable. Several new Hyacinths and Amaryllises were exhibited, one of which was certificated and is described below. Mr. Charles Winn, Birmingham, sent a plant of *Masdevallia Roezlii* bearing a rather large flower, something in the way of *M. Chimara*; the sepals are thickly spotted and streaked with a very dark brown, almost black; the lip being small, fleshy-coloured, and shell-like in form. Mr. C. Green, gardener to Sir George Macleay, Bart., Pendell Court, Bletchingley, exhibited a specimen of *Pitcairnia corallina*, a species with leaves 3 or 4 feet in height, from the axils of which started a spike 1½ foot long of bright coral red flowers 2 or 3 inches in length. Specimens of *Fuchsia splendens* and *F. cordifolia* were also sent in flower, well showing their distinctive character. A vote of thanks was accorded. Mr. George, gardener to Miss Nicholson, Putney Heath, exhibited a collection of *Abutilons*, representing several good varieties.

Mr. B. S. Williams, Upper Holloway, sent several new plants, including *Imantophyllum cruentum*, with a fine truss of orange scarlet flowers; *Cypripedium Turneri*, *C. politum*, and *C. chloroneuron*, and specimen of *Chirita asparagoides*, a neat plant resembling an Asparagus, as the name signifies. Mr. H. B. Smith, Ealing Dean Nursery, sent several handsome Cyclamens, the most remarkable being Queen Victoria, white, of great size and good substance, the petals very broad and rounded. Rose d'Amour was a good crimson variety, and Prince of Wales similar. Henry Little, Esq., Hillingdon Place, Uxbridge, sent several Cinerarias and Cyclamens, one of which was certificated. A vote of thanks was accorded to Mr. G. Smith, New Villa, Hedge Lane, Edmonton, for a collection of Cineraria blooms remarkably good in colour. Messrs. Osborn and Son, Fulham, sent three new single Hyacinths, named respectively Empress of India, good red; Queen of the Blues, pale blue; and Royal Blue, very dark blue, large bells, white centre. Messrs. Charles Lee & Son, Hammersmith and Isleworth, exhibited half a dozen plants of Lilac Charles X. in 32-size pots; they were about 18 inches high, and flowering very profusely. A specimen of *Staphylea colchica* was also shown of similar size. A vote of thanks was accorded. Mr. Salter, gardener to J. Southgate, Esq., Selburn, Streatham, sent a plant of *Odontoglossum Lebmanni*. The flowers have narrow sepals and petals, yellow barred with reddish brown, and an acute brownish lip. Mr. Richard Dean, Ealing, sent a basket of Primroses, including some very pretty varieties, the most noteworthy being Virginia, white; Brilliant, rich crimson; Auriculæflora, maroon; and

Crimson King. Messrs. Wm. Paul & Son, Waltbam Cross, also sent a collection of Primrose seedlings from the variety Scott Wilson, showing a great diversity in the size and colour of the flowers.

First-class certificates were awarded for the following plants:—

*Amaryllis* Mr. Henry Little (Veitch).—Flower of great size and excellent form; petals broad, of good substance, rounded, and rich deep crimson in colour, with a few darker veins and white streaks towards the apex of the petals.

*Fuchsia rubra*.—This plant was exhibited by Mr. Wells, gardener to R. Ravinbill, Esq., Fern Hill, Windsor, and was stated to be a seedling, the result of a cross between *F. Dominiana* and *F. serratifolia*, both of which it resembled to some extent. The flowers were borne very freely, the tubes very bright crimson, 3 to 4 inches long, with small bright scarlet petals. The leaves are elliptical, 4 inches long, and 1½ inch broad, bright green. It was stated that the plant had been in flower since last October.

*Dendrobium lituiflorum* var. *candidum*.—This plant, a distinct variety of a well-known species, was exhibited by Sir Trevor Lawrence, Bart., Burford Lodge, Dorking. It had a growth over 2 feet in length, and bore fourteen flowers with pale yellow lips and pure white petals and sepals.

*Cyclamen persicum Ruby Gem* (Little).—A pretty variety, of neat habit, with flowers of medium size but excellent form, and of a very deep rich crimson colour; in fact, it is scarcely surpassed in the depth of tint.

**SCIENTIFIC COMMITTEE.**—*Plants Exhibited.*—*Masdevallia Roezlii*, by C. Winn, Esq., of Birmingham, received a botanical certificate. A hybrid seedling *Cypripedium Saundersianum*, cross between *C. caudatum* roseum (male), and *C. Scblimii*, by W. Marshall, Esq., Rutland Gate, Belvedere. *Pitcairnia corallina*, exhibited by Mr. C. Green, gardener to Sir G. Macleay of Pendell Court; it received a botanical certificate. *Dendrobium Wardianum*, a spray accidentally broken off three months ago and laid on a table, was in full bloom, bearing eighteen blossoms.

Gall or *Cicidomyia salicis*, a woody gall exhibited by Mr. McLachlan. Conifer Shoots.—Dr. Masters exhibited boughs attacked by a gumming or rather resin-producing disease, forming pustules which burst and liberate resin. The disease kills the Conifers. Dr. Masters exhibited sprays of a Yew in full blossom (male) which had been transplanted at Buckland near Dover. The tree was 8 to 900 years old. Mr. Wilson informed the Committee that two valuable horses were lately poisoned by eating Yew boughs. He exhibited a specimen of *Amelanchier vulgaris*, and alluded to its geographical distribution, being found on Swiss mountains, North America, Himalaya, and Japan.

#### MARÉCHAL NIEL ROSE.

I HAVE in a greenhouse under my charge a Maréchal Niel Rose on its own roots ten years old at the present time, and apparently in the most vigorous health, with hundreds of bloom buds. The mother plant of this was fourteen or fifteen years old last season when removed to make room for another variety, and was then in good health. We have cut from these plants four hundred blooms every year, and could have cut more had they been allowed to extend over a larger trellis. This Rose like many others is more partial to some soils, and I think the chief failures arise from it being planted in too light a soil, which is more apt to cause canker. The compost recommended by Mr. Bardney (page 146), with a handful of charcoal added, I have found to suit it best, with a good drainage.—R. PHILLIPS.

As our readers will remember, we felt it our duty to publish some denunciatory remarks on page 284 of our issue of September 23rd, 1880, relative to a peculiar instance of PRESS PIRACY as described in the paragraph in question. In consequence of our observations Mr. Robinson of the *Garden* demanded of us, through his solicitors, a public apology in terms satisfactory to himself. As the Editor of the *Garden* had transferred to his columns an article from an Irish paper, whose title he gave as the authority of that article, which had been abstracted from our columns without acknowledgment, we conceived that an apology was rather due to us. However, we did not ask for one, nor was any explanation tendered. Instead of this course, which we presume would have been honourable, an action for libel was raised against us. The complainant having certified for a

special jury, the case was tried before Mr. Justice Manisty in the Queen's Bench Division at Westminster on the 22nd inst., and without any witnesses for the defence being called a verdict was at once given in our favour with costs. Such is a brief record of the case, on which we desire to make no comment; but a feature in the case demands notice. We received a letter by post, a perfectly honest and genuine expression of opinion on the part of a correspondent, which we published on the page quoted, and on which the alleged libel appears to have been founded, on the assumption that such letter was either written in the neighbourhood of our office or with our cognisance. There is not the remotest particle of truth in either assumption. We were subpoenaed to produce the letter, which was in Court, but the plaintiff's Counsel, in the exercise of his discretion, did not call for it. The litigation has now ended, and we desire to live amicably with all our contemporaries; and as in the past, so in the future, we shall endeavour not to be the aggressors in any trifling dispute that may arise; and if by any error we should transgress the rules of literary propriety, we shall feel that we can afford to adopt the honourable course of rendering our acknowledgments or tendering our apologies when either can be rightly expected.

— AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Col. R. Trevor Clarke in the chair, the following candidates were duly elected Fellows—viz., Ephraim Burford, Right Hon. Geo. Cubitt, M.P., Major General James Davidson, Mrs. E. A. Eno, Everitt Everitt, Mrs. J. W. Flanagan, R. T. Harding, Mrs. Henry S. King, Frederick W. Lawrence, Mrs. Ries, Archibald H. Secretan, Mrs. Catterson Smith, Richard H. Tidswell, Mrs. Underhill, and Col. Weguelin.

— ON Saturday last Messrs. W. Paul & Son of Waltham Cross had an EXHIBITION OF CAMELLIAS at the Royal Aquarium, Westminster. About twelve hundred blooms were staged, representing over fifty varieties. The majority of the flowers were very fine, all the best varieties in commerce being shown. Some fine Hyacinths and Tulips were also contributed from Mr. Beckwith's nursery at Tottenham.

— MR. CHILD has under his charge an extensive and beautiful display of PRIMULAS AT GARBRAND HALL. The varieties, chiefly the grower's own selection, are excellent; the flowers large, flat, finely fimbriated, circular in outline, and of good substance; the whites pure, and the crimsons bright. One house is entirely devoted to plants of the white variety, and the abundance of flowers produces a beautiful effect, there being no bright colours to mar their purity. In another house there is a similarly satisfactory display of the crimson-flowering forms. In all the plants the foliage is neat, the leafstalks moderately short, and the blade even and regularly cut; the rich green tint—the invariable attendant on careful culture—still farther enhancing the beauty of the plants, the trusses of bloom rising sufficiently high to be clear of the foliage, thus avoiding the unpleasant and too frequently seen extremes of being so tall as to appear weak, or so dwarfed amongst the leaves as to be scarcely visible. The old double white Primula also receives attention, and with the same good results for vigorous health and a bountiful supply of these useful flowers. Mr. Child is a very successful grower of Primulas, and his mode of culture is detailed on page 225.

— WE are requested to state that the BURTON-UPON-TRENT HORTICULTURAL SOCIETY will hold their Exhibitions on June the 22nd and August the 24th. Mr. R. B. Barratt, Abbey Cottage, Horninglow Street, Burton-upon-Trent, is the Secretary.

— REFERRING to GLADIOLUS CULTURE IN SCOTLAND a correspondent writes—"After Mr. Galloway dissolved partnership with Mr. Robertson the latter showed them quite as fine as before that time. The most wonderful spikes I have ever seen were

produced under the care of a manager at Stuart & Mein's of Kelso. He only grew a few dozens, but most of them turned out superb spikes. Your Irish correspondent's mode of early planting would not do here at all."

— THE decorative value of LACHENALIAS IN POTS is well shown at Gunnersbury House, where Mr. Hudson, the able gardener, grows a number of specimens, chiefly of *L. tricolor*, in 48-sized pots, several bulbs in a pot. They are now bearing hundreds of spikes of their pretty tubular red and yellow flowers, producing quite a gay effect upon the shelves of a moderately cool house. The bulbs will flower well for several years in the same pots if supplied with liquid manure; but the disadvantage of allowing the plants to remain too long without a potting is that they become very crowded and irregular in height, which can only be remedied by shaking them out every year, selecting the bulbs that are nearly equal in size for placing together.

— WE are informed that the weekly FLOWER SHOWS AND MARTS at the Alexandra Palace will be recommenced during the present month, as Messrs. Jones & Barber have taken the Palace on a long lease, and have engaged Mr. Forsyth Johnson as Superintendent of these displays.

— ON Tuesday last Mrs. Gladstone presented the prizes at the Bow and Bromley Institute to the successful members of the EAST LONDON FLORICULTURAL SOCIETY. There was a crowded attendance, and the show of flowers was a very fine one. After the distribution a handsome bouquet was presented to Mrs. Gladstone, as also a vote of thanks; in acknowledging which, Mrs. Gladstone observed that the East of London, which had been noted for its smoke hitherto, would soon become famous for its flowers.

— THE schedule of the FARNINGHAM ROSE AND HORTICULTURAL SOCIETY announces that the annual Exhibition will be held on the 29th of June of the present year, when liberal prizes will be offered in sixty-six classes for nurserymen, gardeners, amateurs, and cottagers. Thirteen classes are devoted to Roses, the prizes ranging in value from £4 to 3s. Miscellaneous plants, fruit, vegetables, and table decorations are also provided for, and a satisfactory display may be confidently expected to reward the efforts of the enthusiastic Hon. Secretary, Mr. Frank Burnside.

— M. F. BRASSAC of Toulouse has forwarded us a copy of his ANNUAIRE GÉNÉRAL D'HORTICULTURE. It contains a variety of general information, with articles upon horticultural subjects, mostly reprints from French and Belgian periodicals, and a long list of nurserymen, florists, and seed merchants throughout France, arranged alphabetically under their several departments.

— A CORRESPONDENT writing respecting the MARÉCHAL NIEL ROSE observes—"This Rose may be grown very successfully on its own roots. A little over four years since I planted a very small side shoot against the back wall of a Peach house, and two years afterwards we had fully five hundred blooms on the plant. Since then it has grown freely and flowered profusely, and at the present time it is looking as well as ever it did. It is often said this Rose is short-lived, but I do not know of any case where it has died prematurely on its own roots. In many instances I think it is too freely supplied with stimulants and then killed with hard pruning, neither of which are necessary to its well-being. Judicious thinning of the shoots is more likely to produce good results."

— THE annual display of CINERARIAS AT REDLEES, ISLE-WORTH, is always worth a visit, but this year Mr. James appears to have been even more than ordinarily successful in his culture

The flowers are of excellent form and large, but the colours are surprising, comprising a wide range of tints—some delicately soft, others rich and intense. Bright glowing pink, crimsons of many shades, magenta, and deep maroon, with some good purples and abundant intermediate tints, combine to form an array of colours such as could be scarcely excelled. In habit, too, some of the plants are very compact—a very desirable quality, with fine imposing heads of blooms. Several of the named varieties for which first-class certificates have been awarded fully maintain their character. At the time of our visit the most notable of these were Master Harold, bright crimson, and Mr. Little, the latter a peculiar but beautiful tricolor variety, from which Mr. James reasonably expects to obtain a very distinct strain. He also has some other handsome novelties, selections from his large stock of plants, that will probably be exhibited; one in particular we noticed with large, flat, and beautifully formed rich magenta flowers of great substance, which will undoubtedly receive some attention.

— RELATIVE to the career of the late Mr. ALEXANDER OF REDBRAES, whose death we announced last week, we extract the following particulars from a recent issue of the *Scotsman*—"The deceased was a native of Banffshire, but came as a young man to Edinburgh, where he has long been known as a highly respected citizen. For many years Mr. Alexander was senior partner of Dicksons & Co., said to be the oldest seed and nursery business in the city, and indeed one of the oldest of our trading firms. Before retiring from that connection he was, we understand, the oldest representative of the seed and nursery trade in Scotland. He was one of the few surviving founders of the Scottish Arboricultural Society, and for many years acted as Secretary and Treasurer. He also for some time served as Auditor of the Caledonian Horticultural Society. Gifted with a retentive memory, and claiming friends in every part of Scotland, Mr. Alexander gathered a large store of information on Scottish matters which rendered his conversation peculiarly interesting. He was a Director of several of our local companies, but owing to failing health he had for some time before his death retired to a large extent into private life. He was, we believe, the anonymous donor of the fund from which 'the Model ward' in the new Royal Infirmary was furnished, and he has left legacies to various local charities." He was seventy-six years of age at the time of his death, which occurred on the 12th inst., as we have already noted.

— A CORRESPONDENT states that the Spring Exhibition of the MANCHESTER ROYAL BOTANICAL AND HORTICULTURAL SOCIETY, which was held last week in the Town Hall, proved very satisfactory, an attractive display being provided. Orchids were particularly fine; such exhibitors as Mr. J. Broome of Didsbury, Mr. George Hardy of Timperley, Mr. W. Leach of Fallowfield, and Mr. W. Sparkes of Charlwood House, Huyton, Liverpool, staging some handsome specimens from their well-known collections. Other exhibitors were Mr. S. Schloss of Bowden and Mr. Schneider of Cromwell Range, Fallowfield, who contributed attractive collections of flowering and fine-foliage plants. Of nurserymen the principal exhibitors were Messrs. Cutbush and Son of Highgate and Mr. B. S. Williams of Upper Holloway, both firms receiving special awards for their groups. First-class certificates were awarded to Mr. J. Tomkins for *Primula The Queen*, and to Mr. B. S. Williams for *Primula sinensis alba magnifica*.

#### THE STRAWBERRY EVERLASTING (*ASTELMA EXIMIUM*).

SINCE the appearance of a note upon this plant in the *Journal* a few weeks ago we have had many inquiries respecting it, and requesting us to give an illustration showing the general charac-

ters of the plant. In compliance with the desire of these correspondents, and also because it may be of interest to other readers, we have had the accompanying woodcut (fig. 54), prepared from a small spray. It represents the flower heads and bracts of the full size, one of the lower heads being shown in a young state before the central flowers have faded. The attractiveness of the plant depends upon the rich crimson colour of the large elliptical bracts which form a close globular head, in some degree suggestive of Strawberries, and from that circumstance the popular name is derived. The leaves and stems are whitish-green in colour, and thickly clothed with a woolly pubescence.

In some London florists' windows, particularly in Covent Garden,

Fig. 54.—*Astelma eximium*.

these dried flower heads are occasionally seen, being employed similarly to other so-called "Everlasting Flowers." We have not seen a plant in cultivation in this country, though it is said to have been introduced about the close of the last century. The London supply is, we are informed, obtained solely from the Cape of Good Hope, where it is cultivated by some of the local growers.

#### CULTIVATION OF THE CYCLAMEN.

THE Cyclamen when well grown is one of the most useful greenhouse plants we have for winter and spring flowering. The most satisfactory way of obtaining a stock is by seed, and it is best to obtain this from a good firm, as you may depend on obtaining seed that will produce plants worth growing. Before sowing consider when you desire to have the plants in bloom, so that from twelve to fifteen months may be allowed them for growth. To obtain flowers in November and December sow the seed at the end of September or early in October; for January and February sow in November or December; for March, April, and May, sow in January or early in February. It is possible to have the plants in bloom at all seasons of the year, but they are chiefly desired during the autumn and winter.

The first operation is the preparation of the seed box or pan. Place at the bottom a layer of potsherds; then mix the compost, which should consist of three parts mellow fibrous loam and one part of peat, leaf soil, well-decayed cow manure, and silver sand in equal proportions. Place the rougher portions of the compost over the drainage and some finely sifted on the top. Press firmly, allowing an inch from the top of the pan; then sow the seed as evenly as possible, covering it with the fine soil,

watering it well. Place a square of glass on the pot, then remove it to a Cucumber house or propagating frame in which a temperature from 65° to 75° is maintained. If bottom heat can be given the seed will germinate more quickly than otherwise. With proper attention the seedlings will begin to appear in three weeks or a month, but some may be five or six weeks or even longer. The glass should not be removed till the plants touch it, then gradually raise it until it can be dispensed with. As soon as the seedlings have made corms the size of a small pea they should be pricked out into other pans prepared as before, only the soil employed may be rougher. They should be an inch apart each way in the pans. Again assign them a warm place near the glass, keep them there till they are well established, which will be in about two months. Then shift them into 3-inch pots separately, employing the same compost as before, return them to the house, and keep the soil moist. If green fly appear recourse must be had to fumigation or syringing. The plants will grow freely, and should receive their final shift before becoming root-bound. Pots 5 to 6 inches in diameter are suitable, placing a crock over the hole, then 2 inches in depth with broken bones, adding a small portion of Clay's fertiliser to the soil. Keep the corm just above the soil, which must be pressed firmly round it. Transfer them to a frame in an open situation, plunging the pots in coal ashes as near the glass as possible. Shade during the hottest part of the day, and close the frame early in the afternoon. The plants may remain there till the middle of September, then remove them to a greenhouse. If desired to bloom early place them in an intermediate house near the glass. While in bloom a dry atmosphere is necessary, or the colours will run. Mark the best, so that they may be grown into fine specimens the second year.

After flowering remove the plants to a frame from which the frost can be excluded, gradually lessen the supply of water until the leaves turn yellow and fall; then give the plants a rest for five or six weeks, after which they should be shaken out and repotted. The corms should rest on the surface of the soil, then place in the frame again, and the lights may be kept off except in wet weather for the first month until the new growth commences. The soil must at first be only moderately moist, afterwards increasing the supply of water in proportion to the progress of the plants, but until they are in full growth and well furnished with foliage the greatest care must be taken to guard against excessive watering. The reason I believe why so many fail in growing *Cyclamens* is because they allow them to receive a check in their early stages. Another cause of failure is placing them outside in the sun till the corms are dried, and then they will not start freely into growth again.—(Read by Mr. H. Slaney, Florist, Nether Edge, at a Meeting of the Sheffield Gardeners' Improvement Society.)

### THE MOTH ORCHIDS.

RICHNESS and diversity characterise the vegetation of most tropical insular climates, for in such positions exist the chief requirements of vegetable life—heat and moisture, the former being constantly present, but the latter usually most abundant at particular seasons, when the plants grow with extraordinary luxuriance and rapidity. Such a region is that of the Indian Archipelago or Malayia, including the islands of Borneo, Sumatra, Java, and the Philippine group, where a high temperature prevails, which is softened and rendered beneficial to plant life by the humidity arising from a tropical ocean and heavy periodical rains. In consequence of these favourable conditions plants are abundant and diversified, many of the large natural orders prevailing in the tropics being strongly represented. Numerous beautiful species have been found and introduced to this country, but undoubtedly many more remain to be discovered, for large tracts still exist that have not been thoroughly explored by collectors or botanists. From the Philippine Islands in particular we have received among many other plants some handsome Orchids; and though they are comparatively few, their beauty, especially in the case of one genus, would encourage the expectation that others may yet be found equal to, or perhaps surpassing, them in floral attractions. Several species of *Aerides*, *Dendrobium*, *Vanda*, and *Saccolabium* have been obtained thence and are greatly prized, but their charms fade in comparison with the aristocrats of the Orchid world, the lovely *Phalænopsids* or Moth Orchids, which have their home in those islands. Not only do they rank among the most beautiful of their immediate congeners, but in the whole range of flowering plants there are few that equal, and fewer still that in chaste elegance can be considered to surpass, the principal species of *Phalænopsis*. Their claims to attention are not rested upon brilliantly coloured flowers, for pure white and soft tints prevail; but it is the delicacy of these shades, the wax-like substance, elegant form, and durability of the flowers, with broad handsome

foliage and a graceful habit, which entitle them to such pre-eminence.

It is almost needless to say more in praise of the *Phalænopsids*, as they are so well known and so generally admired when in good condition. Unfortunately, however, this desirable result is not too frequently attained; and so it often happens that, accompanying the admiration, we frequently hear the difficulties attending their cultivation deplored as a grave defect—that is, of course, by those who have been unsuccessful with them. On the other hand, some growers' experience is quite the contrary to this, and with little more than ordinary care the best results are obtained—namely, healthy growth and abundant flowers. This is one of the peculiarities of the genus, and is not easily accounted for. I know an instance where two gardeners have charge of establishments a few hundred yards apart. Both are careful intelligent men with a good knowledge of Orchid culture; yet one has very satisfactory *Phalænopsids*, and the other can only keep them alive, though both collections are apparently treated in a very similar manner. Still, taking them generally, there are fewer failures with these Orchids now than there were a few years ago, for their requirements are becoming better known; and though the plants appear to display strange partialities for particular places, yet undoubtedly this is chiefly due to the grower's careful observation of little items in their culture that others might consider of no importance. The habitat of the *Phalænopsids* gives a good indication of their requirements, but when growing under artificial circumstances many facts have to be taken into consideration. A moderately high temperature is necessary in the first place, the house devoted to East Indian Orchids being suitable; but where a structure can be specially devoted to them it is more satisfactory, as the treatment can be regulated with greater precision. This advantage can only be enjoyed where the collections are unusually large and no expense is spared to obtain them in the best condition, as in some nurseries and a few gentlemen's gardens. Where the means and stock are more limited the plants must be grown with other Orchids, then needing a little additional care to ensure their success. They may be even grown in an ordinary plant stove; but though good results have been occasionally obtained in that way, it is not a course to be recommended where there is an Orchid house. However, in the absence of this convenience a few specimens may be tried in the stove if a suitable position be selected. Some have tried cool treatment for *Phalænopsids*, but not, as far as I have seen, with encouraging results: indeed it seems so opposed to the conditions under which they exist in their native haunts that success could scarcely be expected. At the same time the excessively high temperatures which some growers consider necessary, too often accompanied by a corresponding deficiency of moisture in the house, are more hurtful than otherwise. To ensure the health of the plants the temperature in which they are growing should not at any time of the year be allowed to fall below 60°; and from the present month on through the summer—the season of growth—the minimum day temperature should be 70°, allowing a rise above that to 85° with sun heat. The minimum night temperature for the same period may average 5° lower than the first-named, which will also be suitable for the autumn and winter treatment.

As to the method in which "Moth Orchids" are grown, there is little to suggest a preference for baskets, blocks, or pots, as in all they will succeed nearly equally well under judicious culture, but for small plants nothing is better than the shallow pots or small pans now employed in many nurseries, especially in Messrs. Veitch & Sons' at Chelsea. These suit the *Phalænopsids* as well as they do many other Orchids, and being neat in appearance, easily kept clean, and permitting the ready shifting of the plants when necessary, they have much to recommend them, as many gardeners have long ascertained. In the case of either baskets or pots thorough drainage is needful, for the plants being epiphytal are impatient of stagnant moisture at the roots; and further, during growth a very liberal supply of water is required, which renders careful attention to this matter of still greater importance. Clean potsherds must be used freely, the larger pieces at the bottom and the smaller on the surface, which for pots should be within an inch or two of the rim; over them place the compost, consisting of sphagnum moss, a few pieces of fibrous peat, potsherds, and nodules of charcoal, raising it 2 or 3 inches above the rim of the pot or edge of the basket in the centre. Upon this secure the plant, which for some time after the operation will need carefully shading and supplying with water. When established *Phalænopsids* require plenty of light, but cannot endure exposure to the sun, as the foliage is apt to become scorched, thereby both disfiguring and injuring the plant. A light material should be used for the blind, so that it may not cause too deep a shade, also placing the plants on the sunny side of the house if

they are arranged with others either on a shelf or suspended from the roof, where they will be exposed to all the light possible with regard only to avoiding the undesirable scorching already mentioned. Another important point is ventilation, for these Orchids need all the fresh air that can be safely admitted to the house without reducing the temperature too much, or exposing the plants to cold draughts. At least that is my experience, but I am aware that some advocate a comparatively limited ventilation at all times. In regard to the supply of water, it must be remem-

bered that the plants have no pseudo-bulbs to act as a storehouse of nutriment; that the leaves are large and thick, exposing a great foliar surface, from which moisture is constantly evaporating when the temperature is sufficiently high; and that the plants, though elevated on the branches of trees, are exposed to heavy rains during the period of growth in their native habitats. These considerations indicate that water must be given very freely when the plants are growing, and at other times regulating it according to the weather, never allowing them to suffer from an

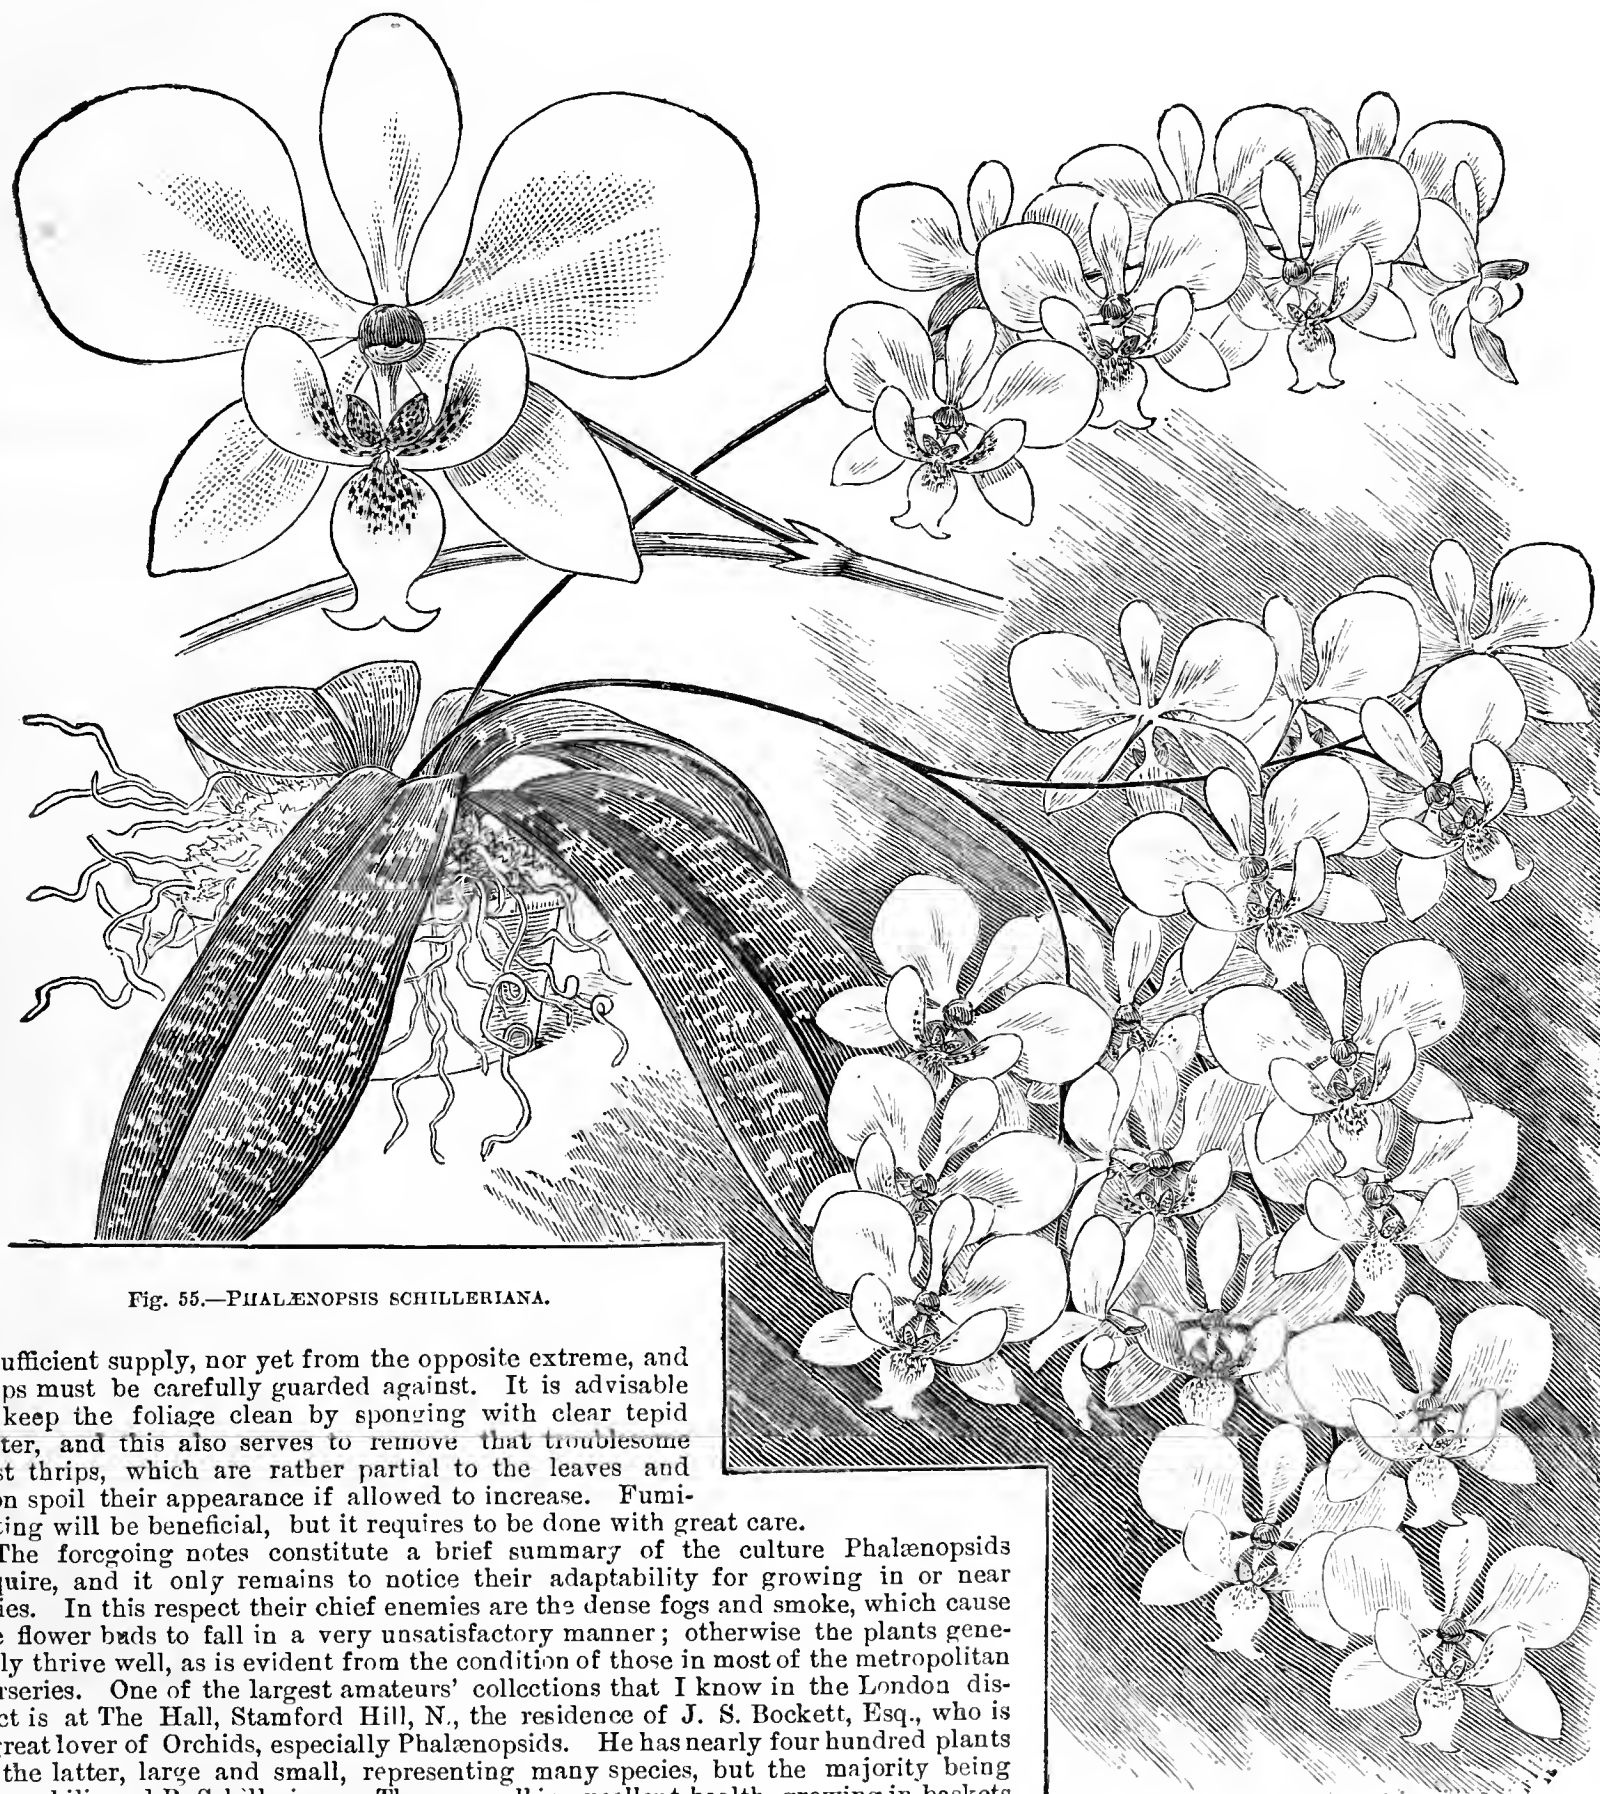

Fig. 55.—*PHALAENOPSIS SCHILLERIANA*.

insufficient supply, nor yet from the opposite extreme, and drips must be carefully guarded against. It is advisable to keep the foliage clean by sponging with clear tepid water, and this also serves to remove that troublesome pest thrips, which are rather partial to the leaves and soon spoil their appearance if allowed to increase. Fumigating will be beneficial, but it requires to be done with great care.

The foregoing notes constitute a brief summary of the culture *Phalaenopsis* require, and it only remains to notice their adaptability for growing in or near cities. In this respect their chief enemies are the dense fogs and smoke, which cause the flower buds to fall in a very unsatisfactory manner; otherwise the plants generally thrive well, as is evident from the condition of those in most of the metropolitan nurseries. One of the largest amateurs' collections that I know in the London district is at The Hall, Stamford Hill, N., the residence of J. S. Bockett, Esq., who is a great lover of Orchids, especially *Phalaenopsis*. He has nearly four hundred plants of the latter, large and small, representing many species, but the majority being *P. amabilis* and *P. Schilleriana*. These are all in excellent health, growing in baskets chiefly, but a few shallow pots are employed. From the vigorous healthy condition of the plants a visitor would scarcely think he was inspecting Orchids growing within five miles of the Mansion House. Possibly something is due to the elevated position; but the gardener, Mr. Ebbage, evidently well understands their treatment, and shows to the best possible advantage what good results may be obtained even in a great smoky city.

The genus is not a large one, the species in cultivation numbering about fifteen, with several varieties and supposed hybrids. Of these the following notes indicate the most attractive or interesting.

*Phalaenopsis amabilis*.—This was aptly named the "lovely" *Phalaenopsis*, and as the first brought to this country it was a good

representative of a beautiful genus. It has bright green, elliptical, broad, thick, flat leaves arranged very closely together in a two-ranked manner, so that there appears to be scarcely any stem. The inflorescence is a raceme, bearing numerous flowers. The sepals and petals are white, the latter larger and more rounded than the former; the lip is three-lobed, white, frequently marked with a few streaks of crimson, orange, and yellow. The flowers are produced during the winter and spring, and last upon the plant for months in good condition; in fact, there are few even among Orchids which retain their flowers so long as the *Phalænopsis*. The first plants which were received alive in England were those sent from Manilla to Messrs. Rolisson at Tooting by Mr. Hugh Cuming, who travelled so much in the Philippine Islands, and made extensive collections both of plants and the beautiful shells to be found there. That was in 1837, and soon after the plants flowered and were figured in several works during the three or four following years. In 1844 Mr. Robert Fortune visited the island of Luzon, and obtained specimens of this Orchid, particularly one, which he describes as "a plant of extraordinary size, having ten or twelve branching flowerstalks and upwards of a hundred flowers." This handsome specimen was purchased of some natives for the extremely moderate price of a dollar. It reached England alive, and was grown in the Royal Horticultural Society's gardens for some time. Since then large numbers have been imported, and the species is now well known to all Orchid growers. The price is now moderate compared with some Orchids, and plants can be purchased for a less number of shillings than they could for pounds some years ago. In connection with the value of this plant it is related that when the Duke of Devonshire first saw a specimen flowering in Messrs. Rolisson's nursery soon after its introduction he admired it so much that he determined to obtain it at any price. The possessors were reluctant to part with it, but the Duke gave them a blank cheque to fill in as they pleased, and they then fixed their price at £100, which might almost be considered moderate under the circumstances.

*P. Schilleriana*.—The most beautiful *Phalænopsis* yet known, for not only are the flowers uncommonly handsome but the foliage is also highly attractive, thus rendering the plant pleasing whether flowering or not. It can indeed scarcely be surpassed in the whole of the great Orchid family—a sufficient indication of its merits to those who do not know it, but they are extremely few at least among Orchid growers, for although it has only been in cultivation about twenty years it is now well and widely known. The leaves are arranged in a similar manner to *P. amabilis*, but they are much longer and broader, marbled or mottled with light green on a rich green ground. The peduncle is frequently a yard in length, branched and on very fine specimens has been known to bear as many as one hundred flowers. These have rounded petals and narrower sepals, all of a fine rosy colour, the intensity of which varies considerably in different plants; the lip is three-lobed as in *P. amabilis*, the lateral lobes rose-coloured, the central white with yellow protuberances at the base, the colour being bluish. English growers cannot claim the honour of having introduced this species, for it was first obtained in 1858 by Consul Schiller of Hamburg from Manilla, where it grows at a slightly higher elevation than *P. amabilis*. The plant flowered two years after, and was then described by Professor Reichenbach, and named in honour of its introducer. Specimens were soon forwarded to England, and early in 1862 Mr. Robert Warner of Broomfield had a plant in flower. Mr. B. S. Williams also flowered one about the same time, and great attention was attracted to the beauty of the species, leading to the importation of as large quantities as could be obtained.

The woodcut (fig. 55) was prepared from one of the plants in Messrs. Veitch's Nursery, Chelsea, which recently made the magnificent display described on page 113. About eighteen hundred flowers were open at one time, and the effect produced by such an immense number will long be remembered by all who saw them. They were mostly growing in the small pans as shown in the engraving, and though the plants had only been imported about a year they were in admirable health, the foliage being beautifully mottled. The figure represents the plant very much reduced, but the single flower is given full size, thus showing its form and the proportionate size of the plant.—L. CASTLE.

(To be continued.)

#### EARLY ROSES.

LAST November we bought a number of Roses for planting in the open air, but potted a dozen of them. For some time after that they were in a cold frame, and early in January they were placed in gentle heat, which caused them to start into growth, and most commenced flowering early in March, bearing fine buds and blooms.

As it is always convenient to know what varieties to grow, I give a list in the order of merit—Innocente Pirola, Madame Alexandra Bernaix, Belle Lyonnaise, Madame Etienne Levet, Madame Willermoz, Madame Falcot, Maréchal Niel, Perle des Jardins, Souvenir de Paul Neyron, Marie Van Houtte, Duchess of Edinburgh, and Céline Forestier. The first named (Innocente Pirola), is a new Rose and one of the best for culture in pots. In colour it is between Souvenir de Malmaison and Gloire de Dijon. The blooms are more pointed than those of the latter, and more acceptable, I think, in every way. It is very free in growth, and promises to be quite an exception to the majority of new Roses in merit. The second (Madame Alexandra Bernaix) is also a very fine Rose, the blooms being large and showy pink in colour. Marie Van Houtte and Duchess of Edinburgh have not done well; and Céline Forestier has been worse still, as it has only made some long shoots with no signs of bloom on one of them. We had a black mark placed against this Rose before. As planted out in a conservatory it has grown vigorously, but the blooms have been few, as all last summer we had not half a dozen clusters from it. Niphetos is not amongst our twelve, as we did not grow it in a pot, but had it been amongst those named above it would have been near the top of the list, as it is a grand indoor Rose at any season and under all modes of culture.—J. MUIR.

#### REVIEWS OF BOOKS.

*Practical Gardener*. James Carter & Co., 237, High Holborn, London.

GUIDES to gardening, from "Loudon's Encyclopædia" and "Thompson's Gardener's Assistant" to those valuable little "Manuals for the Many" published at the Journal office, are now so numerous and so comprehensive in scope as would seem to embrace every possible want of all classes of the gardening community. In Messrs. Carters' "Practical Gardener," which is modestly introduced "to supply reliable information to the amateur in a popular form," we have a work so thoroughly practical, so cheap, and so novel, that we greet its advent heartily, and commend it to the notice of all gardeners and amateurs, for many a pithy hint may be found in its pages on the culture of popular fruits, vegetables, and flowers.

A leading position is given to calendars, the first being devoted to vegetables by Mr. G. T. Miles, who gives excellent advice about vegetable culture and successional cropping, with a useful enumeration of varieties, but his sentences are somewhat involved, occasionally so much as to render his meaning obscure and to mar the effect of his otherwise valuable teaching. In "Flower Gardens and Pleasure Grounds," by Mr. T. Comber, we have concise and timely instructions for each month's work, and equally concise reasons given for most of it. Very forcible and valuable hints are given about watering, a matter to which by far too little attention is given. Many a failure might be traced to carelessness in this simple matter. Mr. T. Baines introduces his calendar of plant culture in the conservatory, greenhouse, &c., with brief notes on soil, potting, water, heat, light, air, and shade as the most important factors to success in this department. The Monthly Notes, though somewhat lengthy, are all to the purpose, embodying clear cultural directions, hints as to ventilation, the destruction of insect pests, propagation and culture of young stock for a successional supply, syringing, the value of fertilisers, and importance of cleanliness. "A Year's Work Under Glass," by Mr. J. Sheppard, is principally devoted to fruit culture, and is evidently written by an able practical man, some of whose sentences would, however, be none the worse for a somewhat more stringent application of editorial polish. "The Fruit Garden," by Mr. A. Bridgman, contains a useful list of sorts; but I cannot agree with him in his recommendation of horizontal training, which is quite superseded by the palmette verrier; and I regret to find no mention of that most useful of all forms, especially to amateurs—the diagonal cordon. Papers of considerable value on special subjects have been contributed by some of the best cultivators and writers whose names have been published in your advertising columns, and at the end of the volume is a useful chapter for amateurs on "Suburban Gardening." All who possess the book will, I think, agree with me that it is an excellent shilling's worth.—EDWARD LUCKHURST.

*On the Art of Gardening*. By Mrs. FRANCIS FOSTER. London: W. Satchell & Co.

THIS little work contains some pleasant reading upon the history and associations of gardening, with many poetical quotations and classical allusions, but is scarcely calculated to be of any great assistance to a gardener either in the theory or practice of his art. The volume, however, contains some hints that may

prove useful to amateurs. In an appendix some directions are given for forming and planting flower borders, and there sundry errors in the spelling of plant names occur. For instance, "Lithospermum" is repeated many times, while such singularities in nomenclature as *Camp Glomerata*, and *Yellow gagea*, are noticeable. The English and botanical names also appear to be given indiscriminately, so that some of the lists are strangely mixed. The garden of the writer has evidently been a source of pleasure to her, and her object appears to be the commendable one of making other gardens pleasant too.

*Our Kitchen Garden.* By TOM JERROLD. London: Chatto and Windus.

A WELL-PRINTED and neatly bound volume devoted to the culture and cooking of vegetables, the culinary recipes and particulars constituting the chief feature of the book. An account of the principal vegetables is given, Parsley being, however, strangely omitted, comprising brief historical notes, and an outline of culture, and then the various modes in which they may be prepared for the table. The author strongly advocates a diminution in the consumption of animal food, with a corresponding increase in the employment of vegetables.

*The Fields of Great Britain.* By HUGH CLEMENTS. London: Crosby Lockwood & Co.

THIS, as the title page states, is "a text book of agriculture for elementary and advanced students," and appears to have been carefully prepared in regard to the range of subjects treated upon and the accuracy of the facts given, but necessarily in an elementary manner. It contains particulars of the chemical composition of soils, with chapters devoted to the chief operations of the farm, and explanations of the principles upon which they are founded. It is neatly bound and printed, and will prove serviceable to those who are entering on the study of agriculture with a view to passing the Science and Art Examinations in that subject.

*The School Garden.* By T. WILKINSON. Harrow: W. J. Overhead, "Gazette" Office, High Street.

THOUGH only a modest pamphlet of twelve pages, this little production contains some valuable hints and suggestions upon extending the knowledge of gardening and agriculture among the masses. The necessity for this extension, the writer argues, is evident from the enormous amount annually paid by this country for imports of agricultural produce, when there are "hundreds of thousands of acres of good land entirely out of cultivation—absolutely waste." He then proceeds to state his scheme for effecting some improvement in this unsatisfactory state of affairs, by the practical teaching of horticulture in schools, to which plots of ground should be attached, as in Switzerland and some other countries. If the scheme could be put in practice it would unquestionably prove advantageous, and we therefore commend the pamphlet to the consideration of those interested in the subject of which it treats.

#### TEA ROSES.

I HAVE great pleasure in answering "WYLD SAVAGE'S" challenge, especially as it gives me an opportunity of bearing testimony to the beauty of his Tea and Noisette exhibits a few years ago. His enduring fondness for these most exquisite of all Roses in well-nigh every article he writes speaks for itself.

My friend deprecates prizes being offered for so many varieties of Teas and Noisettes as twenty-four and eighteen. Thus far I quite go with him. I should say every experienced rosarian would likewise. But on the main point of his article, Whether twenty-four good Teas and Noisettes could be named, nearly half of which would not be out of bloom by the beginning of July, I answer, Most certainly they can; and, what is more, I can supplement that number with almost as many again, which, though not so distinct and certain, can when wanted be advantageously used to make up a collection.

The great secret I hold to be, Never grow Tea and Noisette Roses where climatic or other conditions are unfavourable to their health and luxuriance. The difficulties and expense under such circumstances attending their culture is so enormous, and the degree of success ever attained so slight, that the game is not worth the candle. On the contrary, where climate, soil, and neighbourhood are found to be suitable no class of Roses is easier to grow; for when once established, fine exhibition blooms may often be cut from old-established plants—aye, worthy of the famous Colchester, Salisbury, Maresfield, and Torquay nurseries.

The same remarks hold good about many irrepressible rosarians, who vex their lives out year after year by uselessly trying to grow the strongest H.P. Roses in the immediate suburbs of manufacturing towns. I never could understand such infatuation. The Rose of course reigns supreme among flowers, but a badly grown Rose has the same depressing effect upon me as the sight of a deformed or sickly child; and when such hardy, varied, and lovely flowers can be grown—and perhaps grown in all the greater perfection from the presence of carbon in the air—as the Auricula in spring, the Carnation and Picotee in summer (rivals of the Rose at least in scent), and the Chrysanthemum in autumn, even up to winter's storms and frost, it is unaccountable how much loving care is wasted on the Rose only to end in certain disappointment.

I must ask pardon for this digression, for the lines of "WYLD SAVAGE," I am well aware, have fallen in quite sylvan scenes until very lately; yet I cannot understand in the few varieties he mentions of Teas and Noisettes how such universal favourites as *Tea Marie Van Houtte* and *Noisette Madame Caroline Kuster* were left out. Surely so critical an observer must often have noticed them as the brightest gems in Mr. Baker's great collections.

It is very noticeable in Teas and Noisettes, more so than in H.P.'s, that some varieties thrive vigorously in certain districts, while in others they are poor growers, shy bloomers, or unshapely in flower. I can generally grow *Noisette America* as large as *Souvenir de la Malmaison* without that Bourbon's flatness and coarseness. With me also *Tea Comtesse de Nadaillac* grows so different in shape, size, and hardiness, and of so extraordinary a colour under glass and out of doors, that when seen exhibited elsewhere it is quite a different flower. "WYLD SAVAGE," like that excellent rosarian Mr. Charles Turner, compares *Madame Bravy* (syn. *Madame Sertot*) with *Alba Rosea*, a fact which, if correct, goes far to prove the truth of my foregoing remarks.

As regards *Cheshunt Hybrid*, if shown in full bud, and as this hardy useful Rose is seen in spring or early summer of a glossy soft pink colour, the most fastidious could not object to its presence in any collection of Teas and Noisettes. As it is generally shown later on in the season—globular in shape, and of a dingy colour, the Rose is wholly out of place; but so under similar circumstances is *Maréchal Niel*.

The only remark I would make about the *Stapleford Roses* is, that time only makes them more unlike their catalogue descriptions, and less worthy of a place among such pure-blooded Teas and Noisettes as I now subjoin.

*List of Twenty-four Teas.*—*Alba Rosea*, *Anna Ollivier*, *Belle Lyonnaise*, *Catherine Mermet*, *Devonensis* or *Climbing Devonensis*, *Comtesse de Nadaillac*, *Comtesse Riza du Parc*, *Jean Ducher*, *Madame Berard*, *Madame Bravy*, *Madame Camille*, *Madame Céline Noirey*, *Madame Hippolyte Jamain*, *Madame Margottin*, *Madame Welche*, *Marie Guillot*, *Marie Van Houtte*, *Niphotos*, *Monsieur Furtado*, *Perle des Jardins*, *Souvenir d'Elise*, *Souvenir de Paul Neyron*, *Souvenir d'un Ami*, *Rubens*; and *Noisettes*—*America*, *Céline Forestier*, *Cloth of Gold*, *Lamarque*, *Madame Caroline Kuster*, *Maréchal Niel*, *Triomphe de Rennes*; supplemented by the following *Teas*—*Souvenir de M. Pernet*, *Mdlle. Innocente Pirola*, *La Boule d'Or*, *Eugène Desgaches*, *Elise Sauvage*, *Adam*, and *Madame Lambard*.—HEREFORDSHIRE INCUMBENT.

#### KITCHEN GARDEN.

A PART of the plantation of Horseradish should be lifted annually so as to have a good supply of this useful root, which should have more attention than is usual in private gardens. It can be lifted by trenching the ground and removing all small pieces of roots, selecting those fit for use, which may be laid in on a north border, reserving the thin pieces 15 inches or more in length for transplanting. The ground should be deeply trenched and have a liberal dressing of manure or decayed vegetable matter, the latter being perhaps the most suitable; when this is done plant the roots in rows 18 inches asunder, and about 9 inches apart. Ground intended for *Seakale*, also for fresh plantations of *Rhubarb* and *Globe Artichokes*, should be prepared at once by manuring and trenching. *Globe Artichokes* have been much injured by the severe weather. Do not remove the ashes or other protective material from the collars, as severe weather would

seriously injure the plants. If not already done preparation should be made for planting Asparagus by having the ground well manured and trenched, giving preference to ground already well enriched and of a good depth of rather light loam; if heavy, a good proportion of sand and old potting material should be mixed with it. Planting may be performed at once, but is best done when growth is commencing, selecting two-year-old plants. Remove the soil entirely a foot wide and 3 inches deep, so that the roots can be laid out evenly, covering with fine soil. If the roots are to be taken up for forcing the plants may be placed 18 inches apart and 2 feet distance between the rows, omitting every third row, whilst for permanent plantations the rows may be 3 feet and the plants 2 feet apart. Planting early Potatoes should be proceeded with without delay. Strawberry plantations must be examined and all weeds forked out, pointing the spaces between the plants lightly, and not so deeply as to disturb the roots. Where it is intended to make new plantations this spring the ground should be prepared by a dressing of manure and by trenching. If good well-rooted runners of last year are at command defer planting until growth takes place, lifting with a good ball of earth to each, firming the soil well about them, and giving a good watering if the weather be dry. Plants that have been layered in small pots are also suitable.

*Forcing Department.*—Shift Tomatoes into larger pots when they need it; 8-inch pots are sufficiently large for early fruiting, and ample to obtain strong plants for prepared borders or pots. Pot firmly, employing turfy loam with about a fourth of old manure. Train with one stem, removing all laterals, and have the plants near the glass to encourage sturdy growth. Make a sowing between now and the end of the month to raise plants for cultivation in cool houses, pits, and training to the walls outside. Ventilate frames freely on all favourable occasions, especially those containing plants raised in heat for outside planting. Potatoes advanced for taking up should be kept rather dry to improve their quality. A sowing of French Beans made now in a pit will come in in advance of those in the open. Continue to make sowings of these in pots or pits where there is sufficient heat to maintain the succession.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—Tying and regulating the shoots must have strict attention, avoiding overcrowding them or tying too tightly. Any very strong shoots may be stopped so as to equalise the growth. In the earliest house the stoning process will soon be completed, when it will be necessary to regulate the crop, reducing it to one fruit to each square foot of trellis covered by the trees. After the stoning is over the inside border must be well supplied with tepid liquid manure, and the surface mulched with about 2 inches of short manure, keeping it well moistened, syringing the trees twice a day in bright weather, but only once when the weather is dull. The temperature after stoning may be increased to 65° or 70° at night and 70° to 75° in the daytime, with an advance of 10° to 15° with sun heat. In the succession houses thinning the fruit must be attended to where too thickly set. Disbudding also will need early and repeated care, attending to tying-in the young shoots as they advance, being careful to regulate them so as not to be too crowded. Fertilisation of the blossoms in later houses should be attended to unless bees frequent the trees, when they will perform this work better than any artificial treatment.

*Figs.*—The earliest Figs will be swelling rapidly, and careful attention must be given in supplying water, especially to trees in pots, and if the pots are well drained there is little danger of an excessive supply. Continue 60° to 65° as the night temperature, and 10° more by day, but with sunless weather a few degrees less will be more beneficial to the trees. When the weather is favourable abundant ventilation will be necessary. Syringe twice a day, proportioning the moisture in the house in accordance with the increased light and sunshine. Fig trees in houses will be making rapid progress, hence the necessity of frequent attention to stopping and thinning the shoots. Attention must be given early to this, and the stopping of the shoots attended to as soon as the fourth or fifth joint is visible. Do not hasten later houses on too rapidly, but maintain a moderate degree of heat and moisture, with a liberal supply of air when the state of the weather permits, so as to secure sturdy short-jointed wood.

#### ORCHARD HOUSE.

Apricot trees in most localities in these structures are now flowering, and will require abundance of air whenever the state of the weather will admit; and should dull damp weather set in during the time the trees are in flower it is advisable to facilitate the setting by the use of a camel's-hair brush, which should be well filled with pollen from the anthers repeatedly and placed upon the stigmas. This, however, is not necessary when the air is dry, as the shaking of the trees sharply when the air is still will distribute the pollen effectually, or wind will effect the same purpose. When the nights are cold, as is usual after bright days, it is advisable to close the ventilators somewhat early in the afternoon, so as to retain as much as possible of the sun's heat as will prevent an injurious depression during the night. Syringing the trees must be discontinued until the frost is fairly set, when it should be resorted to in order to keep down insects, morning and evening, omitting the afternoon syringing when there are indications of frost or a low temperature at night. Water must be afforded trees in pots plentifully, also trees planted out. Allowing the soil in which fruit trees are growing to become too dry at any time during growth is very injurious, and should be carefully guarded against.

#### FLOWER GARDEN.

Operations in this department have been retarded by the wintry weather, and unless alterations are pushed forward vigorously there will be difficulty in having Box edgings and transplanted trees established before dry weather. Where large breadths of lawn have to be laid down measures should at once be taken to have it properly prepared and levelled. Before sowing the seed the surface must have a good tilth, and be firm so as not to admit any after-settling. The margin should be laid with turf 9 inches to a foot wide. Complete as soon as possible the planting of deciduous trees and shrubs. Press forward the pruning and training of Roses and other trellis plants, seeing that the shoots are not overcrowded, and laying in the strongest and best ripened. Protection afforded the tender wall plants and Tea Roses may now be removed, cutting out the weak branches of the latter, leaving only the strongest and best situated, shortening back only to well-ripened wood. Prune the Hybrid Perpetual Roses, thinning out the weak and old wood, shortening back the healthy wood more or less according to its strength. The surface of the beds should be pointed over, and be well mulched with short manure, especially where the soil is light. Many Roses do well on their own roots. Cuttings of Roses that have been forced and have the wood tolerably firm strike freely in brisk moist heat, the cuttings being inserted as the plants cease blooming. Pruning most evergreen shrubs may now be safely performed. Lawns will require well rolling, also walks. Any patchy or mossy places on lawns should have the surface well stirred with a rake, covered with fine sifted soil, and sown with grass seeds, lightly raking them in, and well rolled. Mossy lawns and where the grass is not sufficiently free in growth should be dressed with soot and wood ashes, applying the dressing at the rate of a peck per rod at once.

#### PLANT HOUSES.

*Stove.*—Increased length of day should be accompanied with more heat. The temperature now should be 65° to 70° at night and 70° to 75° by day, advancing to 80° and 85° with sun heat. Ventilate carefully, not allowing cold air to be admitted by the side lights directly on the tender foliage, but a little ventilation at the lower part of the stage may be allowed in the hottest part of the day. A more humid atmosphere will be necessary, which should be secured by damping available surfaces in the morning and syringing the plants in the afternoon. *Æchmeas*, *Billbergias*, *Gesneras*, *Tillandsias*, &c., should have a light position so as to insure their free flowering. *Hoyas*, such as *H. imperialis*, should be grown where they will not receive a great amount of atmospheric moisture, or the flowers will fall before opening. Cuttings of *Euphorbia jacquiniæflora* for early flowering may now be inserted, selecting those 4 to 6 inches long, taking them off with a heel; insert in sandy soil, and place in bottom heat. *Poinsettias* should be kept dry for a time after flowering, but not so as to cause the wood to shrivel. *Centropogons* also should be given a season of rest and have the flowering shoots cut back a little, and

when growth is pushing out back to within a couple of eyes of the base. Epiphyllums that have flowered should be potted. They succeed in turfy loam with a little well-decayed manure, and should not be overpotted; grafted plants do not need much root space. When it is desired to increase the stock of Allamandas, Bougainvilleas, Clerodendrons, and other quick-growing plants, cuttings can be taken of the shoots when 6 or 7 inches long with a heel, and inserted in small pots of light sandy soil in a close moist heat. Croton cuttings 8 to 10 inches long now inserted will strike freely in brisk moist heat. The tops of any tall Dracænas should also be taken off, potted, and treated similarly. The old stems laid in open material and kept moist will produce shoots with roots freely, and when sufficiently large should be detached and potted. Cuttings of Aphelandras, Gardenias, Ixoras, Rondeletias, and similar plants taken off with a heel, being careful not to injure the bark, and inserted in sandy soil, will strike better now than later in the season, and if kept growing make useful plants by autumn. Amaryllises are producing their flower scapes, and should be assisted with tepid weak liquid manure. Gloxinias started some time ago may now be shifted into larger pots, and be placed near the glass to keep them sturdy. Pot another batch, and start in gentle heat.

## THE BEE-KEEPER.

### DISCUSSION ON MR. LYON'S PAPER AT THE CONVERSAZIONE OF THE BRITISH BEE-KEEPERS' ASSOCIATION.

EXPERIMENTS ON HIVE SIDES, BY MR. CHESHIRE.

BISHOP TOZER, occupying the chair, said he must express his thanks to Mr. Lyon for the wonderfully clear way in which he had put his theory before them. The thing they had to consider was how they could best photograph what they had heard and bring it before the intelligence of the labouring classes. He invited Mr. Cheshire to begin the discussion.

Mr. Cheshire said he thought Mr. Lyon had worked out his hive with the materials to which he had limited himself with a good deal of ingenuity, and that nothing seemed to remain to be suggested which would not add to the cost. If he said anything which would tend to show that the hive under discussion was not perfect he must not be understood to be detracting from the value of the good work Mr. Lyon had in hand; yet with the expenditure of very little more money the hive might be made much more serviceable, especially for winter, than in its present form; but before explaining how he would refer to one or two points occurring incidentally in the paper read. Mr. Lyon had spoken disparagingly of distance tacks, but he ventured to predict that they would hold their own very much longer than the broad-shouldered frames, which were unconquerably inconvenient in several directions, always getting fixed, and only removeable by a wrench most irritating to the bees; while the more usual form of frame on a metal runner admitted of slipping backwards and forwards half a dozen at a time in the readiest manner. [Mr. Hooker.—These broad shoulders are always shrinking and swelling, and so are always either too tight or too loose.] The question also had been raised whether pitch used for waterproofing would be a success; but he could assure Mr. Lyon that the plan he had devised and first suggested in "Practical Bee-keeping" seven years before had been most serviceable to cottagers, as he had often been able to notice. It was only necessary to cover roughly with pitch the wooden article to be waterproofed and then spread paper over it. The outside of the paper was now pressed down with a heated flat iron. The running pitch settled into all cracks and soaked the paper, preventing the weather from afterwards affecting it, and preserving it for years. Mr. Cheshire said that the main objection he should make to Mr. Lyon's hive was the thinness of its walls. Nothing was really more essential than high non-conductivity; and many so-called cheap hives, failing here, had much to answer for [hear, hear]. He had lately had a correspondence with a gentleman of the sister island upon this very point; and the result had been a determination on his (Mr. Cheshire's) part to put the whole thing to the test of experiment, the results of which he now presented to the meeting. (Mr. Cheshire illustrated his remarks with a number of boxes of different makes.) He said, I have here a number of tin chambers, all capable of holding 12 ozs. of water. I placed these in the several boxes before us after filling them with water at 200°, and exposed them under equal conditions, noting carefully the times occupied in each case by the water in falling through a certain number of degrees of temperature. This very delicate thermometer was used, and the calculations were made according to Newton's law of cooling, which, applied to our purpose, is in effect that temperature changes in direct proportion to the difference between

the temperature of the body under experiment and the surrounding air. I found that if the non-conductivity of the single hive side of five-eighth-inch pine be represented by 1, that of the double side, as we have it in this second box, with an inch of dead air would be represented by 4. I now proceeded to compare this dead air space with the same space packed with chaff, and found that this in preventing loss of heat was twice and a half as effective as dead air, or in other words that its non-conductivity should be represented by 10. I had foreseen the superiority of the chaff to the air space, but was not prepared for so great a difference. It has been argued air is a better non-conductor than any solid substance, and therefore it is better than any form of packing; but the fallacy lies in this, that the so-called dead air is not dead but circulating. It rises against the inner skin of the hive and falls where it touches the outer, and so is ever acting as a distributor of heat. In the same way a man in bed might argue that the air is a better non-conductor than the bedclothes, therefore he would say I shall be warmer without them; but universal experience contradicts the supposition. The bedclothes are useful because they prevent the circulation of air, and that next the body, being warmed, is imprisoned instead of passing away for cold to take its place.

The advantage of a non-conductive packing being proved I now asked whether chaff was the best material at command for this purpose, and cork dust as used for packing Spanish Grapes at once occurred to me as a waste product to be had generally for the asking, and trying this I found that it was much more effective than chaff, giving me a non-conductivity of 14 instead of 10. I had now a hive side three and half times as good as the air space and double skin of wood, and which has for the cottager and amateur this great advantage, that while accurate carpentry is needed to secure dead (?) air, the cork packing makes the air practically dead, even if the wood joints be most defective in their fit. The cottager with very little trouble could convert the hive as shown by Mr. Lyon into a cork-packed one thus:—Having secured a second box so much larger than the one used for the hive body that the latter would go into it with a space of an inch or so between them, he would complete his hive but omit the alighting board; and now, putting the former into position, would make a little wooden bridge, which would act as a tunnel, permitting the bees to pass from the inner box through the outer one into the air. Cork dust would now be somewhat tightly packed between them and covered above by wooden slips, when the cottager would possess a hive superior for wintering to the most costly ones now in common use. The bottom would be a fixture, but this would be no disadvantage in such a hive as would then be. With hive sides made as described small lots of bees may be wintered with success almost incredible to those using thin hives only. A teacupful of bees placed on two frames in a twin hive 3 inches thick and chaff-packed has gone on well since the end of October till now, the queen breeding continually on the frame against the division board. Five other nuclei I have similarly wintered with no casualty. In thin hives the sides are too cold to permit the bees to touch them in hard weather, so that they are driven to remaining in the middle of their frames exposed on all sides, while they are often lost in detachments because they cannot get from comb to comb; but in these they winter by preference against the hive wall, and are thus only exposed on one side, while they close the frame ends for themselves, and can pass always freely from comb to comb without a possibility of getting separated from one another. The advantage may be seen at once by stating that a thin wall would pass as much heat through it in a week as a cork-packed one would in three months; and that if we take the heat of the cluster as 65° Fahr., a little calculation based upon Newton's law (which though lately proved not absolutely accurate for extreme temperatures is sufficiently so for such as those with which we have to do), we shall find that my hive side will be as bearable to the bees with an external temperature of 20° as that of 1-inch pine would be with the outside air at 59°. Mr. Cheshire added, I have not made any experiments in reference to straw. Of course the test apparatus must be made accurately to give data of any value, and this involves a good deal of cost, but notwithstanding I do not mean to leave the straw untried.

Mr. Cowan said, Of course their object was to teach cottagers to keep bees on the most improved system. He questioned very much whether they were really doing very much good in giving them a very cheap hive like this. The objection he had to the hive shown was the thinness of its sides, but of course it would be in a great measure got over if Mr. Cheshire's plan were adopted. He was very much interested in the manner Mr. Lyon manufactured those frames, but he was very much afraid the ingenuity displayed was more than the general cottager in England could be accredited with. If the Association desired to do good in this matter it would be well of them to have their frames made and supply them to cottagers at a cheap rate. Of course all had their crotchets; Mr. Cheshire had distance tacks, but he had nothing. Anyone who had practised a little would be able to do just as well without distance tacks. Another objection he had to shoulder frames was the propolisation. He did not object very much to the size of the frames, but he should like to see them much longer than they were in the specimen hive, the reason being that the queen bee was induced to spread out her brood on one frame in early spring much more rapidly than she would if she had to move from one frame to another; therefore he preferred the longer frames, and the depth might be a little less than those shown

by Mr. Lyon. Beyond these objections he had very little to say against the hive. The entrance to the specimen hive he noticed was only 3 inches and three-eighths of an inch in depth. In a hive of the same capacity he had 8-inch openings, and at times he found that hardly sufficient when he had raised the hive to increase the opening. He should be afraid so small an opening would suffocate the bees. [Mr. Cheshire.—My hives have 8-inch openings.] Mr. Cowan said now that he had disposed of Mr. Lyon's hive he should like to say a few words upon what Mr. Cheshire had been speaking about, and he was sure the Association's thanks were due to that gentleman for his experiments. For the last two years he had been making experiments with chaff hives. Although he has not carried his experiments to the extent Mr. Cheshire had, he had found bees winter infinitely better in chaff hives than they did in hives with dead airspace. He had reduced all his hives to six frames for wintering, and he had tried two frames only with perfect success. He had a hive of two frames, in which the queen had been breeding all through the winter. He did not think she had ceased at all, but of course there was only a small amount of brood. This hive had been fed with peaflour candy. The bees had had nothing to live upon but this all the winter, notwithstanding which they were no less in number than before. With regard to the snow, he found on the 18th January his hives were covered in snow to the depth of 6 feet. He had heard that many bee-keepers removed the snow, but he did not do so, and the bees did not suffer any inconvenience. His reason for adopting this course was that when in Russia he noticed the hives were sometimes covered to the depth of 8 or 9 feet, but the bees were never disturbed, and the losses were few. As soon as the late severe frost broke up he examined his hives, and was pleased to say that not one of them had suffered. So that chaff hives certainly had an advantage over other hives filled with dead air space.

The Rev. G. Raynor said his hives, occupying a very exposed position, were nearly filled with snow on the 18th January, but he succeeded in transferring them to other hives with very little loss. The hive shown by Mr. Lyon was just the kind of thing they should introduce to the cottager. In the course of Mr. Cheshire's remarks it occurred to him whether it was really advisable to keep bees so much warmer during the winter months, and whether it would not encourage breeding at a time when the queen required rest. The advanced American bee-keepers all appeared to approve of the chaff hives, but it had occurred to him whether the advantage was as great as would appear at first sight.

Mr. Baldwin asked if it would not be an improvement to Mr. Lyon's hive to have the floorboard protected in order to prevent the water drawing under. This could be done by making plinths. He had been amused with Mr. Lyon's ingenuity, but he believed it was pretty well conceded that distance racks were much better than the wide shoulders.

Mr. Cowan said, As to whether it was advisable to keep bees at a high temperature in winter, if the bee-keeper did not help them they would only have so much the more to do for themselves. The object of the bee-keeper should be to keep his stocks as quiet as possible, so that less food might be consumed. A cluster of bees should be kept at 65°. He only kept his queen bees two years; they were in full profit in the second year, after that he got rid of them. If the queen bee were kept breeding throughout the winter her breeding power was exhausted before the third season. Mr. Baldwin did not think there was sufficient ventilation in the top of Mr. Lyon's hive. Mr. Cheshire argued that there was no fear of bees becoming too warm. They regulated their temperature by their breathing through their spiracles. The more heat they had to provide the more they were exhausted. They became quiescent if little heat was demanded of them; but intense cold, if they were imperfectly defended, caused them heavy exertion and great exhaustion. Hibernation would explain the matter. Bats in cluster during the winter in ordinary low temperatures breathe but very little, and consume the store of material within them but very slowly, and as the temperature falls they become more and more dormant up to a certain point, but this being passed dormancy would soon lead to death, and then the increased cold renders them more active. The breathing is quickened and the store within more quickly oxidised in order that temperature sufficient to maintain vitality may be preserved. In like manner with bees, apart from the exhaustion incident to the feeding of brood, the measure of heat necessary to be produced is the measure of wear, and the measure of consumption of store likewise. Mr. Martin said that he as a cottager had made and used chaff hives with considerable success.

Mr. Lyon replied, stating that he thought his hive could be provided with most of the matters suggested without difficulty. The usual vote of thanks terminated the proceedings.

### THE INTRODUCTION OF BEE CULTURE INTO THE ISLAND OF CEYLON.

[From the "Ceylon Observer," January 26th, 1881, communicated by ALFRED NEIGHBOUR.]

DURING a short stay in Ceylon I have made diligent inquiry in this part of the island regarding the honey bee found here, and have also endeavoured to learn whether any bees were kept in hives or not. In the vicinity of Galle I found no bees except

the wild bees of the Jungle. When asked why they did not keep bees, the natives invariably replied, "It is too much trouble." But I do not think they know how to manage these insects. I was told that in the interior bees are kept in earthen pots or jugs, a statement which was, however, contradicted by most persons with whom I talked.

There is no reason why a region so productive as the island of Ceylon, and so well adapted in every way to the raising of bees, should not yield annually honey and wax to the value of many thousand pounds sterling. In the United States of America this industry is still in its infancy, improved methods in bee culture not having obtained in all parts and the "field" not being one-tenth occupied; yet the annual honey and wax product of that country exceeds one million pounds sterling, and tons of pure nectar are yearly shipped to Europe, much of it being sold in English markets at 4½d. to 6d. per lb. One weekly publication and six monthlies are devoted to bee culture in America. Those familiar with the condition of agriculture in Great Britain and Ireland admit that the industry is sadly neglected, yet moveable-comb bee hives with improved methods are gaining ground, and England has one journal wholly and another partly devoted to the interests of bee-culturists.

About a year ago I came to the island of Cyprus mainly for the purpose of rearing and sending to European countries and to America queen bees of the highly valuable race found on that island. Among the Greek and Turkish peasants of Cyprus I found a system of bee-keeping which, though far behind the modern improved methods, is still superior to the cruel plan yet followed largely in many of the countries of Europe, notably in France and even in England—namely, the barbarous practice of brimstoning the bees to obtain their honey. The native bee-owners in Cyprus place the bees in clay cylinders, some of which are baked, others sun-dried, and these are then piled up and covered with a roof, or embedded in the walls of the houses. The cylinders, which are about a yard long and 8 or 10 inches in diameter, have their ends closed by stone disks plastered in with clay, a small entrance hole being left the bees at the front end. When the time for taking the honey arrives the peasant bee-keeper removes the rear disk, and having smoked the bees from the rear combs cuts out a portion of the latter, leaving the bees, however, some combs of honey for their subsistence until the next gathering season arrives. According to the books of the collector of tithes the number of hives of bees kept in Cyprus in 1879 was 31,432, and the sale of honey and wax forms no inconsiderable item to the peasant owner of bees.

If that poor, barren, rocky island, Cyprus, successively robbed by various governments and rulers, and for more than three hundred years under Turkish misrule, could constantly derive benefit through the culture of bees, surely Ceylon under fostering Britain's care can show a result a hundredfold greater. That Cyprus in its flourishing days, before it was so nearly stripped of its forests, yielded much better results in this direction, is shown by the figures given me by the officer mentioned above, who stated that there formerly existed on the island 200,000 hives of bees. In the scattering of pollen from flower to flower, and consequent complete fertilisation of the blossoms, insuring a larger yield of fruit or seeds, the bees play no unimportant part. Here, then, is an industry which should go hand in hand with fruit-growing, Coffee-planting, Cotton-raising, &c., and should add to the wealth of Ceylon by putting into a marketable form the nectar which now "wastes its sweetness on the desert air."

The Dutch Government, seeing the advantages likely to accrue through the cultivation of bees in Java, sent to that possession several years ago a native of Holland, commissioning him to transport from Europe colonies of the Italian and Cyprian bees, and to superintend their introduction into that island. If this undertaking has not been successful it is only because the Government referred to was so unfortunate as to have selected for the work a man lacking the necessary practical experience and qualifications. The undertaking has, however, by no means been relinquished, and I feel safe in predicting that living colonies of the species *Apis mellifica* will soon be landed in Java, having myself brought safely as far as Ceylon seventeen colonies of Cyprian and Holy Land bees which are to be taken to that island.

For the island of Ceylon the rude method of keeping bees practised in Cyprus and the adjacent Mediterranean countries would be preferable to no bee culture at all, yet as wood is here abundant hollow logs might be sawed into suitable lengths, a board nailed over one end for a cover, and the hive thus formed placed upon its open end on a stand a few inches from the ground; an auger hole bored through the board cover would permit the bees to enter a box placed over it, and there deposit surplus honey. When filled at the end of the honey season the box can

be removed without disturbing the bees in the body part of the hive, or boxes of about 2000 inches capacity can be treated in the same manner. Hiving the bees simply consists in shaking the cluster from the tree upon which it has lodged into the box or into a basket, and then pouring it down before the hive. Most of the natives have little fear of bees; moreover, when bees are about to swarm it is their instinct to gorge themselves with honey, and when their honey sacs are thus filled they never sting unless pressed in the hand or under the clothing.

The simple methods indicated above are surely not beyond the comprehension of the natives of Ceylon; indeed, I believe an additional step might be taken at the outset, a step which in the long run would be found wise.

Frame hives, something essential to modern bee culture, might be introduced into some of the Government gardens, and would then find favour elsewhere. Notches in the upper edge of the hive would insure the placing of the frames at proper distances one from another, and the main advantages of the moveable-comb system would be gradually learned by practice in the handling the bees. To start this work the Government might manufacture and sell at cost simple moveable-comb hives, perhaps even stocked with bees, and for the present exempt the industry from taxation.

These are the ideas which suggest themselves to the mind of one whose stay in Ceylon must necessarily be very short, but who feels an interest in seeing a favourite pursuit receive the attention its importance demands.—(Signed) FRANK BENTON, of the State Agricultural College, Lansing, Michigan, U.S. America.

Colombo, January 25th, 1881.

P.S.—Mr. Benton's further contribution—entitled "A Journey to the Indies; The Bees of the Island of Ceylon"—will follow. He divides the paper into—the Trip down the Red Sea, Aden, across the Indian Ocean (all with reference to the welfare of the bees in his charge), the Island of Ceylon Bee-hunting, the Large Bees, the Honey Bees of Ceylon; a Description of the New Race—the Workers, the Queen, the Drones, Additional Observations.—A. N.

#### TRADE CATALOGUES RECEIVED.

Samuel Yates, 16 and 18, Old Millgate, Manchester.—*Catalogue of Vegetable and Flower Seeds.*

M. E. & E. Horley, Toddington, Beds.—*Illustrated Catalogue of Garden Structures.*

\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**Books** (James D. Ker).—Our manual on "Florists' Flowers" contains information on the properties and culture of Auriculas; it can be had by post in return for 4½d. in postage stamps sent to the publisher. Mr. Douglas's book on "Hardy Florists' Flowers" would be useful to you, but we do not know whether the edition is all sold or not; you can gain this information with particulars as to price by writing to the author at Loxford Hall, Ilford, Essex. (J. L. O.)—Mr. Iggulden's manual on the "Tomato" contains all the information you require. It can be had post free from this office for 1s. 1d.

**Address** (E. J. Hughes and J. D. K.).—Your letters have been forwarded to the gentleman whom you desired to have them.

**Watering Vallotas** (A. Boyle).—If the pots are very much crowded with roots, and the plants are in a sunny position during hot weather in summer, it is better to place the pots in saucers of water than to permit the foliage to flag. If you place the pots within larger during hot weather you will find the shade so afforded the roots very beneficial, and the soil will not dry nearly so rapidly as if the pots containing the roots were exposed to the sun.

**Vine Bleeding** (F. J.).—You adopted a good mode of arresting the flow of sap—namely, dressing with painters' knotting, and we are glad to learn it proved efficacious. The little sap that may escape now will do no harm, as the Vine will commence growing shortly and the bleeding will cease. You pruned the Vine quite correctly, and had you at the same time rubbed some lead paint on the fresh-made cuts in all probability there would have been no exudation of sap from the Vine now. The bleeding is a sign of good health rather than otherwise, but it occurs most with Vines that have not thoroughly ripened their wood.

**Grafting Espalier Trees** (Idem).—If the scions are inserted between the bark and the wood of the severed branches, which is a safe and simple mode of grafting such trees, and the one most frequently adopted, there will be no need for anything besides ligatures to keep the scions firm in their places. We have seen pins used without injury when softwooded plants have been grafted,

such as placing Epiphyllams on Pereskia stocks, but we have never seen the necessity of similar aids in grafting fruit trees.

**Purchasing Gladioli** (Idem).—As economy is a great consideration you cannot do better than write to a dealer in the corms and ask him to send you a stipulated number of the best varieties he can supply for the price that you name to him. If you select the varieties you will be charged a higher price because the stock of some of them may be low, while of others equally good there may be an abundance of corms. Unbloomed seedlings from a good source are sure to include some varieties of merit for garden decoration, and for this purpose we should not hesitate to plant them.

**Heating with Paraffin Oil** (J. B.).—While paraffin lamps are serviceable for excluding frost from frames and very small structures, they are not by any means equal to hot-water or even a good flue for heating greenhouses. The smoke from the lamps is injurious to flowers, and so also is the dry atmosphere that results from the lamps being overheated, as they not infrequently are during severe weather.

**Alternanthera paronychioides aurea** (G. C. W., Mass., U.S.A.).—This variety originated in Battersea Park. It is of the same habit of growth as the species, but the prevailing colour is reddish gold. It is very distinct, and is effective for carpet bedding. The stock we believe passed into the hands of Messrs. James Veitch and Sons, Chelsea, for distribution. A description of the bedding in the London parks appeared in our last volume, and notes of a similar character will no doubt appear during the present year. The specimens you sent were mere scraps of stems and leaves without flowers, and were further rendered almost unrecognisable by having been crushed in transit. However, from the few characters traceable we think 1 is *Lavandula dentata*, and 2, *Santolina Chamaecyparissus*. When you are writing again send better specimens to enable us to identify them with certainty.

**Growing Gloxinias for Greenhouse** (Amateur).—You may, with the assistance of a hotbed, grow these plants for greenhouse decoration. They should be placed in the hotbed not later than the beginning of April, better during this month, be continued there until the close of May or beginning of June, and then be placed in the lightest and warmest part of the house, keeping the sashes on that part closer than those elsewhere. The plants should be well supplied with water when in active growth and in full foliage. When coming into flower a slight shade from powerful sun is desirable.

**Crocus versicolor** (L. H., Yorkshire).—Your "small early treacle-coloured Crocus" which you had from Holland is probably the one that is sold under the above name. We know it well, and have grown it for some years. It is the most attractive before the flowers expand, as only the outside of the petals are of a dark reddish brown colour, the interior being chiefly yellow, the flowers opening almost flat, as shown in the figure. With us it is one of the earliest of the genus, and, although it is distinct and pretty does not produce such a rich display in borders as the leading garden varieties that are so extensively grown.

Fig. 56.—*Crocus versicolor*.

**Compost for Vine Border** (J. N.).—As you require to know how to make a "first-class Vine border," we will state how the Vine borders at Arkleton were made, and append the results achieved by Mr. Dickson, the gardener there. In the first place the borders rest on several feet of gravel, so that the important condition of perfect drainage is provided by Nature. The inside border is 14½ feet wide and 3½ feet deep; the outside border is of the same width and the same depth in front, and 2½ feet deep at the edge next the walk. The Vines are planted inside, and have free access to the outside border. The components of the soil are fibry loam of medium texture taken from an old sheep pasture, and to every twelve cartloads of turf were added two cartloads of old lime rubbish, one cartload of horse droppings, one cartload of charecoal, and 5 cwt. of inch bones. The turf was fresh from the field, mixed well with the other ingredients, and wheeled into the border without lying exposed. That may be taken as a first-rate recipe for a Vine border, judged at least by the following results, which are certainly "first-class." In the year 1869, at the Edinburgh International Exhibition, the first prize was awarded to Mr. Dickson for a bunch weighing 16½ lbs.; in 1870 the first-prize bunch at the Royal Caledonian Society's Show weighed 19 lbs. 5 ozs.; in 1871 the first-prize bunch at the same Society's Show weighed 18 lbs. 7 ozs.; in 1872 the first-prize bunch at Glasgow weighed 19½ lbs. 6 ozs.; in 1873 at Manchester the prize bunch weighed 16 lbs. 1 oz.; and in the same year another bunch at Glasgow weighed 16 lbs. 10 ozs.; then came the bunch produced in 1875, weighing (by the Judges) 25 lbs. 15 ozs. We do not advise you to make the border its full width now. A width of 4 feet will probably be sufficient the first year, the front being supported with a wall of turf. If the soil is in the right condition as to moisture—that is, moderately moist but not wet—you may press it down slightly as it is placed in position, and it will not afterwards settle to do any harm; in fact it will not settle at all if the work is rightly done, and we should not give the border "a good soaking a few days before planting." Making a border is only one element in Grape culture. If you would like fuller particulars of Mr. Dickson's practice you will find them recorded in Nos. 757 and 312 of the Journal, the issues of September 30th and October 7th, 1875. If you do not possess these numbers they can be had from the publisher, price 3½d. each.

**Protecting Fruit Trees** (Willesden).—The cheapest and best mode of fixing a temporary coping for protection is by iron brackets driven into the wall about 4½ inches, and projecting from the wall the full width of the copings, which should not be less than 11 inches, and better if 13 or 14 inches. If there are stone copings to the wall the brackets are best let into and leaded in them. The simplest plan of fixing the protection to the wall is by means of rings, there being a light iron rod fixed in front of the coping, and the material may, therefore be drawn aside like curtains. We know of no simpler plan; but a better plan is to have a roller fixed immediately under the coping, and the material tacked to that, which with a cord may be folded or rolled up and down like a greenhouse blind.

**Cutting Down Ferns** (F. O. M.).—Provided the old fronds of Maiden-hair and other Ferns are perfectly healthy there is no occasion for cutting them

down. Any of the older fronds that are showing signs of decay may be removed carefully, and so afford room for the young fronds to grow. By this plan you will obtain large plants in a less time than if you cut off all the old fronds annually; but if you prefer small and very fresh plants for any particular decorative purpose you may remove the old fronds as you propose. It is well, however, to remember that the young fronds of Ferns do not last half so long when cut and used in bouquets, &c., as the older and darker-coloured fronds do. Useful works on Ferns are "British Ferns," published at this office, price 3s. 9d., post free, and "Select Ferns and Lycopods," published at the Victoria and Paradise Nurseries, Holloway, London, price 5s. 6d., post free.

**Vines Unhealthy (Lonsdale).**—The Vine appears to have been cut down several times, and the sap vessels near the root are much contracted. The roots have made no growth: possibly they were either much dried during the summer or frozen during the winter. The top growth made is from the stored-up sap in the cane, and, the supply ceasing, withering of the foliage necessarily followed. The Vine made an attempt to live by producing roots from the stem, and if good soil had been placed round these and water given as needed it would eventually have recovered, but it is doubtful if it would have made a vigorous and fruitful Vine. We should not like to plant such a checked and starved example, and it would be far more satisfactory and in the end economical to purchase fresh young healthy canes for planting.

**List of Roses (A Subscriber).**—A moment's thought will satisfy you that the hardness of Roses depends greatly on the position and on the district in which they are grown, and until you name the district for which plants are required your letter cannot be satisfactorily answered.

**Names of Fruit (W. H. D.).**—Barcelona Pearmain. (H. M.).—1, Dume-low's Seedling; 2, Court Pendu Plat; 3, Bergamotte Esperen.

**Names of Plants (A Young Gardener).**—Andromeda floribunda.

**Bees Coming out on Snow (J. S. Cairnie).**—Had you removed the snow from the hive door at dusk and then shaded carefully we hardly think you would have experienced the loss of which you complain. The jar of a footfall near a hive at such times will often start a flight which it is difficult to restrain. The safest course, but perhaps an impossible one, would have been to have placed the hives before the snow had thawed from the mouth in a totally dark cellar until it had been safe for the bees to fly, and to have restored them to their proper stands late in the evening. The cause is clearly the long confinement to which the bees have been subjected, making them intensely anxious to be abroad. While they are in this condition stopping the doorway but increases the evil, as a risk is then run of losing the whole hive by suffocation, and at best very many die of mere exhaustion through continually worrying and hattering themselves against the closure. If you can secure absolute darkness and yet give sufficient ventilation you will extremely reduce if not altogether prevent the loss of which you complain.

**Feeding Bees by Day and Night—Feeding through the Quilt—Giving Foundation—Flour Cake (Goosequill).**—We have submitted your queries to Mr. Cheshire, who replies thus:—Commencing to feed a stock in early spring sets up considerable excitement, and if this be done during daylight the bees, not at the bottle, knowing that their companions have found booty, rush from the hive to scour the country in search of it. They thus exhaust themselves, and in addition often expose themselves to destructive cold and rain, and at the best get nothing. Stocks may thus through injudicious feeding be weakened more than helped. Either put on the hottle at night and feed continuously and very slowly (for in this way the excitement has nearly subsided by the morning), or give only so much each night as will be taken before full daylight. There has been an arrangement exhibited for feeding through the quilt and chaff box also if desired. It consisted of a small tin can with a central hole in the bottom into which a short brass pipe was soldered. This was provided with a closely-fitting cotton wick. This is placed in position filled with syrup, which passes through, according to the theory, only so quickly that the bees can continually keep the wick from dripping. The wick would require to be carefully fitted. I am now feeding through the chaff box by a plan which will in due time be exhibited. By no means give foundation, yet shave the capping from one of your overfilled outside combs and place this in the centre of the brood nest if you feel sure the bees are able to bear it. Depend upon it the race will be to those who "make haste slowly." Flour cake is most serviceable, but if you use it and use it you should be sure to expose water in some convenient vessel amongst your hives, and never by any means allow this vessel to be dry. You may if you please feed syrup at the same time that you give flour cake, but syrup feeding in your case seems unnecessary.

#### COVENT GARDEN MARKET.—MARCH 23.

OUR market continues low, both supply and demand being inactive, and the condition of business remains practically the same as last week.

#### POULTRY AND PIGEON CHRONICLE.

##### THE UTILISATION OF WASTE LAND.

WASTE land, as it is termed, is land of an uncultivated and more or less barren surface, and we propose to state certain modes and means by which such land, now comparatively worthless, may be turned to better account. In doing this we shall have not only to consider its present condition, but also its capabilities through the nature of the soil, the climate, and situation. That there are in the kingdom enormous tracts of waste land is admitted by all; and the most difficult point is, not how to improve it, but to make it pay for improvement as an investment or farming transaction. Under the head of utilisation we ought as much as possible to look at the matter as not only a mere change of surface, such as from grass to arable land, or *vice versa*, but also as to its being made profitable on purely commercial principles. It is true that immense tracts of barren and waste land have been reclaimed and made available in various ways, especially for corn produce and provision for stock, and also large portions laid into grass of different degrees of fertility and value.

The home farmer must remember that in undertaking the reclamation of wild, mountainous, and barren soils, although they may vary in the value, several points ought to be considered in reclaiming waste and Heath lands, as well as land long since cultivated, but that from untoward circumstances may have become waste and worthless. 1st, The present value of the land to the owner or occupier; 2nd, The probable cost of reclaiming it; and 3rd, Whether after it is reclaimed the improved value may reasonably be expected to be remunerative. These should be carefully weighed by the home farmer. In taking a review of waste lands converted into tillage or pasture we can find but little encouragement in what has been done, agriculturally speaking, during the past thirty or forty years, simply because the value of agricultural produce, as far as corn is concerned at any rate, has been much reduced. The future prospect, in view of foreign competition, also does not give us much confidence; for although we must admit the great and increasing value of labour-saving machinery, yet the value of manual labour is not only more costly than at any former period, but also less efficient. We must therefore at present set aside any plan of reclaiming land upon previous systems, unless they can be shown to have a reference to special production of particular crops, yielding much larger returns than ordinary agricultural produce in cereals. We thus very much narrow our position, when it is understood we have now only to expect a return for investment in order to obtain specialities in produce, such as market garden produce, woodlands, or useful pastures. The only exception to these to be considered is additions to certain lands, thus improving them, and also beautifying portions of certain estates.

The course pursued in utilising much of the Chat Moss district, through which the Manchester and Liverpool railway was made to pass many years ago, is an illustration of the value which peat bogs may be made to yield. Large tracts were there turned to account by drainage, claying, marling, and liming, the land being utilised as market gardens. In other parts the peat was sold at the rate of £30 or £40 per acre, and the land after being thus cleared of the superfluous bog earth realised by sale a similar price for agricultural purposes. There are plenty of cases where waste

land has been pared and burned on the surface, although previously covered with Heath and Gorse, cultivated for a few years under improved modes of manuring and cropping, and eventually laid into grass. In those cases where the soil and climate were found suitable land was converted into pasture of sufficient letting value to amply provide interest for outlay. This is one of the means open to us at the present time, for in many cases we have heathlands adjoining parkland or other good pasture where it would pay for reclamation in an exceptional way, or for certain objects, not always being easily estimated by money. We cannot here dwell upon this subject to describe practically the work necessary to produce a useful pasture from waste land, because we have done so previously under the heading of "Laying Down Land to Permanent Pasture" in this Journal. Although we have just stated that our past experience of the value of reclaimed land cannot safely guide us in the future as regards the growth of corn, yet we still hold the opinion that turf land is likely to hold its own in value for the purpose of grazing sheep and cattle, more especially upon pastures of moderate value for dairy purposes. To enable us, however, to reap the full advantage of reclaiming land for any purpose we must always reckon upon steam power as our best ally in reducing the land into a state fit either for cultivation or preparation for permanent pasture.

We must now refer to specialities in produce, if we may be allowed to thus designate market garden produce, in either fruit or vegetables, the growth of Hops, &c., as in most cases where the land and climate are suitable very large returns are frequently realised. We will refer to Strawberries as a striking illustration of what may be done upon land hitherto considered comparatively worthless. To show that our own observations are not confined to a particular district we will refer to the cultivation of Strawberries grown for the London and other markets in Kent, Surrey, and Hertfordshire, and their contiguity to the metropolis is of the utmost importance, owing to the perishable nature of this fruit. When in good condition this fruit has a ready sale in the London market; for although it is often glutted with Strawberries from France at the commencement of the season, they, however, generally arrive in bad condition, and are sold chiefly by costers. It is quite common for growers in some of the above-named districts to have 30, 40, or 50 acres under Strawberries, and some of the largest holders of land have as many as 100 acres, and the quantities sent to market every morning is enormous; it is, in fact, on record that one grower alone sends 70 tons of this fruit to market in the course of the season. Good samples, if carefully picked and packed in boxes each containing about four dozen punnets (containing 1 lb. each), will realise from 1s. to 2s. per pound according to the supply; but for fruit of the second size and quality much lower prices have to be taken. The produce is sometimes sold to middlemen, who pick and take the fruit away, running all risks. The price paid is about £20 per acre. Other growers supply the jam makers at the prices of from £20 to £30 per ton; these are of the poorest quality, and are sent to the manufacturers in casks to contain from 70 lbs. to 1 cwt. each. We have evidence that other counties and districts grow Strawberries extensively; the county of Somerset is one instance. Then we have an illustration how far north they can be grown in the fact of waste lands being appropriated for their growth at the foot of the Grampian Hills in Scotland. The latter district supplies the Edinburgh and Glasgow markets to some extent.

Hampshire has within the past seven or eight years become one of the most important Strawberry-growing counties, especially as regards the quality of early fruit. Having during last autumn visited one of the principal Strawberry-growing districts, we were very much interested in seeing a district in South Hants, which we recollect formerly was common or waste land, supporting only a few poor cows and small forest ponies, and being covered in

many parts with Heather, Ling, and Gorse, and the manorial rights of sporting partly exercised over it. Fifty years ago, when we first knew this land, it was not considered worth cultivation, being in most instances a poor clay and gravel, in some cases mixed, any soil which had ever been upon it having for generations been pared off and carried away for fuel by the cottagers. This waste land, consisting of about 1200 acres, was enclosed in the year 1862 and allotted by the Enclosure Commissioners to upwards of two hundred different persons having common rights. One owner lets land to twenty-one cultivators who grow Strawberries almost entirely, and in conversation with some of the growers we were informed that the produce had varied in value from £80 to £100 per acre, the latter sum being made by some of the best cultivators in the best seasons, last year especially having been one of great produce and of fine quality of fruit. From this district some of the finest fruit produced in the kingdom is obtained, and grown upon land never believed to be worth cultivation, and much of it is now comparatively worthless for any other produce, although during the height of the season 25 tons are delivered at a local railway station daily, much of it going to London, Manchester, and towns in the locality, like Southampton and Portsmouth.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—At the beginning of the month this work was greatly in arrears, but lately the weather has proved very favourable for the seed time and the preparation of the land for the root crops. The seeding of Barley although not very early has been suitable, the land being neither too wet nor too dry since the middle of the month. The home farmer will not only require all the animal power of the farm, but the assistance of steam power also; and in order to bring up arrears of field work it is desirable not to trust too much to the weather in our fickle climate. The only way in which we can make sure of a good season for the preparation of the land for Lent corn, and also for the Mangolds and Potatoes, is to take advantage of fine weather, and make use of sufficient cultivating power to bring the land into good tilth at the earliest date. The greatest mistake made in adjusting the working power is to argue that in case the weather should be fine the horses alone will do the needful work all in good time. We, however, ask the home farmer not to expect that the weather will continue uninterruptedly fine, and arrange the working power accordingly. We have often known a fine seed time during March, but in April the rains have frequently prevented labour of consequence being done during the greater portion of the month. When such is the case nothing can compensate for the loss of labour during April, therefore these matters should be anticipated and provided for. This is now the best time for drilling the Mangold seed, and we recommend the stretches to be made about 2 feet apart, the dung being buried in the stretch, so that the land may be horse-hoed at the earliest period, and before those crops cultivated on the flat will bear the horse hoe. The home farmer must remember the best and sometimes the only way to destroy weeds is in their infancy, for in adverse weather if not destroyed whilst in the first leaves they are sure to grow again and cause extra expense. There are soils, however, such as sharp gravel which are best cultivated on the flat, the dung being ploughed under early, and then drill the seed at 2 feet intervals with artificial manures, as full crops cannot be grown without heavy dressings of manure. Besides, if we apply more manure than the Mangold crop requires the land is in a better state for a successional crop, and ready for seeding immediately the roots are cleared off. We seldom obtained a full crop of Wheat after the Mangolds, but have succeeded well with Barley when the Mangold leaves had been ploughed under, and Barley drilled without spring ploughing; in this way the best Barley may be grown. We do not advise the sowing of Carrots until the first or second week in May, but the seed may be prepared; our plan is to rub the burr or husk off with the harvest gloves by hand, the seed will then drill as freely as Mangold or Swede seed. We disapprove altogether the practice of mixing the Carrot seed with ashes or manure, by drilling the seed and manure together at the same time. We have always found the most regular plant can be obtained only by drilling the seed alone after being properly prepared.

*Hand Labour.*—Men are now employed in connection with the seed time. After the seeding of Beans and Peas there will be water-furrowing to be done, because upon many soils where Beans and Peas are usually cultivated the land is frequently flat and retentive of water. The women can be employed in Potato-cutting in readiness for planting; they will then be required in planting, for they can do quite as much as men at such light work, for it only requires activity. Guano and artificial manures as well as ashes should be prepared for use both for application to Potatoes as well as to Mangolds at seed time.

*The Live Stock.*—Damp close weather, which was for a long time unfavourable, has been lately followed by pleasant weather, and the stock of all kinds have improved in consequence where plenty of food has been provided for them. We at present know of cases where little or no food the produce of the farm is remaining, owing

to the damage by severe weather to the roots, and it will certainly cost as much or nearly so as the sheep will be worth to purchase all their food. To sell the sheep would prove nearly as bad, for where stock are forced on the market through a short provision of food in the country prices are sure to find a low level. A portion of the early lambing horned ewes, in consequence of their lambs having been sold, only require a few weeks to feed them into good mutton, and to do this bean meal mixed with cut Mangold will complete the fattening of these ewes better than any other kind of trough food at this time of year. The Dorset Downs and early Wiltshire and Hampshire Down ewes and their lambs must now be fed at great expense to get their lambs fat for the London Easter market, after which the ewes may have Mangold and meal until the grass in the water meadows and Rye on the arable land are fit for feeding. The Swedish Turnips in most instances where not pitted during the frost have but little feeding value where not actually decayed, and in fattening flocks it will require a large outlay to meet the deficiency of the root crops. In the case of breeding flocks, even where only kept in store condition, a more than usually liberal expenditure in purchased food will be necessary, especially on those farms without irrigated meadows. Italian Rye grass is, however, a capital and almost the only substitute which can be relied on for early green food in the absence of water meadows. The fattening bullocks in their boxes will require also in many cases to be put on shorter allowance of root food. This, however, may teach the home farmer a lesson, for but few know how to dispense with large quantities of roots in fattening bullocks with Mangolds and meal cut and mixed; 40 lbs. per day is quite enough to fatten the animal quickly if 2 lbs. of bean meal is added with good sweet oat straw *ad libitum*. The young cattle and dairy cows will still be in the yards and feeding on Carrots, except upon farms where there are water meadows available. With regard to young heifers intended for the dairy in the future, these may be kept in pairs in divided pens with so much space under cover, and so much outside; and when kept in winter and summer until they bring their first calf, they grow up into notice as fine dairy cows, and much larger than those which run the pastures and have to rough it during the winter months. When kept in entirely the manure accumulates under them on the principle of box-feeding, and they return valuable manure for the food consumed.

#### ITALIAN CHEESE.

M. CHARLES PAVIA has published a pamphlet on Italian dairy produce, in which a full description is given of the curious modes of manufacture of Parmesan and Gorgonzola cheeses, a brief notice of which may interest our readers.

M. Pavia speaks of Parmesan as the king of cheeses, "as it contains more flavour and aroma," but we find from the description that it is really a skim-milk cheese, which does not arrive at perfection until it has been kept at least three years. Parmesan cheese is made entirely from cow's milk, and the bulk of it is made from April to October, whilst the cows are fed on green forage. It is stated that the daily production of northern and central Italy weighs about 15 tons, about one-fourth of which is exported. The milk is skimmed once or twice after it has stood from six to twelve hours, the cream being made into butter. The skimmed milk is then placed in a cylindrical boiler and heated by wood fires or by steam to 95° or 100°; a curdling liquid is then introduced, but there does not seem to be any regularity in the system or its results. After stirring or breaking, heat is again slowly applied up to 150° Fahr., colouring being also added. The cheese is then considered completely cooked. The curd is taken out, enveloped in linen, and put in a vat, being turned over once a day, but without any pressure, the surface being salted repeatedly for six weeks. The salt is then scraped off the rind and fine linseed oil applied, which gives the black swarthy coat peculiar to Parmesan cheese. The cheese is then stored in cool dry warehouses, being kept for years, any which show a tendency to decay being quickly got rid of. M. Pavia protests against the cheese-borers being used in testing this cheese, as a "cheese bored may be considered as spoiled." The crust is, at any rate, so hard as to turn the edge and spoil an ordinary cheese borer. This cheese has, no doubt, its admirers in this country amongst those who prefer something out of the common line, but we do not think a cheese so deficient in richness will ever take with the general public. Gorgonzola is of much richer character, being made of unskimmed milk and not cooked. The best of it is always made in the autumn. The fresh milk being coagulated at a moderate temperature, the curd is gently stirred and placed to drain, or hung up in pieces of linen. The curd from the evening's milk is added whilst still warm to that put in the vat in the morning. At the joining of the two lots of curd a green or blue mould is formed, much esteemed by some, and which adds greatly to its value. The cheese is turned when it gets dry enough, but never subjected to any pressure, a little salt being rubbed on the coat of the cheese. It is kept at a low temperature through the winter, and ripens in the warm weather of the following summer.

It is mentioned as a peculiarity of the manufacture of all Italian cheeses that they drain and become dry without any of the pressure which is considered necessary in the making of all other foreign cheeses, and which it is suggested may be a matter of "pure prejudice on the part of other nations." We lately heard a friend express the antipathy he felt to the use of macaroni, due to a sight of its manufacture in the filthy surroundings of the towns of Southern Italy; and though we think the natives of the district in the north, where dairy produce is made, compare favourably in the matter of cleanliness with their southern brethren, we much doubt if a personal inspection of the making of butter and cheese in Italy would increase the favour in which they are held. —(*Journal of Applied Science*.)

#### VARIETIES.

AGRICULTURAL PROSPECTS.—An entire week of exceptionally fine weather has proved of inestimable benefit to agriculture, and the greatest possible progress has been made with spring sowings on the lighter soils. The young Wheats, though backward for the season of the year, begin to assume a decidedly healthy appearance, and are creeping along the ground in a manner which is always considered to be indicative of a good start in the life of the Wheat plant. On light lands sowing is now in full swing, but the clays turn up cold, although dry on the surface. The Wheats, in the great majority of instances, have the appearance of being likely to pull through; nitrate of soda is not very dear this season, and its judicious use later on would probably turn out a profitable speculation. If this weather would but last throughout the month agricultural prospects would be considerably brightened thereby. Foot-and-mouth disease is declining, but liver-rot is working sad havoc amongst flocks in the Midland and West Midland districts. In Cheshire it is very prevalent amongst young cattle, and the dread of it nearly everywhere will be likely to lessen the demand for stores very considerably. —(*Mark Lane Express*.)

— LITTER FOR RABBITS.—A "RABBIT-KEEPER" writes:—"I shall feel obliged if some of your readers will kindly inform me the best kind of litter to use for Rabbits. Hitherto I have used common hay, but my stock is now exhausted, and I find best hay rather too expensive. The next most convenient thing for me to obtain is barley straw, but some of my friends tell me it tends to produce vermin on the Rabbits. I shall be glad to know if this is so, or whether I may use it with safety."

— COUNTY ARMAGH BEE-KEEPERS' ASSOCIATION.—A correspondent informs us that the British Bee-keepers' Association has exerted great interest in bee-keeping in Ireland, and that the first meeting of the above Association was held on the 11th inst. under encouraging patronage. Mr. George Greer moved that an Association be formed, to be called the County Armagh Bee-keepers' Association, for the purpose of encouraging the intelligent, humane, and proper keeping of bees. Some years ago an Association was formed in England, called the British Bee-keepers' Association. There were only eight members at first, and now it numbered several hundreds. This Association worked by means of local organisations throughout the country, and the central Association was the means of collecting knowledge from other countries, such as Italy, Switzerland, and France, and also aided by giving money prizes and keeping up a "bee tent." This year an Irish Bee-keepers' Association had been formed, and there was no reason why it should not work as well in Ireland as in England. There was a very large profit to be made by honey, as a large sum of money went out of the country for honey and wax; and, again, the bees were not destroyed. The Association would show the members how to make up the honey in an attractive and saleable form, and would also try to get a market for the honey produced. An ordinary labouring man, who did his day's work, could easily find time to look after ten hives. Rev. Mr. Lett seconded the motion, which was passed unanimously. The following were appointed office-bearers:—Patroness—the Baroness Von Steiglitz. President—Sir Wm. Verner, Bart. Vice-Presidents—Mr. M. C. Close, M.P.; Mr. J. N. Richardson, M.P.; Major Stewart Blacker, and Mr. John Hancock. Committee—Dr. Lynn, Messrs. Wm. Allen, James Ussher, Thomas Best, and George Hazlett. Treasurer—Mr. T. G. Peel. Secretaries—Mr. G. Greer and Rev. H. W. Lett.

## POULTRY AND PIGEONS

### LA FLÈCHE.

At the recent Paris Exhibition we were much struck with the size and quality of the specimens of the La Flèche breed exhibited in the dead poultry classes. Our appreciation of their merits was not diminished by subsequently partaking of one of Madame Aillerot's prize birds at an English table. This bird had been killed over three weeks when we tasted it, and it was one of the finest fowls under the carving knife we have ever seen. The white meat was abundant and delicious, while the legs were fully equal in quality to those of a Turkey. We are aware that most attempts which have hitherto been made to rear these birds in any large quantity in this country have not been very successful. The Houdan and the Crève have established themselves firmly on our soil, and have become acclimatised, while the third leading French breed still has but a precarious footing here. We think that if its merits as a table fowl were more generally known a more persistent attempt would be made to overcome the first difficulties of importing it to a fresh home. It is true we have the Dorking as our champion table variety, but we are bound to confess that we have never seen any Dorking dressed for table which could compare with the best specimens of La Flèche at Paris.

We cull the following information as to the table qualities of the La Flèche and the mode of fattening it from the pages of *Le Poulailier*. When fully grown the cocks weigh from  $7\frac{1}{2}$  lbs. to 9 lbs., the hens from  $6\frac{1}{2}$  lbs. to  $7\frac{1}{2}$  lbs. These weights are those of the fowls of full age as they run in the yard. M. Letrône, to whom M. Jacque confesses his indebtedness for much of his information about the breed, considers that its origin is unknown. Its celebrity may, however, according to old historians, be dated from the fifteenth century. M. Letrône considers that it had a more ancient origin. These choice table fowls were originally produced at Mans, later at Mézeray, and finally at La Flèche. The industry has long since been abandoned at the first-named place, it is declining at the second, and it is only at La Flèche and the neighbouring municipalities that it is still fully maintained. The La Flèche fowl, so well adapted for fattening, are also, says M. Letrône, very robust and but rarely sick. They readily become acclimatised in any country to which they may be transported, and their good qualities are easily preserved, providing that in-breeding to excess be avoided. They can habituate themselves to any food when they have attained a certain age, but they should at first be supplied with food which is at least similar to that which they are accustomed to in their own country. When allowed their liberty they do not ramble much, provided that they are supplied with green food. The fineness, the delicacy, and the exceptional flavour of their flesh are easily perceivable even when they have not been crammed; but these qualities are brought out in perfection by the fattening process, to which both the pullets and cockerels are submitted at the age of seven or eight months. The cockerels are left at liberty as long as is thought necessary, but they are kept apart from the pullets. If this be attended to they are much better disposed to fatten, and the necessity for caponising them is avoided. The pullets are submitted to the fattening process before they have laid. These birds do not come to maturity until they are nine or ten months old, but from this seeming disadvantage arises the advantage that they continue to grow through the winter, and make grand specimens in the spring time, when good fowls are very scarce. The usual poultry food in the La Flèche district is whole white wheat, which is given three times a day. This food is used because the birds are very voracious, and have at certain periods a tendency to run to fat.

The chickens are after the first few days fed upon a paste composed of bran and meal. This is continued for six months with this variation—that as the birds grow the quantity of bran used is increased and the quantity of meal diminished. Green food is always supplied in abundance. The process of fattening adopted is by no means a secret in the localities where the business is carried on. Malicorne, Arthézé, Courcelles, and Vilaines hold the first rank for fine products and the number of persons engaged in the industry. It is to the district of La Flèche that these and other towns which are engaged in the trade belong, and it is to the town of La Flèche that all the feeders bring their fat birds on market days; it is there that they may be seen for sale by hundreds at a time.

The special work of fattening appertains chiefly to the farmers

and certain small husbandmen whom they call poultry-keepers (*poulaillers*). Both these purchase in the markets or from their neighbours those pullets (which they call *gelines*) which appear most suitable for fattening. To produce those fine specimens not less esteemed than the pullets which are called *coqs vierges*, young cockerels of the year are submitted to the same process of fattening as the pullets, with this difference—that they take longer to fatten.

The finest pullets attain the weight of nearly 9 lbs.; the finest cockerels about 13 lbs., and they have been known to surpass these weights.

The poultry-keeper fattens at the same time from fifty to one hundred birds. The season generally commences in October, and lasts about five months. All round the sides and on the floor of a room or other place suitable for the purpose small coops are made. These are constructed of cheap rough wooden laths, and cost no more than the time it takes to make them. The height of the coops should be from 20 to 24 inches, the length in proportion to the number of birds the coop is to contain. Six birds are as many as should be put in one coop, and there should be just space enough for them to lie down without being able to move about. All direct light is shut out, and the chinks of the doors and windows are carefully stopped, so that the fresh air is almost excluded. To accustom the birds to the system of feeding and the forced seclusion to which they are about to be submitted, they are placed for the first eight days in a rather dark place, and are fed upon a paste composed of the same meal with which they are subsequently crammed, mixed, however, with a half or a third the quantity of bran. During this period they are given water to drink, and allowed to eat as much as they please.

The meal of which the cramming balls is made is ordinarily thus composed; one-half buckwheat, one-third barley, and one-sixth oats. The coarse bran is separated from the meal. Every day enough of this meal is mixed with sweet or sour milk to feed the birds that night and the next morning. Some add to the mixture a little hog's lard, especially towards the end of the fattening period. This paste, which should neither be too hard nor too soft, is rolled into pellets (*pâtons*) of the form of an olive, about  $2\frac{1}{2}$  inches in length, and rather over half an inch in diameter. The crammer at the feeding times, which ought to be regularly observed, takes three birds at once, ties them together by the legs, and places them on his knees, then by the light of a lamp he commences by giving them each a spoonful of water or skim milk. Some, however, do not give the birds this drink. He next puts a pellet into the mouth of each bird in succession, and to facilitate the swallowing process he gently presses his finger and thumb along the neck of the bird down to its crop. The advantages of taking three birds at once are, that it gives time to each to swallow the food, and that the filling of the bird's crop is more gradual. During the first days of the cramming process the crops of the birds are only moderately filled, but the number of pellets given is gradually increased; in this manner the number of pellets given at each meal ultimately reaches from twelve to fifteen. It is essential that the pellets should each be dipped in water before being given, as this makes them more easy to swallow.

The time necessary for fattening varies. Some fowls take but six weeks, others two months. Sometimes, if the bird is well disposed to take his food, he is fattened for as long a time as possible, and it is thus that phenomenal weights are attained.

Some birds cannot be completely fattened, and the poultry-keeper must exercise his discretion as to these, and kill them at their best. Losses cannot be avoided, and these sometimes take place in spite of every care and attention.

No straw or other bed is given for the birds to lie upon, and their coops are not cleaned out during the entire period of fattening. M. Letrône very justly remarks, that if the exhalations arising from this neglect of cleanliness are necessary to aid the fattening process they cannot but be injurious to the poultry-keeper who has to spend much of his time in the noxious atmosphere. We do not doubt that many of the losses which are said to arise owe their origin to this neglect of cleanliness, and we should strongly urge any of our readers who may feel inclined to give the La Flèche mode of fattening a trial to omit that item in the programme.

### THE MODERN DORKING.

It is a long time since I read anything in your poultry columns more interesting than Mr. Cresswell's remarks at page 224. Most of us amateurs are more ready to accept the above gentleman's dictum on Dorkings than any other authority, as it is well known he is thoroughly practical, and as a rule follows a middle course, which is very agreeable. I have lately come into possession of

some Dark Dorkings from one of the oldest breeders of them. They are the real original Dorking, and have the points so accurately delineated by Mr. Cresswell. They are really splendid fowls, and it would indeed be a pity were another form substituted. What I want to suggest is this, Let all interested in Dorkings read carefully Mr. Cresswell's remarks, adopt his opinions as a standard to breed to, and there will not be the slightest danger of the Dorking losing its best qualities.—J. MUIR, *Margam*.

#### CROSS-BRED POULTRY.

It has often seemed to us a pity that some of the many poultry fanciers who wish to make their yards useful as well as ornamental do not take a little more trouble in trying the results of various first crosses of pure breeds. We should indeed be the last to depreciate really pure-bred poultry; the particular requirements of each breeder can be satisfied by them, and their special excellencies are known beforehand; the advantages to be derived from keeping them distinct are manifold, and we have often dilated upon them. There are, however, cases in which first crosses are advisable. We say first, for beyond these the special benefits derived from a cross generally seem lost. Cross-bred birds are proverbially hardy, and can be reared in adverse circumstances. The subject of this article has been suggested to us by the frequent appearance in show schedules of classes with liberal prizes for cross-bred fowls, which one would expect to find well filled with useful plump-looking birds. Such is not, however, the case; indeed we hardly remember having seen a class with more than one or two pens really adapted to the table. The best class of the kind we ever saw was two years ago at Scarborough; but even then great size, such as it is well known that the Brahma-Dorking cross produces, seemed to have been more thought of than the production of small-boned plump fowls. At Guildford, one of the centres of the poultry-breeding districts of Surrey, liberal prizes were offered by a gentleman for cross-bred fowls, but the winners of them had the appearance of being picked up from a miscellaneous lot. Now the schedule of the Birmingham Dairy Show is before us. In it are classes with four prizes in each both for trios of cross-bred fowls of 1880 and 1881, open to general competition; there are also similar prizes confined to Warwickshire tenant farmers and cottagers. The season is almost too far advanced for the offer of these prizes to stimulate breeding this year, but we hope that it may do so against the dairy show of another year. The Brahma-Dorking cross is often quoted as the best; birds, however, produced by it must be eaten early or they become coarse; they are generally too large in bone. Houdans or Crèves crossed with Brahmas produce very hardy and useful fowls, the hens generally wonderful layers. Dorking and Game has always been a favourite cross with us; we suspect, however, that Polish and Dorking would produce a most useful fowl and excellent for the table. We have of late quite disproved in practice the theory that Polish are delicate fowls; Dorkings, too, in fairly favourable circumstances are as robust as most breeds. We are much inclined to think that the union of the two would be a great success; at any rate this and many other crosses are quite worth while trying, and we shall be glad to know the results of any experiments. Of course there are in all such experiments two distinct objects which may be aimed at—firstly, the production of a good table fowl, and secondly of a race of good layers. For the former the most hardy, healthy, and shapely specimens should be selected; for the second it is also of great advantage that hens known individually as the best and earliest layers should be chosen. We are persuaded that in this respect pullets as a rule follow their mothers, and that consequently much might be done by careful selection. Year after year in our own yards the same hens lay first, and often birds of three or four years old quite anticipate all the pullets. Such are very valuable, and might be made the beginning of improved strains.—C.

#### POULTRY NOTES.

It is instructive to observe the effect which different seasons have upon the health of poultry. A good indication of it is the proportion of eggs, and still more the proportion of fertile eggs we get. We have always observed that in winters and springs when there are many alternations of frost and thaw there are few fertile eggs. This winter, in spite of the intense frost, in which our birds suffered terribly from frost-bitten combs, we have had a very large proportion of fertile eggs, indeed we have hardly had a clear one. We attribute it to the fact that the spells of weather have been longer and less variable than usual at this time of year,

and that almost ever since the frost the ground has been moist, and so given plenty of insect food.

We hear of some good hatches in incubators; doubtless the absence of drying winds has favoured artificial hatching.

We observe in the schedule of the Birmingham Summer Poultry Show that the rules of the Poultry Club are in a general way adopted, among them "Any exhibitor who has been disqualified for fraudulent practices is ineligible to compete at this Show;" also, "No person is allowed to exhibit borrowed birds." The general adoption of such regulations will check much cheating. We suppose that the schedule in question has been drawn up with the object of encouraging the breeds of poultry suitable to farms. If so we regret that some of the sorts remarkable as layers, such as Minorcas and Leghorns, have no classes. We believe that there is in England quite as wide a field open for the producers of eggs on a large scale as for the breeds of poultry.—C.

#### OUR LETTER BOX.

**Materials for Eggshells (W., Essex).**—The best supply for laying hens is a heap of bricklayers' limy rubbish. Oyster-shells burned in the fire until they can be easily pounded are also efficient in supplying calcareous matter for the formation of the eggshells.

**Field Culture of Potatoes (N. E.).**—In reply to your questions we must first take into consideration your statement that you have grown Potatoes with advantage in different fields for your own use, but not for sale; also, that your arable land is a strong loam fairly drained, and that you have a good supply of farmyard manure. All these points are favourable, and induce us to think that the growth of Potatoes for sale would answer a good purpose, especially as your land is within two and a half miles of a railway station. We should think that with ordinary care and cultivation you may calculate upon about 8 tons per acre as an average crop in your loam. You do not, however, say whether your land is undulating or lies flat; this is very important in determining to some extent the distance of planting between the lines. In planting such sorts of Potatoes as Magnum Bonum and Champion we think that if the land is undulating they may be set at the distance of 30 inches between the lines and 15 inches in the rows, and that having been liberally dressed either with yard dung or guano, and horse and hand-hoed, and earthed up in the usual way, the crop may probably escape the disease in a great measure even in a wet season. If, however, the land lies flat with a strong subsoil the Potatoes should be set at 36 inches apart between the lines, and 15 inches in the rows. When they are set at this width the cultivation may be different, and done by the one-horse plough entirely instead of using the scarifier; and as soon as the Potatoes are up so as to plainly see the lines, the plough should be used between them, turning away two furrows, one on either side of the lines—that is, four small furrows, leaving only about 15 inches unmovd where the Potatoes are growing; this space only will require hand-hoeing as soon as the plants will bear it. Then as soon as the weeds are dead turn two furrows up to the plants on either side; this will destroy all the weeds and leave the land in a loose and healthy state for the Potatoes to root in. But as soon as the runners begin to extend, instead of earthing or hilling the plants in the usual way with a single furrow on each side, let two furrows be again turned towards the plants. After this is done carefully there will be a deep furrow between the hills of Potatoes, and it should be deep enough to break up some soil below where the plough has previously worked, then complete the work by the use of the double mould board plough in the furrow. This will give a free run for any excess of rainfall, and the broken subsoil will readily absorb a large quantity of water, leaving the hills high and dry, which is the best safeguard against the disease. We have, moreover, in this plan a space between the hills wide enough to admit the sun and air so essential to healthy vegetation, and by the plan we have stated nearly all the tubers will be of a marketable size in consequence of the space the roots have to feed in. We reckon 5 cwt. of Peruvian guano per acre to be equal to 15 tons of the best yard or town dung.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

13th.—Fine but overcast; sunshine only for short time at noon; lunar halo.  
14th.—Fine, with bright sunshine.  
15th.—Very fine bright day.  
16th.—Fine, with some haze; fog in town.  
17th.—Fog in early morning; very fine spring-like day.  
18th.—Fine bright hot sun; high wind, and much dust blowing.  
19th.—Very fine, bright, and clear.

Temperature still above the average, but the nights colder than in the previous week; grass frost on three mornings; no rain, and much dust.—G. J. SYMONS.

### THE HYACINTH.

ITS PROPAGATION AND CULTURE IN HOLLAND.

**A**MONGST the numerous spring-flowering bulbs there is none that equals the Hyacinth in graceful appearance, brilliant colouring, and delicious fragrance. It is of the easiest culture, and so accommodating that it readily adapts itself to a great variety of conditions, for the bulbs may be successfully grown in water, damp moss, sand, cocoa-nut fibre refuse, soil, or almost any other moisture-retaining medium.

There are several species of Hyacinths, but the subject of my remarks is the Oriental Hyacinth (*Hyacinthus orientalis*), which belongs to the natural order Liliaceæ, and was introduced into this country from the Levant in the latter part of the sixteenth century, and is a native of Asia Minor, Syria, and Persia. It was not, however, until the beginning of the eighteenth century that it attained a foremost place as a florists' flower. An idea of the position it obtained when it came to the front may be realised when I state that a sum equal to £200 has been obtained for a single bulb; now very fair bulbs of good sorts can be purchased for 6d. each. During the time of Queen Elizabeth starch was obtained from the bulbs to stiffen the large ruffs which the nobles and Court beauties of that period employed. The Hyacinth presents us with the very rare phenomenon of a black flower; and it is worthy of remark that the principal colours, if we omit white, are the three primary ones—viz., red, blue, and yellow, embracing every shade of light and dark in these colours. It would therefore lead us to suppose, arguing from this fact, that if the laws of fertilisation were properly understood, that by artificial crossing we ought to be able to produce them of every shade of colour. Such experiments must, however, be left with the Dutch cultivators, the process of raising new sorts being very tedious and the climate and soil of England unsuitable for such experiments. The perfumes of the Hyacinth are almost as varied as the colours, some being particularly delicate and delicious, whilst others are coarser, but all are pleasant and refreshing when diffused in the atmosphere. I heard it said of an enthusiastic cultivator, that he could tell the names of his collection by smelling the flowers. Whether this is possible or not I am not prepared to say, but the perfume varies so much that I believe it would not be difficult to distinguish many of them by that means.

The Dutch growers who supply the English market produce an enormous number each year, of which some idea may be gathered from the fact, that according to a survey made some years ago about six hundred acres (five hundred acres being near Haarlem), were then devoted to the rearing of Hyacinths,

Tulips, and similar bulbs, affording constant employment for a large staff of experts. The cultivation is an important addition to the income of Holland. The official returns for the exports in one year alone (1876) state the value of such exports to be equal to nearly £140,000; at the present time the income is doubtless much greater, as it has been increasing annually. The Dutch cultivators employ various methods of increasing their stocks and obtaining a supply for the different markets. Some scoop out the apex of the bulbs, others cut through the base crosswise with a sharp knife, the operation in each case being performed a short time before planting the bulbs, the object being to cause them to produce offsets.

It may be interesting to recount the method employed by a celebrated firm on their extensive grounds near Haarlem, as it was recently fully explained to me by a friend from Holland, who has been conversant with the process for many years. Previous to planting the bulbs they cut through one or two of the outward layers in a longitudinal direction, and when completed the sections represent the quarters of an Orange when the peel is removed: they are then ready for planting. The ground is prepared some time previously by being liberally supplied with a top-dressing of well-decayed manure composed of about two parts of cow and one part of horse manure, which is laid upon the surface of the soil several inches thick, and afterwards well forked into the ground to the depth of 8 or 10 inches, in which the bulbs are planted about 2 inches deep. The planting is commenced in January, and when finished the Hyacinths require little further care until the growth appears above ground in March or the beginning of April, when the trouble of the cultivator begins in consequence of the frosts that frequently occur at that period. At this time it is not uncommon to see large tracts of ground covered with mats to protect the young growths from injury. When the season arrives for gathering in the crop the bulbs are carefully lifted, cleansed, and packed away until the time for planting arrives.

The young bulbs are planted from year to year until they become sufficiently matured for blooming, which if properly managed generally takes about five years, although it frequently happens that more time is occupied in growing them to this state, and occasionally it is accomplished in a less time. The bulbs are then ready for testing, and are again planted in the same manner and permitted to grow until the flower-spike has advanced and is about to show its colour, when very great care and attention is given to each batch of bulbs in order to ascertain that all are true to name and colour. As soon as the blooms open sufficiently to permit this they are carefully cut off to allow the whole strength of the plant to be economised in perfecting the bulb. The beds are laid out in long narrow lines. In each bed or number of beds are kept separate kinds, which are constantly watched, and if one plant appears of a different colour or variety it is marked so that it may be properly classified. Every bed is carefully checked by the above method. All this care and attention is absolutely necessary in order to keep the varieties quite distinct, otherwise we should never be able to depend upon any kind we purchase being true to name. The cases when we obtain a wrongly named bulb being so very rare, is a proof of the care exercised by the cultivators in this respect.

By the month of June the bulbs are ready for gathering, when they are carefully taken up, cleaned, and laid out upon

racks and turned several times daily until they are dry, when they are packed in paper or Buckwheat chaff, and are ready for repacking for export to England and other countries to which they are annually consigned. A few words may be said upon the districts in Holland most suitable for producing fine bulbs. I am informed that the best bulbs are only grown in the neighbourhood of Haarlem, say of a few miles around that centre, which may, therefore, be said to be the chief grounds in the district. The soil at this part is very deep and sandy, and admirably adapted for producing fine Hyacinths and other bulbs. Other parts of Holland have been tried at different times, but only with indifferent success. This fact may be interesting to those who, like myself, had previously imagined that in almost all parts of Holland the Hyacinth could be grown to perfection, and be valuable in guiding those who may be interested in obtaining the best bulbs only, particularly when required for exhibition.

I will now give a few hints upon the choice and purchase of the bulbs, which generally arrive in this country and are ready for sale in September. The characteristics of a good bulb are solidity, soundness, and symmetry, showing that it has been previously grown with care and well ripened. A smooth and neat appearance and large size are no indications of its value. Some are both large and smooth, whilst others are very rough and small in comparison, and both may be equally good. Those that are heavy in proportion to their size and do not yield to a slight pressure are the most reliable, and seldom fail to produce good spikes. If a bulb is light and feels soft or spongy when slightly pressed with the fingers, it should be discarded, as it cannot be depended upon. The best time to purchase them is as soon as they arrive; you have then a better chance of obtaining good bulbs than by waiting until a number of selections have been made. They will keep if placed singly in any cool dry place where they can receive plenty of air until such times as you wish to start them. I would advise everyone to take notice of the bulbs before planting them, which will soon enable them to form a tolerably correct estimate of the bloom they will produce.—JOHN HAIGH.—(*Read at a Meeting of the Sheffield Horticultural Society.*)

#### GLASS STRUCTURES FOR AMATEURS—VINES.

(Continued from page 186.)

*Border.*—Where the natural soil is not of an unsuitable nature for the growth of Vines there is no need for excavating and forming an artificial border. A loamy rather light soil will only require thoroughly draining with 3-inch drain tiles, at a depth of not less than 3 feet nor more than 4 feet. Soils that overlies gravel may not require draining, but the efficient drainage of the soil is absolutely essential to success. If the soil be shallow over the gravel it must be deepened by the addition of fresh compost, so as to make it 30 inches deep. The whole of the border should be trenched to a depth of 2 feet 6 inches, presuming there is that depth of good soil; if less make it of the required depth by raising it with the fresh material. In trenching a sprinkling of half-inch bones may be placed between the layers, and if the soil is not of a calcareous nature a tenth of old mortar rubbish may be added between the layers, and mixed by pointing each layer over with a fork before placing on another layer of soil. Avoid manure unless the soil be very sandy, when it and turfy loam of rather stiff texture may be added to the extent of one-sixth each. Many soils are so favourable for Vine culture that great expense is often incurred in forming borders by no means so good as the soil excavated. Indeed there are very few soils in which Vines may not be grown with a satisfactory result; what is needed is a free open soil and thorough drainage. In wet low-lying sites, instead of excavating and forming a pit (it may be in clay), the border should be kept at least one-half above the surrounding level, going no deeper than to secure a solid base for the walls and bottom of the border. Nine inches or a foot depth of rubble should be placed at the bottom for drainage after the drains have been properly laid, the drainage being secured by a layer of turves grass side downwards. The top 3 or 4 inches of a pasture where the soil is medium-textured loam, light rather than heavy, is the best staple possible. This should be chopped up roughly, adding a tenth part of old mortar rubbish, and about one part in twenty-five or thirty of crushed bones; those thoroughly incorporated form an excellent border. If the loam be close-textured an addition may be made of charcoal in a similar proportion to

the bones. Those near towns may obtain oyster shells, and these calcined are a capital addition to Vine borders. The material should be mixed and made up with the border in dry weather, and be one-third higher than the intended level to allow for settling. Only a part of the border need be made in the first instance, a width of 6 feet being sufficient to serve the Vines for two seasons; and in the case of the half-span and span-roof house the Vines should be confined to the inside border for two or three seasons, to secure the thorough establishment of the roots there before admitting them to the outside, which should not be made until required.

*Vines.*—All the structures illustrated in the last volume were to accommodate six Vines 4 feet distance apart, commencing 2 feet from the ends. With but one house the ambition is to obtain a supply of ripe Grapes over as long a period as possible. My selection shall be one Mill Hill Hamburg, which is often confounded with Black Champion, the latter having oval berries, the former round and sometimes oblate, and hammered. It is freer and earlier than Black Hamburg, and, as stated in the "Fruit Manual," is "a noble Grape of first-rate quality, having the appearance of the Dutch Hamburg with the quality of the Black Hamburg." It is a Vine that tells more than any other the falsity of judging by appearances, its foliage being pale green and sickly-looking, yet its constitution is good; it bears abundantly, and the Grapes invariably finish well. A fitting companion for that is White Frontignan, which is sure to find favour with the home consumer for its excellent, abundant, and certain bearing, and very rich juicy crackling flesh, with fine Muscat flavour. Black Hamburg is indispensable and needs no eulogy, being the most deservedly popular of Grapes. A fitting companion for it is Foster's White Seedling, which is a showy Grape of first-rate quality, and will hang some time in good condition, as will also Black Hamburg. Lady Downe's is a valuable kind and an abundant bearer. Its companion white may be found in Muscat of Alexandria, the most delicious of Grapes; and though requiring more heat than the others, it ripens fairly well in the same house with the preceding, but like the Hamburg does not hang well over Christmas; consequently if late keeping is a consideration I would advise Alnwick Seedling, which though new is of proved excellence, or those that look upon new things with disfavour may have two instead of one Lady Downe's. Grapes will then be ensured from July to May.

With a view to a maximum of produce Vines may be planted inside the house on the opposite side to where the permanent Vines are shown in the span-roofed house (page 462, last volume), allowing them to fruit heavily for the first two or three years and then cut them out; but unless the owner has resolution they had better be omitted, for planting two where there is only room for one is the sure way of courting failure.—G. ABBEY.

#### STANDARD ROSES.

It seems rather my fate to be on the unpopular side. I stand up almost single-handed for Hybrid Teas, and now the current seems setting almost equally against standard Roses, in which I believe far more fervently. The Briar standard is the English stock. It is found in all our hedges, and if only properly selected and properly cared for flourishes in all our gardens, most especially in strong soil, where it does far better than the Manetti; also I maintain, other things being equal, a good standard cut-back yields finer blooms. It stands to reason that a larger body of sap will flow up a stem so much larger in diameter; while, again, it is far easier to bud than the dwarf Manetti or seedling Briar stocks. How charmingly Shakespeare describes that process—

"You see, sweet maid, we marry  
A gentler scion to the wildest stock,  
And make conceive a bark of baser kind  
By bud of nobler race."—(*Winter's Tale*, iv., 3.)

When budded, if care is taken to wax over the Briar top, there is no reason, with a good stock, that it should not flourish for years, always excepting a winter like the present. But there are exceptions to all rules, and even this seems to be ending in a survival of the fittest. We are getting a good idea of the hardiest Roses. There are Briars and Briars no doubt, and some smooth-wood sorts are never likely to live long or to stand much hard weather; but give me good strong soil and plenty of room, and I should distinctly prefer a bed of standards to any other. I venture to think they are by no means exploded, and very little likely to go out of culture altogether. There are many places they occupy where Roses on the Manetti or on their own roots would be entirely out of place, and utterly unable to produce the effect required. At the same time I quite sympathise with Mr. Thomson's melancholy

feeling in looking at the bed of four hundred standards. If I might offer a suggestion it would be not to root them all up, as the Briar is probably alive half way down, and likely to throw out very strong side shoots for budding.

To turn to another point. All readers of the Rose Journal must have rejoiced to find "WYLD SAVAGE" again discussing about his particular pets—Tea Roses. I do not despair of even seeing him return still more fully to his old love and again exhibit,

"On revient toujours  
À ses premiers amours."

Or in more homely English—

"Old porridge is sooner heated than new-made."

One other point I have to remark on, and that is what has been written respecting Maréchal Niel on its own roots. Abundant proof has been given that it may be as glorious in this way under glass as any other, and the descriptions have been enough to make us all long to order for it a palace of crystal. As far, however, as my own experience goes I have found that, though it strikes readily enough, the plants on own roots are always feeble. Possibly, if one could wait long enough (like the man who bought a raven, to see if the bird really did live a hundred years), it might give satisfaction; but budding on the Banksia or seedling Briar gives far more rapid growth. The late Mr. Webb of Calcot near Reading grew it to a large extent from cuttings as well as otherwise, but then there are some soils which will do almost anything. I find on a light hungry soil that there is hardly a Tea Rose of any kind on its own roots which will supply me with an exhibition bloom.—A. C.

#### TOMATO CULTURE UNDER GLASS.

As the demand for fresh Tomatoes now extends over the greater part of the year, the cultivation has necessarily undergone a great change. To grow Tomatoes to the best advantage a house specially adapted for them is required, and in these dull times a new house cannot always be erected; but in gardens where the cultivation of the Pine Apple has nearly ceased to be one of the main features of the establishment, one of the Pine-growing structures might advantageously be converted into a Tomato house, as there is at disposal a good command of bottom heat, and a broad bed the length of the house.

Sow the seeds in a rich soil in pans or pots, and plunge them in gentle bottom heat from January 1st to the end of April, according to the time the plants may be required. Prick out the young plants in small pots, and when these are filled with roots shift the plants into 5-inch pots. The soil should be rich. Perhaps some persons fail in growing Tomatoes because they employ too poor soil. In preparing a bed employ rich loam, well-decomposed cow manure, leaf soil, and a little sand, and place out the plants directly they are large enough. Plants raised from cuttings inserted in September or October are very suitable for early planting. They should be from 6 to 7 feet apart, with a stake to each. Maintain a steady night temperature of 55° to 60°, rising to 70° or 75° by day when the sun shines brightly, affording them also a little bottom heat and a moderate degree of moisture in the atmosphere, and as the days lengthen increase the temperature. The utmost care should be taken in training and tying. Let the main stem extend to the top of the house before stopping it, and pinch the side shoots the first joint from the flower. The growth which ultimately comes from that should be permitted to extend until flowers appear; then stop it again, continuing the process until the house is filled with growths. Do not allow the foliage to become too crowded, and attend to watering, especially during dry weather, weak liquid manure being beneficial when the plants are heavily cropped with fruit. Supplies of fruit will thus be obtained until November.

To have Tomatoes all the year round pot culture must be resorted to, plants being raised from cuttings taken in July and grown on with careful attention. Their final shift should be into 10-inch pots in a rich soil, and fruit them in a house where the temperature is between 60° and 70°. In November do not cut down the plants that have been bearing all summer; on the contrary, lower the temperature of the house and diminish the supply of water, this being the period of rest. Clean the house thoroughly, washing all the glass and woodwork, and limewash the walls. The plants during summer have a tendency to become crowded; therefore cut out all superfluous wood in winter, leaving enough for another season. A good top-dressing of rich loam and well-decomposed cow manure should be given to the bed to invigorate the plants. Assuming all this has been carried out by the middle of December, the plants should be started the second week in January with a night temperature of from 55° to 60°, rising to 70° or 75° on bright days with a little bottom heat and a

moderate degree of moisture, increasing all as the season advances. If the crop was large last season assuredly it will be better this, the plants bearing abundantly with a decided superiority in quality of fruit. This mode of Tomato culture is not generally practised; it is nevertheless good, hence this record of it in the Journal.—WM. MUIR.

#### CHIONODOXA LUCILIAE.

ONE of the most beautiful hardy spring-flowering plants is that represented in the accompanying engraving; and though it has only been in cultivation during the past two or three years it has already attracted much attention, and is likely to become very popular, rivalling the Scillas in its lovely blue flowers. A recommendation of inestimable value is its extreme hardiness, which has been well proved during the past severe winter in several gardens, but particularly in Mr. Ware's Hale Farm nurseries, Tottenham, where clumps of plants are in excellent health and

Fig. 57.—Chionodoxa Luciliae.

flowering most profusely. From a single plant selected from one of these clumps the engraving has been prepared, and well represents the general character of the plant both in habit and the form of the flowers. In colour the latter are light blue, nearly white in the centre, the blue tint becoming darker towards the points of the petals, thus imparting a very delicate and distinct appearance to the flower. A rich soil and well-drained border are needed to grow it to the best advantage, similar soil being also required when the plant is grown in a pot, for which it is very well suited.

It is a native of Asia Minor, and was first found by Boissier on the Western Tmolus in 1842, about 1000 feet above sea level; but the honour of introducing it to cultivation is due to Mr. G. Maw of Benthall Grange, who thus describes the locality where it was found:—"The specimens were obtained the first week in May, 1877, in ascending the Nymph Dagh, east of Smyrna, at elevations of from 3000 to 4300 feet. At the lower level it was

out of flower, but near the summit of the mountain a great mass of it was met with in full splendour, forming one of the most sumptuous displays of floral beauty I ever beheld; a mass of blue and white resembling *Nemophila insignis* in colour, but more intense and brilliant. Close at hand were Tulips of several species, yellow *Fritillarias*, *Galanthus Elwesii*, yellow *Gageas* of several species, *Crocus*, *Colchicum bulbocodioides*, *Scillas*, &c.—a perfect paradise for the bulb-collector and the botanist."

Since then the plant has been several times exhibited at the meetings of the Royal Horticultural Society by the introducer and others, and is now becoming well known, but is rather scarce at present.—L. C.

#### MORE ABOUT FOOD AND VEGETABLES.

POPULAR prejudice is at present almost an insuperable barrier to progress in practical acquaintance with the properties of food and the mode of preparing it for use. Whether or not in ten years' time the children now under instruction in Board and Government schools will be sent out wiser and better economists than their parents remains to be proved. I have doubts. Things are too easily found. All the materials for the system of education must be supplied. Little account is taken of waste or carelessness. It might astonish many a poor student of former days who, by much self-denial and long waiting, came by the coveted books that brought him knowledge and led him perhaps afterwards to fame, could he see the recklessness with which books are treated now, and the little care that is taken to make children responsible for the care of materials they handle.

Hitherto the parents of boys and girls entering their first service almost invariably impress upon their children advice they are sure implicitly to follow—viz., to eat as much animal food as they can. Soups and vegetables are often rejected in favour of a more ample supply of meat—meat, we may observe, more gross and indigestible in proportion as artificial feeding has been resorted to to bring the animal to an earlier maturity and a marketable value.

Cheap sugar may be a boon; but here again prejudice fails to understand that adults often vitiate the value of the nourishment of a whole meal by an undue use of sugar, which in excess creates fermentation, does not agree with many persons, and often aggravates rheumatism and other kindred affections of the blood. Bread is frequently indiscreetly given; sweet and delicious crusts thrown aside the sooner to reach the crumb; mastication is too much dispensed with; and the new and soft pulp, too easily bolted, opens up the avenues to indigestion, languor, and other ailments.

Lectures on cookery appear as yet to have made little perceptible impression, not to say alteration, in our national habits. Cabbages are still boiled with the bacon, parting with all their saline properties in as little water as possible; Potatoes generally getting too much, though steaming is becoming more usual than it was. A lady friend of mine, asked what she thought could be done to improve the condition of girls and instruct them better, replied that she thought we were as far from success as ever, instancing the case of an intelligent girl who had been seven years in her service preferring to cook mutton chops by putting them on a cold dripping tin in the oven to doing them as she had been taught to do. Another lady mentioned that in her household she found increasing difficulty in persuading girls to enter the kitchen as scullery or kitchen maids, where, though generally the hours of labour are shorter and the pay greater than in other departments of domestic service, more care and more patience are necessary to satisfactory results.

But these remarks are already too long and much remains to be said. Let me conclude, in compliance with a suggestion from "WILTSHIRE RECTOR," by a receipt for a simple pudding where there has been a full meal of meat and when vegetables are scarce.—A. M. B.

*Lemon Water Sago Pudding.*— $1\frac{1}{2}$  pint of cold water, the very thin rind of half a large Lemon or one small one, the juice of one large Lemon or two small ones, 2 ozs. loaf sugar, one small teacupful of pearl sago. Bake very gently in a slow oven for two hours. Cold in summer it forms a refreshing jelly, and can be turned out like a mould.—A. M. B.

EXTENSIVE CUCUMBER PLANTING.—Many of your readers here were much interested in the account of Mr. James Whittaker's new Cucumber house (page 178). But why does Mr. Whittaker prefer it in one length to several shorter and more easily managed houses? and is it a span or lean-to? We have several Cucumber houses around here, but notably those of Mr. Wm. Thomas, who has six houses, each being 100 feet long, and all in a square block as it were; this I should imagine is a much better plan. Perhaps

Mr. Whittaker has reasons for building the house in one length, if so possibly he will inform us what the advantage is.—W. ROBERTS.

#### ROSES IN POTS AT SOUTH KENSINGTON.

AMONGST the many objects of interest at the Exhibition held in the conservatory on the 22nd inst. there were few that attracted more attention than the charming group of Roses in pots exhibited by Messrs. Paul & Son of Cheshunt. The plants in themselves were perfect, of the size that most amateurs can appreciate, and certainly exceeded in beauty those huge giants which the same firm is in the habit of exhibiting later on; while the opportunity that it gave of seeing some of the newer varieties, and seeing what their merits are in pots, confirmed in most respects the judgment already formed of them. Duke of Teck has established itself, not only as being one of the best exhibition scarlet-coloured Roses that we have, but also the very best of that colour for pot cultivation. Another seedling from Cheshunt was also exhibited, which, if it stand the test, is to bear the name of one of our most successful rosarians. It is a Duchesse de Caylus style of flower, but with the vigour of constitution and habit which that very beautiful variety lacks, and on account of which it is so seldom found on the exhibition table; should it not belie its promise it will be a valuable flower. Madame Alphonse Lavallée is a very beautiful Rose, and when I say it bears a very suspicious likeness to Marie Baumann that point will be readily conceded, but I fear it is too much like it to be considered distinct. It has the same weak footstalk and the same foliage; in fact it seemed as like Marie Baumann as Marguerite Brassac is to Charles Lefebvre. William Warden, a sport from Madame Clemence Joigneaux, originated by Messrs. Mitchell & Son of Piltown, and which I have more than once noticed in the Journal, was charming in the freshness of its pink flowers; and if it retain its character, which most of the sports of Madame C. Joigneaux do not, it will be a Rose much looked after. Another fine Rose was Egeria, raised by Mons. George Schwartz, but sent out by Mr. Henry Bennett. It is an improved Princess Mary of Cambridge, and is beautiful both in colour and form. Near it was a plant with only one bloom on it of my old friend Margottin's Gloire de Bourg la Reine, a brilliant scarlet flower with most intense deep centre, giving it a most attractive appearance. It was not very full as shown, but it is sure to meet with favour for the brilliancy of its colour. These were the most noticeable of the new flowers; and amongst the older varieties were, as has been already noticed, some beautifully flowered and well-grown plants. Altogether the exhibit was a cheering one—a herald, too, of good things to come.—D. Deal.

P.S.—I would take this opportunity of thanking several kind correspondents, some known and others unknown, for expressions of sympathy and offers of help in the present condition of my once flourishing collection of Auriculas. I must, however, as I have said, wait patiently and see before I venture any further whether the experiment I am about to try will be successful.

#### COTTAGE GARDENING.

HAPPY is the cottager who was able to dig or trench his garden as soon as the crops were cleared from it in autumn, for now he has the soil sweetened and softened by the severe frosts of the past winter ready to his hand for cropping, and he is able to take advantage of the first fine weather of spring to plant his early Peas, Beans, and Potatoes. William Russell, to whom I let a cottage with a sadly neglected garden last autumn, is evidently aware of this, for he has contrived to trench quite half of it during winter, and when I went past the other day cropping had been commenced, and the trenched soil was evidently quite ready for it.

Potatoes are the most important vegetable in a cottage garden, and the best varieties are Myatt's Ashleaf, Early Rose, and Magnum Bonum—all sure and abundant croppers. As the early Potatoes are taken up fork up the soil lightly, and sow Early Snowball Turnip row by row at once without waiting till all the Potatoes are lifted, and thus secure a useful second crop. Of Peas the first should be Ringleader, and the later sowings G. F. Wilson or Champion of England. Do not sow two rows of Peas side by side, but have them 12 or 20 feet apart, with lower-growing vegetables between. Try also to have Scarlet Runner Beans in single rows, as by so doing the crop is much heavier than if one row is crowded by another. Grow Student Parsnip, James's Intermediate Carrot, White Spanish Onion, Cole's White or Red Celery, Wheeler's Imperial Cabbage; and for winter Drumhead Savoy and Cottagers' Kale, Leamington Broccoli, and Veitch's Autumn Giant Cauliflower, Giant White Cos and All-

the-Year-Round Cabbage Lettuce. These are all really good vegetables, equally good for table or prizewinning.

By all means sow seeds early, but do not do so till the soil is quite ready. It is far better to wait a week or two for this than to risk the losses which so often occur where seed is sown in soil that is cold and wet. Pig dung and wood ashes are the cottagers' manure, and he can want no better if he has enough of them. House slops, especially soapsuds, are good for all growing crops; none should be wasted, but all should be poured in a covered tub and thence applied regularly, especially to Celery, Cabbages, Lettuce, Onions, and Peas and Beans. Strawberries, Raspberries, Currant and Gooseberry bushes, are all wonderfully improved by it. When applied in hot weather it is well to stir the soil first with a hoe and to scatter a little litter over the surface afterwards, or much of the goodness of the sewage is lost. Frequent stirring of the surface is always good for the crops, keeping down weeds and opening the soil to the sweetening influence of the air. In applying sewage or water do not pour it upon the crown of the plants, but close alongside them. Lettuce and Celery are both liable to have decayed centres if watered carelessly. Take care to water thoroughly; an abundant watering twice or three times a week is far better than a mere wetting of the surface daily.

All cottagers should keep bees, and I would again point out the importance of having plenty of sweet-scented flowers for them. What can be more beautiful than bowers and arches of Honeysuckle? The first sowing of Sweet Peas should be ready for the sticks now; more should be sown, and a regular succession of them and Mignonette kept up till as late as possible in autumn.—EDWARD LUCKHURST.

#### MR. DAY'S ORCHIDS.

TO-DAY (Thursday), the sale of the noted collection of Orchids at High Cross, Tottenham, commences at Stevens's rooms, and will be continued at intervals until one of the finest collections in the kingdom has been distributed. It is a matter for general regret among orchidists that the numerous rarities and handsome specimens which have taken so many years to bring together should be again widely dispersed; but there is the redeeming point, that many who have long envied Mr. Day the possession of some rare species will now have an opportunity of obtaining them. Therefore a few notes upon this fine collection of Orchids may be of interest to some readers who have not had the privilege of visiting it.

About ten houses, chiefly span-roofed structures, and from 30 to 60 feet or more in length, were on my visit exclusively occupied with Orchids, all the chief genera being represented by large numbers of plants. Cattleyas and Lælias are particularly fine, such well-known forms as Cattleya Trianae, C. purpurata, Lælia elegans, and L. crispa being represented by very handsome specimens. The pretty little Lælia cinnabarina was flowering, its small orange-coloured blooms being suggestive of its ally L. harpophylla. Vandas and Aerides are similarly abundant and vigorous, among the former being some fine examples of V. tricolor, including the beautiful Dalkeith variety, the rare V. Parishii, V. Lowii, and V. gigantea, the latter bearing several of its large yellow flowers. Phalaenopsids, too, constitute a great feature, and have this year been uncommonly fine; even now there is a handsome display of P. amabilis, P. Schilleriana, and P. grandiflora. Of the latter there are some extremely beautiful varieties, one bearing about a dozen flowers, each over 5 inches in diameter, and with fine petals 2 inches broad. One form of P. amabilis, too, is especially noticeable for the deep tint of red in the lip. The rare P. Mannii (see page 257) is also flowering freely. In the same house Angraecums are doing remarkably well, A. sesquipedale and A. citratum being especially noteworthy. One specimen of the latter had a spike about 1½ foot long, and bearing forty flowers—the finest example I have seen of this beautiful Orchid. All the principal Cypripediums are grown, some of the plants being very large. One now in flower, named C. barbatum grandiflorum nanum, is remarkable both for the great size of the flowers and the dwarf habit of the plant, to which characters it owes its name. Dendrobiums, Epidendrums, Oncidiums, Saccolabiums, and numerous genera are similarly largely represented, and to indicate the species grown would fill a volume. Among the cool house Orchids Odontoglossums are grandly represented, many hundreds of plants being grown. O. crispum, O. gloriosum, O. vexillarium, O. cirrhosum, O. odoratum, O. Halli, O. Pescatorei, O. triumphans, with many others, some well known and some extremely rare, entirely fill a large house, while Masdevallias are almost as numerous. Of the latter the rare M. trochilus was recently in flower,

and the true M. Chimæra, both more singular than beautiful, but highly interesting to botanists. It is almost needless to say that Mr. Gedney, the gardener, had all the plants in excellent condition, and no doubt some high prices will be realised for them. These necessarily brief notes scarcely do justice to this grand collection, but it will enable some idea to be formed of its extent.—L.

#### DESTROYING THE AURICULA APHIS.

IN reference to an article on Auriculas and woolly aphids by "D., Deal" (page 209), I may state that we were quite free from that pest until April, 1878, at which time we had some new varieties, which were placed in a frame with our stock. I did not discover the insect until the following August, when the plants were repotted, and I then found the new plants badly infested on the roots and the collar, and it had spread to a great extent over the whole stock. I dissolved 4 ozs. of soft soap in a gallon of water, and added a quart of strong tobacco water; I then had the plants shaken out, and dipped the roots and collar up to the foliage in the mixture. I placed them on the potting bench for a quarter of an hour, and then washed the roots in clear water and repotted the plants. The old soil was burnt, and the pots were placed into a large tub of water containing soft soap. I have never found any trace of woolly aphids on the plants since. We have had three different batches of new Auriculas, all of which have been accompanied by the same pest, which has been destroyed in the same way, with the exception of two plants, one of which was watered with paraffin and one with Fir tree oil, half a pint of oil to 2 gallons of water. I forget to what extent the paraffin was diluted, but the roots and the aphides were killed in each case although the plants lived. If "D., Deal," could be induced to try the former experiment I think he might still linger on as an Auricula grower.—J. L.

#### FANCY PANSIES.—No. 3.

(Continued from page 497, last vol.)

AFTER the terrible weather we have experienced of late it is somewhat difficult to fix the mind or memory upon a subject associated with warmth and brightness; but the advancing season and the hope it engenders act as a stimulus to the effort. Where a family is as numerous as Fancy Pansies, and where there are so many resembling each other, a selection becomes no easy task, especially as there has been no attempt made to divide them into classes as in the case of Show varieties. Under these circumstances I submit the following list of forty varieties with every deference, knowing that what may suit my taste will be rejected by others equally able to judge that important qualification harmony of colour. Smoothness, form, size, and dissimilarity have been considered, and many old favourites have been mercilessly rejected because of some imperfection. The varieties named, I may say, have been selected from upwards of five hundred that have passed through my hands, and they are the kinds from which I should elect to choose a box of twenty-four or thirty-six for a strong competition. The list, it should be remembered, includes the best of the new varieties sent out last year.

*Agnes M. Scott.*—Dark violet purple blotches; upper petals shaded lilac, edged all round with straw colour. *Attraction.*—Very dark blotches shaded with rich crimson, edged all round with yellow. *Cabul.*—Dark crimson self; good eye, large blotches. *Capt. Tomlin.*—Violet blotches, shaded pink and edged white; upper petals deep lilac edged white. *Champion.*—Pure white self; large solid dark velvety blotches. *Countess of Strathmore.*—Clear white self, with large solid blue blotches. *Duchess of Edinburgh.*—Primrose self; large dark blotches. Smooth and of good form. *Effie Walsh.*—Large violet purple blotches on all the petals, with a well-defined white margin round each petal. Very smooth and constant. *Frederick Gifford.*—Maroon blotches; very neat eye; upper petals and margin of blotch rich earmine, with a narrow wire edge of yellow round all the petals. *Fred Perkins.*—Creamy violet; rich velvety black blotches, surrounded by rosy crimson. *F. W. Leland.*—Upper petals violet veined with crimson; under petals large, dense violet blotches margined with pale lemon. *George Rodgers.*—Dark velvet purple self, with soft blotches and good eye, with a very narrow white edge round the under petals. Smooth and of good substance. *George Wood.*—Very rich light crimson, with dark blotches on side and under petals. *Gladiator.*—Very large dark blotches edged and veined with crimson and yellow; upper petals heavily margined with crimson. *Grand Monarch.*—Very dark crimson shaded with maroon; large solid purple blotches. *J. H. Borrowman.*—Dark brown self, with dense mulberry blotch; neat eye. *J. T. D. Llewellyn.*—Reddish mulberry shaded with magenta; solid dark blotches, neat eye,

white brow. Smooth, of good substance and constant. *John Currie*.—Rich bronzy crimson edged with light yellow; dark purple blotch; back petals veined with purple and white. *John Young*. Fiery maroon blotches, edged with carmine and yellow. *Jubilee*. Bright golden yellow self; fine eye, large solid black blotch. *Marquis of Bute*.—Cream self, very large blue blotches. *Major Molesworth*.—Rich amaranth self, with solid violet purple blotches; fine eye, white brow. *Miss Horn*.—Large dark blotches, edged pure white; upper petals white and lilac. *Mrs. Crawley*.—Dark rosy purple, with a clear margin of pure white. *Miss Darling*.—Solid maroon blotches; neat eye; upper petals and margin of under petals yellow, with puce margin round upper petals. *Mrs. Hubbard*.—Violet purple blotches shaded with deep rosy lilac, edged all round with pure white. *Mrs. Longfield*.—Yellow and crimson, edged with white. *Mrs. Scott Plummer*.—Bronze and yellow; large crimson maroon blotches. *Mrs. Jamison*.—Deep golden yellow self; solid blotch. *Mrs. E. H. Wood*.—A beautiful deep orange, edged with rosy purple. *Miss M. Methven*.—Rosy crimson; light purplish blotch, edged with pure white. *Pollie*.—Solid dark blotches; violet purple margin, edged round the petals with white. *Robert Conan*.—Exceedingly large brown blotches, edged with bright yellow. *Rev. Archie Bell*.—Very dark blotches edged with cream; upper petals veined with bright purple and cream. *Thomas Grainger*.—Very rich crimson, with black blotches on the side and under petals. *The Bride*.—Pure white self; large dark velvety blotches. *W. H. O'Shankey*.—Dark blotch; reddish crimson margin. Smooth and of good substance. *W. M. Welsh*.—Maroon blotch; upper petals shaded with crimson lake. *Wm. Melville*.—Back petals rosy purple; fine dark blotch edged with yellow. *Waverley*.—Rich bright crimson self; large dark blotches; solid eye.

Of the above the best twelve for exhibition purposes, having regard to evenness of size and dissimilarity, are Attraction, Capt. Tomlin, Duchess of Edinburgh, F. W. Leland, George Rodgers, J. T. D. Llewelyn, Miss Minnie Methven, Major Molesworth, Mrs. Crawley, Mrs. Jamison, Mrs. E. H. Wood, and Wm. Melville. These are all good growers, and may be depended upon for bloom from May until the end of September.

Before concluding I should like to express the hope that before long an attempt may be made to bring Fancy Pansies into classes. The high position they have so rapidly attained, not only as exhibition flowers but as bedders—(for I know of no prettier sight than a bed of Fancies where their beautiful and varied colours are grouped for effect)—claims for them this attention, and the rapid improvement of certain types will in a short time render the task less difficult than it appears at first sight. We have now a charming variety of selfs, broad and narrow, white, crimson, and yellow-edged, and Picotee-edged, and it appears necessary that certain well-defined rules should be laid down or the family will run wild beyond redemption. Unless something be done the question will soon prominently arise as to what is a Fancy and what is not. I have already seen in different catalogues the same flower classed as a Show and as a Fancy. This has arisen solely because there is no authoritative decision as to the size of the blotch, and until this is arrived at there will be confusion. A large bold blotch is essential in a Fancy, and no limit can be placed upon its size; but in a Show there must be a limit, or the flower loses its distinctiveness.—M. H. MILLER, *Leek*.

### MULCHING FRUIT TREES.

GARDENERS and fruit-tree growers generally are well aware of the advantage of mulching the ground over fruit-tree roots, but the time of doing it is not so well settled; consequently some mulch early in spring, others at midsummer, and many not until the fruit is gaining size and maturing in autumn. In my opinion the matter is of too much importance to be carried out in this indefinite manner, and it would be well if we could all agree as to the best time to mulch and act accordingly. Giving my experience and opinion towards this, I may say that all our principal fruit trees, especially those against walls, are always mulched before the buds begin swelling in spring, and of all the times I have seen tried that appears to be the best. The trees have the full benefit of the nourishment from the manure throughout the whole season of their growth, and they need this as much when the fruit is forming and the young growths starting as they do in autumn. In fact, inducing any tree to start freely into growth in spring is of more advantage in autumn than any little extra attention just at that time. Light straw manure is of no use for mulching, as it neither keeps the soil moist in dry weather nor affords nourishment. For mulching I prefer good cow dung before it is much decayed, and always employ it in this state. The manure need not usually be spread more than 4 feet from the

stem of the tree, and in some instances less than this will do. When applied in spring to last all summer it should not be less than 4 inches thick, and it is a good plan to previously break up the surface of the soil over the roots with a fork.—M.

### THE TULIP.

HAVING read with great interest your report of Mr. Shirley Hibberd's lecture on the Tulip in last week's *Journal of Horticulture*, I send you the following passages from the "Life and Letters of Ogier Ghiselin de Busbecq," just published by Kegan, Paul, & Co. De Busbecq started for Constantinople Nov. 3rd, 1554. At the beginning of the "Life," vol. i., page 69, the author says: "A tradition still lingers at Bousbecque of the beautiful garden which he formed, and the Lilacs, Tulips, and other new plants with which he filled it;" and in vol. i., on page 62, the author says, speaking of Vienna in 1572-3: "Here he received parcels of Tulip bulbs and other rare plants from Constantinople;" and on page 107 of vol. i. of the "Letters" De Busbecq says: "After stopping one day at Adrianople we set out to finish the last stage of our journey to Constantinople, which is not far distant. As we passed through these districts we were presented with large nosegays of flowers, the Nareissus, the Hyacinth, and the Tulipan (as the Turks call this last). We were very much surprised to see them blooming in midwinter, a season which does not suit flowers at all. There is a great abundance of the Narcissus and Hyacinth in Greece. Their fragrance is perfectly wonderful; so much so, that when in great profusion they affect the heads of those who are unaccustomed to the scent. The Tulip has little or no smell; its recommendation is the variety and beauty of the colouring." See also in the "Life" vol. i., page 3: "We cannot turn to our gardens without seeing the flowers of Busbecq around us; the Lilac, the Tulip, the Syringa. So much was the first of these associated with the man who first introduced it to the West, that Bernadin de St. Pierre proposed to change its name from Lilac to Busbequia."—SAN JUAN.

### STRAWBERRY FARMING.

(Continued from page 152.)

*Marketing*.—Until within the last few years the great bulk of the Strawberry crop found its way in a fresh state to the dessert table, and the demand, though steady, was limited and subject to much fluctuation. At the commencement and close of the season prices ruled high, but during the height of the gathering the markets were frequently glutted, and prices consequently fell to a low figure. The rapid growth of the trade in preserved fruits has now, however, opened an outlet for almost any quantity of Strawberries. Although the price of Strawberry jam is considerably higher than that of most other small fruits, it is so much esteemed that stocks of it in makers' hands are generally first exhausted. The probability is that for years to come the demand for this fruit will be practically unlimited. Fortunately for growers there is small chance of foreign competition doing much harm, as the fruit is too perishable to be imported from any great distance in a fresh state, and the quality of foreign-made preserves is not likely to take the taste of the British public.

Large growers ought to provide the means of taking advantage of either the home or foreign market as prices may tempt. Growers in this quarter were for several years entirely at the mercy of a few leading local confectioners, who made the prices to suit themselves, and frequently by refusing fruit in the very height of the season created such a panic that prices suddenly fell 50 per cent., and then they bought all they could get. Latterly, however, the district has been visited by buyers from Dublin, Liverpool, &c., and, under the influence of this competition, and the opening of markets for fresh fruit, prices have risen to a steady figure of £28 to £32 per ton.

There is considerable advantage in having at least part of the crop purchased by a confectioner. The cost of picking is considerably less than when gathering for table use, no selecting being necessary; and as the fruit may be taken before quite ripe, twice a week instead of thrice is often enough to go over the ground. In rainy weather and when the fruit is soiled much would be lost were it not for the confectioner; thus a few shillings less per cwt. may be more than made up by the greater economy in wages and waste. For preserving purposes the fruit is always sent out in small barrels. Empty butter casks are very often used for this purpose after being thoroughly cleaned, re-hooped with iron, and fitted with hinged lid, hasp, and handles. As the railway rate for empties are comparatively trifling these barrels are usually made strong enough to last several seasons. Of course the fruit is first gathered in baskets without the husks, and all soiled fruit

kept by itself. The latter is dipped in a tub of clean water and left to drip for a few minutes before being added to the dry fruit, and the whole should be left in the baskets in a cool place until about to be sent off. If possible the fruit should be despatched the same day it is gathered, as it is very liable to mould in the barrels.

Various systems are employed for sending Strawberries to market in a fresh state. The most usual is probably the punnet or chip basket. The Newcastle market favours 10-lb. trays of wood. Others use hampers with Cabbage or Rhubarb leaves to separate the fruit into quarts or pints. When I began to raise Strawberries I saw that I could not tolerate either system. The punnets being round could not well be packed in square hampers without loss of space. They necessitated some expensive means of preventing them crushing into each other. The 10-lb. trays were too large. Cabbage leaves were not to be thought of. Finally I resolved on having a light box to hold a quart. Fifteen of these form a tier in a light wooden crate holding three tiers of boxes, with a pair of light racks to prevent the upper tiers touching the berries below. These crates of forty-five quarts weigh when sewed up about three-quarters of a hundredweight, and being fitted with iron handles are quite manageable by one man. After three seasons' experience I cannot see that I can improve upon them. They carry the fruit safely hundreds of miles, and they are being generally copied by other growers. They are not at all expensive, each quart box only costing me one halfpenny, and the crates about 2s. each.

The fruit is gathered at once into these boxes, four or six of which fit into a sort of basket on feet carried by each picker; green Strawberry leaves are laid on each box when filled, and the filled boxes are exchanged for empty ones and transferred to the crate. Since I adopted this system I have found that it is very similar to that usually employed in the United States.—WILLIAM RAITT, *Blairgowrie*.

#### TROPÆOLUM MAGNIFICENT.

THIS is a bedding plant of excellent habit, with flowers of great brilliancy and beauty. I question if any other plant so effective and striking has been introduced to the flower garden during the last forty years. For many years I have annually visited the gardens of the Earl of Ellesmere at Worsley Hall, under the able management of Mr. Upjohn. In September, 1879, I noticed several large oblong square beds in front of the Hall densely covered with this Tropæolum, which was then new to me. Mr. Upjohn said he did not know what its name was; he found it at a small place and begged some cuttings. I remember the first appearance of Defiance, Miss Trotter, and Crimson King Verbenas, and the introduction of the brilliant Pelargoniums Glow and Vesuvius, but this Tropæolum for effect eclipses them all. I asked Mr. Upjohn for a few cuttings, which were readily given. He told me it is rather difficult to strike in autumn, and difficult to keep in winter. Some of the cuttings were inserted in a cold frame, and some in a warmer place. Those in the former succeeded best. About twenty weakly plants were wintered here, and in the spring last year about one thousand plants were obtained from them, and sold amongst other bedding plants. Wherever seen they were admired, and they gave great satisfaction to all who tried them. Probably this Tropæolum never had a name, and hence I have called it Tropæolum Magnificent.

It is very dwarf and compact in habit, and answers well for massing, ribbon, and scroll borders in the flower garden. My difficulty last year was to find plants dwarf enough to associate with it in a ribbon border. I planted Lobelia compacta in front of it, and Viola Purity behind it, but they were both much taller. Mr. Upjohn fringes his Tropæolum beds with Cerastium tomentosum or something similarly white and dwarf. The great characteristics of the variety are its productiveness of flowers, which come from every joint, and its persistency in flowering till frost kills it. In the spring under glass it is as easily struck as a Verbena, and therefore can be rapidly multiplied by thousands. Last year I resolved not to trust again to autumn-struck cuttings, and hence I kept some spring-struck plants in pots, which are now yielding cuttings.—A. PETTIGREW, *Salé*.

#### BENTLEY'S SPRAY DISTRIBUTOR.

It is not often we have to record any additions to the garden syringe; but in the ingenious appliance under notice we have somewhat of a novelty, and one that is certainly not without its uses. In addition to forcing out water from the syringe, hose pipe, or other connection to which the contrivance is attached, the operator can at will apply an insecticide to any particular plant to which it is necessary—that is to say, he can first distribute the insecticide

mixed with water, and by the next movement of the piston eject pure water. At the end of the syringe (see fig. 58) is a reservoir which is moveable; when turned one way the insecticide which it contains is ejected, mixed with water in the form of spray, and turned in another direction water alone is discharged. The action of this peculiar arrangement is shown in the annexed section (fig. 59), and described by the inventor, Mr. T. H. Bentley, Scarborough:—"A represents the main channel of the syringe. *c* represents the valve or inlet of the water, which when drawn in by the piston passes direct down the channel B into A; but the water being forced out—i.e., to water the plants, it returns up channel B, where it meets a certain amount of resistance; this causes a portion of the water to

Fig. 53.

Fig. 59.

force its way through the hole leading in to the reservoir of the poison bulb *c*, which forces in its turn the oils to be mixed into chamber *b*, where the insecticide and main stream of water comes into violent contact in its passage towards the spray-producer *r*, and it is at this stage that the mist is produced by the following simple and effective manner. Two holes are drilled through the jet or spray-producer, which holes meet at a certain angle. The two columns of water, meeting as they do by force of pressure from the syringe, strike together with such force as to thoroughly disintegrate each other and convert immediately the columns of water into myriads of atoms which is the mist or spray, and by this process impregnated with sufficient insecticide to cause the destruction of insect pests. Should the plants be healthy and clean and only require watering, then the bulb *c* has merely to be turned round, when a letter *w* is observed on the top of the bulb, denoting pure water only is passing. The bulb is filled with the liquid by the screw *g*. A letter *r* is also stamped on the bulb or screw; this denotes that poison is charged with the water, but by simply turning the screw round so as to

bring it underneath the row of jets the w appears, and the syringe then is to be used as an ordinary one with such a nozzle attached for spray or a more powerful jet as the operator pleases."

Mr. Bentley's circular shows the appliance in various forms and its modes of application; and we have only to add that the syringe we tried worked admirably. The inventor informs us that Messrs. Corry, Soper, Fowler, & Co., are appointed wholesale agents for the trade.

### ROYAL BOTANIC SOCIETY.

MARCH 30TH.

THIS Society's first spring Show of the year was held yesterday in the corridor and conservatory of the gardens at Regent's Park, and proved one of the largest and best that has been held in recent years. Bulbous plants were particularly numerous, and the miscellaneous collections were both abundant and of excellent quality. The weather was fine, but a cold wind prevailed.

**HYACINTHS.**—Two classes were devoted to these, one for amateurs and the other for nurserymen, the collections in each to contain twelve plants, single spikes. Three collections were staged in the amateurs' class; Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, taking the first prize with handsome plants, the spikes and bells very fine. Mr. J. Boulton, gardener to Captain A. L. Patton, Alpha House, Regent's Park, was a close and good second; Mr. H. Eason, gardener to B. Noakes, Esq., North Hill, Highgate, being placed third with rather poor specimens. Four nurserymen's collections were staged, the chief award being secured by Messrs. Osborn & Sons, Fulham, with an even collection of plants with massive spikes. Messrs. H. Williams & Son, Finchley, and Messrs. Cutbush & Son, Highgate, followed with neat specimens.

**TULIPS.**—There were also two classes for Tulips—twelve pots, four kinds, three bulbs in a pot. Three amateurs' collections were staged, Mr. Douglas again first with excellent specimens, followed by the same exhibitors as in the class for Hyacinths. The chief nurserymen's collection was from Messrs. Osborn & Sons, even and good. Messrs. W. Cutbush & Sons, Highgate, and Messrs. W. Wiggins & Son following in the order named. The other classes for bulbs were devoted to Narcissi, Crocus, and Amaryllises, twelve pots each of the two former and six of the latter. Messrs. Osborn and Mr. J. Douglas were the prizetakers for Narcissi, both showing healthy well-flowered examples. An open and an amateurs' class were provided for twelve Cyclamens. In the former Mr. H. B. Smith, Ealing Dean, and Mr. Wiggins, gardener to H. Little, Esq., Uxbridge, were the only exhibitors, securing the first and second prizes for well-flowered plants. In the amateurs' class Mr. Wiggins and Mr. E. Baxter, gardener at White Lodge, East Barnet, took the prizes, the latter exhibitor also being awarded the third prize in the open class. Messrs. Cutbush, Mr. Baxter, and Messrs. W. Wiggins & Son, Tottenham, were awarded the prizes for Lilies of the Valley in the order named.

**AZALEAS.**—Prizes were offered in two classes, amateurs and nurserymen, for six greenhouse Azaleas in 12-inch pots. They were not very well represented. Mr. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham, was first in the amateurs' class with well-flowered specimens; Mr. G. Wheeler, gardener to Lady Louisa Goldsmid, Regent's Park, was second; and Mr. R. Butler, gardener to H. H. Gibbs, Esq., St. Dunstons, Regent's Park, was placed third with rather thin specimens. Messrs. B. Peed & Sons, Norbury Nurseries, Streatham; and Mr. H. James, Castle Nursery, Lower Norwood, were the only exhibitors in the nurserymen's class, staging rather indifferent specimens. In the open class for twelve stove and greenhouse plants Mr. J. Wheeler was first with medium-sized but healthy specimens, the most noticeable being *Hibbertia Reedi* and *Boronia pinnata*. Messrs. B. Peed and Son were second with a neat collection, including a fine variety of *Anthurium Schertzerianum*. Mr. R. Butler was third with moderately good plants.

In the open class for six Amaryllises Mr. Wiggins was awarded the first prize with fair plants, Mr. Baxter being second with specimens bearing smaller flowers but more brightly coloured. Mr. J. Douglas staged the only collection of hardy Primulas, and obtained the first prize for neat specimens, among which plants of *Primula viscosa* were particularly noticeable. He also secured a similar award for six specimens of *Deutzias*. Messrs. Osborn and Sons were awarded the first prize for nine hardy herbaceous plants, and Captain Patton obtained a similar award for twelve pots of Crocuses.

**MISCELLANEOUS EXHIBITS.**—These were very numerous, and constituted a large portion of the display. Messrs. Veitch & Sons exhibited very extensively. One group of about one hundred Roses in pots was very attractive, the plants being in extremely healthy vigorous condition, the blooms fine for the time of year, and the colours rich. About one hundred and forty fine Hyacinths were also staged, some of which were in even better condition than last week—a sufficient indication of their merit. Amaryllises, Coleuses, and other new plants were also shown in large numbers. Silver medals were awarded for the Roses, Hyacinths, and Amaryllises. Mr. B. S. Williams, Upper Holloway, was awarded a large silver medal for a very large and beautiful collection of plants, chiefly comprising Orchids, Amaryllises, and new plants. Many very handsome specimens were shown, particularly *Cypripediums*, and a *Lycaste Skinneri* in a 10-inch pot was shown with thirteen flowers. Among the novel-

ties and varieties those especially noteworthy were *Laelia harpophylla*, with small orange-coloured flowers, narrow self-coloured petals, in the way of *L. cinnabarina*; and *Curcuma zedoaria*, a zingiberaceous plant with a spike of yellow flowers in the axils of reddish or pink bracts. Messrs. Paul & Son, Cheshunt, had a pretty group of small Roses in pots, well grown; among them a plant of a new *Rosa polyantha* named *Anna Maria de Montravel*, with fine clusters of small double white or blush flowers—an attractive variety. A specimen of *Hydrangea japonica* tricolor was also shown with foliage variegated with white and yellow. A bronze medal was awarded for the group, and the first prize for the only collection of six Roses in pots in the nurserymen's class. Messrs. Wm. Cutbush & Son, Highgate, sent large and handsome groups of Tulips, Azaleas, both indica and mollis varieties, and six boxes of Camellia blooms representing some very good varieties. A silver medal was awarded for these groups. Messrs. J. Carter & Co., High Holborn, obtained a large bronze medal for a large group of Hyacinths, *Deutzias*, *Dielytras*, and *Spiræas*, all in good condition. Messrs. Osborn & Sons, Fulham, staged a collection of about two hundred Hyacinths in excellent condition, the majority being considerably better than they were at Kensington last week. A similar collection of Tulips was also shown. A large silver medal was awarded. Silver medals were also awarded to Mr. H. B. Smith, Ealing Dean, for a collection of two hundred remarkably well-flowered Cyclamens, both the white and crimson varieties being excellent; to Messrs. Wm. Paul & Son, Waltham Cross, for a dozen boxes of Camellia blooms, comprising an excellent selection of varieties represented by large and finely-shaped blooms; and to Mr. J. Wiggins for a group of well-grown Cyclamens, Amaryllises, and Cinerarias.

Mr. H. Eason exhibited a collection of unusually fine *Lachenalias*. They were placed thickly in 32 and 24-size pots, some having over twenty very large spikes of flowers. Messrs. Henry Williams & Sons, Fortis Green, Finchley, sent a group of Hyacinths in satisfactory condition. To the former a certificate, and to the latter a bronze medal were awarded.

Captain Patton, Alpha House, Regent's Park, staged a similar group of Hyacinths, Tulips, *Spiræas*, and *Dielytras* to that staged at Kensington, the condition of all the plants being highly satisfactory, some improvement in the two last-named being noticeable. A silver-gilt medal was deservedly awarded for this handsome group.

Botanical certificates were awarded to the following exhibitors for the plants mentioned:—To Messrs. J. Veitch & Sons, for *Anthurium Andreanum*, which has been frequently described; *Gymnogramma schizophylla*, an elegant little Fern from the West Indies, with neat bipinnate fronds, the pinnules linear and bright green. On the plant shown the fronds were 6 to 9 inches in length, but they attain a much greater length than that, are viviparous, and frequently branch towards the base. To Mr. B. S. Williams, for *Laelia harpophylla*, a pretty and rare Orchid, with neat orange-coloured flowers, the petals and sepals narrow, and the lip slightly crisped; *Asplenium Sanderi*, a graceful species suggestive of *A. caudatum*, but with smaller pinnate fronds, the pinnæ being crenated on the upper margin; and *Actinopteris radiata* var. *australis* previously described. To Mr. J. D. Richards, Orchid grower to T. A. Tilley, Esq., Glednow, Leeds, for *Celoglyne cristata* var. *alba*, which differs only from the well-known type in the absence of yellow from the crest on the lip; to Mr. Boller, Kensal New Town, for *Mammillaria Caput-Meduse*, one of the peculiar globular-stemmed species thickly studded with little protuberances bearing a few whitish spines; and *Haworthia Bollerii*, a neat plant with spirally-arranged imbricated bronze-green triangular leaves. Floricultural certificates were awarded to Messrs. Veitch for *Hyacinths Magnificence* and *Primrose Perfection*; the former has a fine spike of large double light-blue bells, the other was described last week. *Azalea Roi Leopold alba*, a grand form of a well-known variety. The flowers are of medium size but excellent shape, white, with a few streaks of crimson, and produced in great profusion; and for the following Amaryllises:—*Storr's Beauty*.—A beautiful variety certificated last year by the Royal Horticultural Society; *Empress of India*.—Flowers large, of good form and very bright scarlet, the petals broad and of excellent substance; *Cecilia*.—Flowers of medium size, petals broad, banded transversely with crimson, tips and centre white; and *Madame Albani*, flowers very neat, streaked with rosy pink and white, a pretty variety. To Mr. H. B. Smith, Ealing Dean, for *Cyclamen Queen Victoria*, a handsome variety with very large pure white flowers, petals broad and rounded; habit vigorous. To Mr. H. Little for *Cyclamen Ruby Gem*, described last week; and to Messrs. Barr & Sugden, Covent Garden, for *Narcissus albo-aureus* with large double flowers, the outer petals very pale yellow, occasionally white, on the centre golden yellow.

**TEA ROSES.**—I have no wish to enter into the controversy originated by your correspondent "WYLD SAVAGE," but I would submit that it is very unusual for a member of a committee to write about what has taken place at their meetings. I have belonged and do belong to a great many, but I have always considered that unless authorised by the committee no one has a right to write about its proceedings. It would destroy all confidence, and effectually hinder useful work being done.—A COMMITTEEMAN.

MR. PETER FERGUSON of Monkwearmouth writes respecting the SIX MONTHS' WINTER—"We had our first fall of snow in this district on the 20th September, 1880, and more or less we have had snow ever since. At the time of writing (25th March) we are having heavy showers of snow every day, with sharp frosts at night. Gardening operations are a long time in arrears, but with brisk drying winds the land will soon be in a good workable condition."

— A MEETING of the ROYAL BOTANIC SOCIETY was held on Saturday the 26th inst., Mr. G. J. Symons, F.R.S., in the chair. Upon the table was exhibited a fine flowering specimen of *Erythroxylon Coca*, the "Coca" of South America, grown in the Society's greenhouse. Professor Bentley said that, although in this country little was known of it, in South America its consumption was calculated at 40,000,000 lbs. per annum, and by the natives considered as much a necessity of life as Tobacco in other countries. Marvellous tales are told of the power of Coca leaf in allaying hunger and stimulating and supporting the body in extraordinary exertions, more especially in that of climbing heights and travelling over mountainous districts.

— MR. W. BOWELL informs us that a LOQUAT (*ERIOTRYA JAPONICA*) in the gardens of Stawell House, Richmond, Surrey, has a fine crop of ripe fruit, comprising about a dozen bunches, each bunch composed of eight or ten beautiful fruits. The specimen may be inspected between 2 and 5 P.M. on application to Mr. Bowell.

— WRITING to us at the close of last week on the WEATHER IN THE MIDLANDS "A GARDENER" observes:—"Frost and snowstorms are the rule here, with a lowering barometer and cold east wind. Well, better now than later. We have scarcely anything green left in the garden; no Broccoli, nor in fact anything except Brussels Sprouts."

— WE have received the following PUBLICATIONS FROM MESSRS. CASSELL, PETTER, & GALPIN:—"Paxton's Flower Garden," part 8, with coloured plates of a very dark-coloured variety of *Bollea cœlestis* and flowering sprays of the double white and red Peach. Several woodcuts are also given in the "Gleanings." The accompanying letterpress gives both descriptive and cultural particulars. "Familiar Garden Flowers," part 26, has coloured plates of the Day Lily (*Hemerocallis flava*) and the Rosy Yarrow (*Achillea asplenifolia*), the former with some general notes on the *Hemerocallis*, history and culture; the principal Yarrow also receiving attention, as well as the one figured. "Familiar Wild Flowers," part 49, contains coloured plates of *Atropa Belladonna* and *Lysimachia vulgaris*, each accompanied by interesting historical notes. The third part of "Illustrated British Ballads" contains "The Beggar's Daughter of Bednall Green," "The Battle of Blenheim," "The Battle of Bothwell Bridge," and several others appropriately illustrated. This is likely to prove a very beautiful work.

— THE first annual EXHIBITION OF SPRING FLOWERS AT BIRMINGHAM will be held in the Town Hall on Easter Monday and Tuesday, April the 18th and 19th. In the fifty-eight classes provision is made for the majority of spring-flowering plants, including Hyacinths, Tulips, and other bulbs, Roses in pots, Deutzias, Spiræas, Dielytras, Azaleas, Epacrises, Cinerarias, Cyclamens, Primulas, Auriculas, miscellaneous stove and green-

house plants, and cut flowers. The prizes range in value from £1 5s. to 2s. Schedules and particulars may be obtained from Mr. C. Redfern, High Street, Birmingham.

— THERE has for some time past been a very extensive display of PRIMULAS AT MESSRS. CARTERS' NURSERIES AT PERRY HILL, but the flowers are fading now, fertilisation having been in great part effected and seed pods commenced forming. The plants are grown wholly for raising seed, hence the object has been to have them small and late instead of large and early, the seed setting more readily during the bright days of spring than the dull days of winter; but if the plants are small the flowers are large, of excellent form, and distinct colours, the whites smooth and pure, and the coloured varieties rich. For the purpose of preserving and improving the strain every plant at all faulty is promptly removed, only those of the best quality being retained for seed. Amongst the stock the "Blue Primula," of which much has been heard, is noticeable. The flowers, now fading, are purplish lilac, previously they were much deeper. This variety contains more of blue in its petals than any Primula in cultivation, and the flowers being good it is worthy of trial, as it may be the precursor of what many covet—a "true blue." When plants were exhibited the day was one of the most dismal and gloomy of the season—a great disadvantage to what many florists consider a decided novelty and a distinct "break" in the family to which it belongs. A deep purple form in the same house is also very telling. The plants referred to occupy a house upwards of 100 feet long and 14 feet wide, and as arranged in groups of the several colours the display has been highly imposing.

— MR. WM. THOMSON, of the Tweed Vineyard, recently communicated a letter to the *Scotsman* upon the WEATHER IN THE NORTH, in which he observes—"We are again, March 21st., in midwinter in this district. Yesterday, from noon till 6 P.M., we had a severe snowstorm. The snow melted as it fell for a time, but in the course of the afternoon the air became colder, and this morning we have 3 inches of snow on the ground, with 8° of frost. Thus, with two short intervals, we have had five months of frost and snow. On the 3rd of November we had 18° of frost, on the 20th 26°, on the 23rd 3° below zero, increasing in intensity till we had 10° below zero on January 17th. The only winters within my recollection that will compare with the present for severity are those of 1837-8, which was as long but not quite so severe, and 1878-9. The winter of 1879-80 had a short period of as intense frost in this district of Scotland, but it was not general, as it has been this winter. It was, however, much more severe in France, Belgium, and many parts of the continent. I think it is evident that no frost has been so destructive to vegetable life for 150 years as that of this and last winter, for I find that there are many Holly, Yew, and other trees killed that must have stood nearly two hundred years. One matter worthy of remark is, that where I have seen nearly all sorts of Hollies, Yews, Laurels, and even Rhododendrons killed, I have not seen a single Japanese evergreen even injured."

— MESSRS. BUTLER, McCULLOCH, & Co., of Covent Garden, have sent us a shilling box of flower seeds, containing twelve packets of seed of popular flowers. The box is very ingeniously constructed, and is admirably adapted for transmission through the post office.

— A CORRESPONDENT, "C. K.," sends us the following paragraph that he has cut from the *Daily News* on PLANTS BLOOMING WITHOUT EARTH, and would like to have further particulars on the subject. So should we; it savours of sensationalism at present.—"M. Alfred Dumesnil, a son-in-law of Jules Michelet and the Editor of the first edition of Edgar Quinet's works, claims to have

made an interesting and useful discovery—how to preserve plants in a perfectly vigorous state without any earth. Since November, 1880, the date at which his researches proved successful, he has, with the exception of a six-weeks stay in Paris, been continually taking plants from the ground and applying his process to them. Has never found the least interruption in their vegetative functions; on the contrary, winter and spring plants have blossomed with a vigour which, as an experienced horticulturist, he has never seen in his garden. With the shelter of a glass, Hellebores taken up at the end of November and the middle of December have remained from two and a half to three months in blossom. Other plants—Primroses, Daisies, Violets, Auriculas, &c.—have not only been in bloom for three months but have thrown out new buds. Bulbous roots, small shrubs, exotic plants, such as Azaleas and Cyclamens, take equally well to the process. M. Dumesnil exhibited some specimens of plants blooming without earth in the Square, Solvère in Rouen, last December; and at his home at Vascœuil, about fourteen miles from that city, anyone may have ocular demonstration of the results he has obtained."

### THE MOTH ORCHIDS.

(Continued from page 236.)

BEFORE describing the other chief species of this beautiful genus there are two modes of culture differing from those already noted which are worth attention. The first is employed almost exclusively for the *Phalænopses* and *Aerides* in Mr. Day's collection of Orchids, and in a few other gardens and nurseries, with very good results. A peculiar kind of cylindrical basket is used, constructed of small bars of teak a foot or more in length and an inch in diameter, connected by wires passed through them, and fixed at a regular distance apart—about a quarter of an inch, by small pieces of metal piping or other suitable material. An open cylindrical erect basket is thus formed; and to render it capable of holding the plants two bars of wood are secured about 4 or 5 inches from the base inside, crossing each other at right angles; upon these large potsherds are placed, filling up with smaller pieces to within 2 or 3 inches of the upper part of the basket. Sphagnum moss with a few small potsherds constitutes the medium in which the plants are grown, and as far as the *Phalænopsids* are concerned in the collection named above appears to be very satisfactory, for it could scarcely be desired to have plants in better condition or with finer flowers. The chief merits of these baskets are that there cannot be the slightest approach to stagnation about the roots of the plants, and they can be placed on a stage like pots or suspended from the roof. The former is, however, the better position, as they can be constructed of any height so as to raise the plants to the requisite distance from the glass. Plentiful supplies of water are needed, especially in the growing season, when it is not easy to give too much, as it passes away so readily; and if a suitable temperature and moisture are maintained the roots grow vigorously, clinging to the bars with considerable tenacity. Where these Orchids are thriving under any other system I would not advise a change, but if much difficulty is experienced with them the plan is well worth a trial, for it is very simple and has proved satisfactory wherever I have seen it employed. The second mode has not so much to recommend it, though it has been employed by a few experienced Orchid growers, but not with very encouraging results. The plants are secured to the side of a porous earthenware pot, which is kept filled with water, a small aperture near the bottom that is plugged with a cork permitting the ready changing of the water when needful. These pots are made with a flat side, so that they can be placed against a beam in any suitable position; but though the plants continue in most cases moderately healthy they are rather weak and flower very poorly.

Returning to the enumeration of principal species the first deserving attention is

*P. grandiflora*.—This is a remarkably handsome plant, and holds a foremost place in the estimation of all Orchid lovers. It resembles the beautiful *P. amabile* in the shape of the flowers, but they far surpass those of that species in size, and the lip is marked with yellow, whereas the same organ in *P. amabile* is tinged with rosy pink. The leaves, too, are of greater length and a lighter shade of green. It was, however, for a long time considered as merely a fine variety of *P. amabile*, and it was not until 1848 that Lindley separated it under the name now given. A good specimen of the plant exhibited by J. H. Schroder, Esq., of

Stratford Green, at a September meeting of the Royal Horticultural Society in the preceding year, and for which a silver Banksian medal was awarded, attracted much attention, and thus led to a more critical examination than had been previously accorded it. By some it is considered as the *P. amabile* first mentioned by Blume, for the species now known under the name is believed to be distinct from that originally referred to by him. It varies considerably in the size of the flowers and the depth of the yellow tint in the lip. The largest-flowered variety that I have seen was an extremely handsome plant, bearing fine branching spikes or panicles with blooms exceeding 5 inches in diameter; the sepals and petals of great substance, pure white and rounded; the lip having a few bright yellow streaks. One variety is named *aurea*, owing to the colouring of the lip being much darker and richer than usual. The species is a native of Java.

*P. intermedia*.—One of Mr. T. Lobb's introductions, and considered as intermediate between *P. amabile* and *P. rosea*, possibly what is termed a natural hybrid, several of which occur in the genus. It is not one of the most handsome, yet possesses an elegance of habit and contrast of rose and white in the flowers that render it a favourite with most growers. The leaves are light green; the flowers being of moderate size with neat white sepals and petals tinted with rose, and a small lip of a deep rosy purple hue. It is found in Manilla. One very beautiful variety is named *Portei*, which surpasses the species in the fine branching spikes bearing more numerous larger flowers, the colouring being similar, but the contrast of tint between the lip and other portion of the flower is more distinctly marked. It continues a long time in good condition, and is further noticeable for its large dark green handsome leaves, which have a purplish tinge on the lower surface, suggestive of *P. amabilis*. It is a native of the Philippines, whence it is said only two plants were first imported to this country several years ago, both of which were at one time in the Broomfield collection, and the plant is still rare both in cultivation and in a wild state. Another delicate pretty form is known as *Brymeriana*, and is chiefly distinguished by the lip being white and marked with crimson. It also is very rare.

*P. Lüddemanniana*.—This is an extremely distinct and beautiful species from the Philippines, which appeared in this country about fifteen years ago, but had been previously known on the continent, where the flowers were first produced on a plant in the possession of M. Lüddemann at Paris. With regard to its introduction to English cultivators, it appears to have been sent out from the Clapton nursery, where, owing to the general resemblance the plant bears to *P. rosea*, it was mistaken for that species, and sold under that name. Plants consequently came into the possession of several Orchid growers about the same time; and at the meeting of the Royal Horticultural Society on May 2nd, 1865, no less than four specimens were exhibited in flower, for which certificates were awarded—namely, by Dr. Pattison; Mr. Charles, gardener to Robert Burnett, Esq.; Mr. Pilcher, gardener to S. Rucker, Esq.; and Messrs. Low. The leaves are about 8 inches long, bright green; the flower spike often exceeding a foot in length, bearing neat compact flowers of medium size; the sepals and petals white barred transversely with brown towards the points, the lower portion being barred with violet purple; the lip rather long, and of a similar tint to the last-named. The markings remind one of the singular *Vanda Cathcarti*. It is unquestionably one of the most distinct and beautiful *Phalænopsids*, and, like others of its relatives, the flowers last for a long time. It is more readily increased than most of the genus, as young plants are frequently produced upon the old flower stems—a peculiar character which some other forms also possess, but not in such a marked degree.

*P. rosea*.—Another of Mr. T. Lobb's introductions from Manilla. A pretty species with rather small flowers, the sepals and petals white with a tinge of rose, the central lobe of the lip being purple, and the side lobes often tinted with dark yellow. The leaves are bright green, slightly tapering from the apex to the base, and the habit of the plant resembles some of the larger-flowered species, though not quite so vigorous. It is not often seen, and cannot by any means take a position with such forms as *P. amabilis*, *P. Schilleriana*, and *P. grandiflora* as regards beauty, though it has the excellent quality of remaining in bloom during many weeks.

*P. Mannii*.—This is well entitled to the attention of growers, as it is one of the best small-flowered *Phalænopsids* at present in cultivation. It is also remarkable for extending the geographical range of the genus into Assam, where it was found by M. Gustav Mann in 1868. Plants were subsequently introduced to England, but there are now very few specimens in cultivation, only being represented in some of the largest collections. The engraving was prepared from a plant in Mr. B. S. Williams's nursery, Upper Holloway, which flowered in one of the houses a few weeks since,

and was referred to on page 95. The leaves are of moderate breadth and bright green, the flowers being produced on spikes 9 inches or more in height. The sepals and petals are narrow, of a yellow ground colour, barred and spotted with reddish brown or pale chocolate; the lip is crescent-shaped and white; the flowers varying in size on different plants from 1 to 2 inches in diameter. The specimen shown was growing in a basket, and appeared in

excellent health, the leaves clean and strong, and the colours of the flowers distinct and bright. It is so very distinct in the form of the flowers from the better-known species that on casual observation it would be scarcely thought to belong to the genus *Phalaenopsis*, though the habit and foliage are more suggestive of the typical forms.

*P. cornu-cervi*.—An ally of the last-mentioned, but not quite so

Fig. 60.—*PHALAENOPSIS MANNII*.

attractive and rather difficult to grow, requiring a high temperature and abundance of water. The flowers are somewhat like those of *P. Mannii*, but there is a greenish tinge in the sepals and petals, and the blotches are of a duller colour, so that it is much less attractive, except when very well grown.

*P. Lowii*.—As regards its native habitat this is perhaps the most remarkable of the genus. It is said to grow upon exposed rocks in Moulmein, where at one time of the year the rains are

extremely heavy, and at another the heat and drought are so great the plant loses its leaves and appears to be almost dead, but revives with the return of the wet season and then makes its growth. Such conditions as these are not easily imitated, and in consequence the plant is rarely seen in satisfactory health. However, it is so attractive that most growers do not spare any attention to induce it to flower, when they are well repaid for their trouble. One of its chief requirements is a light position, and with careful

attention to the supply of water and the maintenance of a moderately high temperature success may be attained. The leaves are dark green, but not of quite such thick texture as most other species. The flowers are of medium size, very neat in form, with rounded white rose-tinted sepals and petals, and a bright rosy purple lip. The species was discovered by the Rev. C. S. P. Parish, and introduced several years ago.

The foregoing are some of the most beautiful Moth Orchids, but there are many others all more or less interesting which it is not necessary to describe at length. For instance, *P. sumatrana* has pretty flowers barred and blotched with reddish brown something like an *Odontoglossum*. *P. casta* with white flowers is regarded as a natural hybrid, under which category *P. leucorrhoda* is also included. The latter is considered as a hybrid between *P. Schilleriana* and *P. amabilis*, resembling the former in the leaves and the latter in the flowers. *P. Veitchiana* and *P. violacea* are also pretty species. Of the last an attractive variety, which has been named *Murtoniana* by Professor Reichenbach, was sent to this country a few years ago by a friend of mine, Mr. H. Murton, Superintendent of the Singapore Botanic Garden, and a specimen flowered at a garden in Cornwall. The flowers are light yellow tinged with purple on the sepals and at the base of the column. *P. amethystina* is another elegant species, but not so showy as most of those described, all of which are well worth growing where there is the necessary accommodation, though *P. amabile*, *P. Schilleriana*, and *P. grandiflora* are represented in nearly every collection.—L. C.

#### FRUIT HOUSES.

*Vines*.—Late varieties started at the beginning of the month will now be moving, and should be syringed freely several times a day, closing the house with a humid atmosphere at 75°, affording a night temperature of 55° to 60°, and 10° to 15° more by day. Syringe the Vines morning and afternoon until the bunches are showing, when it must be discontinued, securing a humid atmosphere by damping the paths, walls, and borders frequently during the day. Any late varieties, also Muscats, must be started at once. Give the inside borders a thorough soaking with water at 90°, and syringe the rods twice a day, maintaining a humid atmosphere by damping the paths, &c., several times a day. To secure an even break bring down the rods of young canes to a horizontal position until all the eyes have started, when they may be tied up to the wires. The night temperature should be maintained at 55° to 60° at night, and 10° more by day, closing at 75° with a humid atmosphere. Houses of Hamburgs for use late in the year should be kept as cool as possible, admitting air freely day and night except when frost prevails, during which time fire heat will be necessary to exclude frost and secure sturdy growth. By the middle of April they will be growing, and must have fire heat to maintain a night temperature of 50° to 55°, and 5° to 10° rise by day. Attend to disbudding, tying out, and stopping in succession houses, and keep the thinning of bunches and berries well forward. No particular rule can be laid down for thinning, as the several varieties differ in form and size of berry and bunch. In a properly thinned bunch every berry should have room to swell without being squeezed, and yet be so close as to preserve the form of the bunch when cut. Hamburgs and other free-setting varieties may be thinned as soon as out of flower, but Muscats and other shy setters should not be thinned until the properly fertilised berries take the lead. Where Grapes are thinned a temperature of 65° at night, or a few degrees more in mild weather, advancing early in the day to 75°, will be advantageous, ventilating from 75°, and maintaining the temperature through the day at 80° to 85° with sun heat, closing early and allowing an advance to 90° with plenty of atmospheric moisture. Keep up a steady circulation of dry warm air in houses where the Vines are flowering, with a minimum temperature of 65° for Black Hamburgs, and 5° more for Muscats. The bunches of Muscats should be brushed over with a large camel's-hair brush when in flower to assist fertilisation. Water all internal borders

requiring it with weak liquid manure, or sprinkle with guano and wash-in with water at 80° to 85°. The fermenting material should ere this have been removed from inside early houses, giving the border a thorough soaking with liquid manure, and mulch with short dung about 2 inches thick. Gradually reduce the atmospheric moisture where Grapes are ripening, and admit a steady circulation of warm air both day and night. Afford plentiful supplies of liquid manure to pot Vines with fruit swelling off, and if the roots extend from the pots into fermenting materials give a supply there as well.

*Melons*.—The first batch of plants will ere this have set or be setting fruit on the first laterals. During the setting a drier atmosphere and drier condition at the roots are necessary, with a few degrees higher temperature both by day and night. Be careful to have three or four blooms open at a time before impregnation, as it is important that all the fruit on a plant be of a simultaneous stage of growth, as if one or two take the lead the others will not succeed. If this occur the fruit taking the lead should be removed unless very early fruit is desired. Directly the fruits begin swelling give the beds a good soaking with tepid weak liquid manure, and place some rich compost previously warmed over the roots, ramming it well down. Maintain a good moisture by damping available surfaces occasionally, and syringe moderately about three o'clock on bright warm afternoons. Do not allow the foliage to become overcrowded, but by frequent stopping and thinning fully expose the principal foliage to light. Place supports for the fruit before they become too heavy. Continue the treatment to later plants advised in former calendars, employing more moisture as the days lengthen and the sun becomes more powerful. Pits and frames where the bottom heat is declining will require thick linings, and careful watching afterwards to allow the escape of rank steam. Avoid overcrowding the foliage, remove every alternate lateral, and keep the collar of the plant clear of foliage, and apply a little quicklime as a preventive of canker. Stop the principal growths a foot from the sides of the frame or pit. If no fruit appear on the laterals at the second or third joint pinch out their points, which will cause them to break, and fruit will then show plentifully. Fertilise the pistillate flowers daily as they become fully expanded, and pinch out the point of the shoot one joint beyond the fruit. When three or four fruits on a plant are set and swelling remove all others as well as any flowers, and attend frequently to stopping and thinning the shoots, watering with tepid water, earthing up the roots, and closing early in the afternoon, sprinkling overhead at the same time when bright. Employ good thick night coverings, watching for slugs and canker at the collar. A few brewers' grains laid at night form a capital trap for the former, and quicklime is the remedy for the latter. Sow for succession and pot off seedlings, keeping them near the glass to insure sturdy growth.

*Cucumbers*.—Plants that have been in bearing through the autumn and winter will need to be renovated at the roots. Remove with a hand fork as much of the exhausted soil as is possible without much injury to the roots, and give some rich lumpy compost previously warmed; press it down firmly, and shade for an hour or two at midday if the sun be powerful. An increase of sun heat necessitates additional vigilance, and if the plants are in good health there will be abundant growth, but otherwise the foliage will flag severely. Either the root action is inert or the night temperature has been kept too high, producing weak growth and thin-textured foliage. If the ill condition of the roots result from worms having possession of the soil expel them by repeated soakings of lime water, a small handful of lime being ample for three gallons of water, and to prevent flagging shade with thin canvas for an hour or two at midday. Healthy plants will hardly need shading at present, but the blinds should be prepared, thin canvas being most suitable. Repeated applications of liquid manure may now be given, always applying it in a weak state, and damp available surfaces in the house at closing time, keeping the evaporation troughs filled with guano water. Damp the house at 7 A.M., and syringe gently overhead at 3 P.M. on warm sunny days, closing the house at the same time. Attend frequently to thinning the foliage and stopping the shoots at one or two joints beyond the fruit. Keep a good degree of heat in pits and frames by the application or renewal of linings. Train and peg out

the growths, and apply water moderately at present as the nights are still cold, employing good night coverings.

## NOTES ON VILLA AND SUBURBAN GARDENING.

### KITCHEN GARDEN.

THE fine weather recently experienced dried the ground sufficiently for sowing Onions, Parsnips, Peas, Turnips, early Carrots, Asparagus, Leeks, Parsley, and Spinach. Onions succeed on a well-manured firm soil, and may be sown in drills 10 or 12 inches apart and left thicker in the rows. Autumn-sown Onions ought also to have been transplanted. These are disposed in shallow drills 10 inches apart and 5 inches asunder in the rows. If large bulbs are required place the rows 12 inches apart. It is yet too early to sow the main crop of Carrots, but a few may be sown on a warm border. Give the preference to light unmanured soil; sow thinly in drills 10 inches apart, and between these sow a line of Radishes: either Early Horn or Nantes Horn Carrots are suitable; and good early Radishes are Wood's Frame and the French Breakfast. A mixture of equal parts of soot, lime, and wood ashes thinly distributed over the surface of the soil and lightly stirred in prior to sowing will prove beneficial, and a good preventive of the maggot so destructive to Onions and Carrots. Where the maggot has proved very injurious a small quantity of wood ashes should be sown in the drills with the seed. Ground deeply dug and manured with lime only is most suitable for Parsnips; the seed may yet be sown in rows from 15 to 18 inches apart. Early Turnips are best obtained on an east border. The soil should be made firm and not be very poor. Sow thinly in lines 15 inches apart. Asparagus may be sown in drills 12 or 15 inches apart, and the seedlings can be transplanted in the next or following season. A pinch of Leek seed to be sown thinly broadcast or in shallow drills in order to obtain plants for putting out later on. Parsley may be sown in any narrow border, but is much finer if given an open position and the plants freely thinned out.

Peas reared in boxes under glass should be transplanted before becoming drawn. If sown in fine soil and evenly over the boxes, shake the roots clear of the soil, having first cut out deep narrow drills with a spade, and lay them in to their full depth. Those sown in turves or pots to be transplanted as raised. The rows of Peas to be from 30 inches to 1 yard apart, and when first put out should be lightly protected. Nearly dead Spruce Fir boughs are most suitable, as these need not be removed when the stakes are put in. If not already in no time should be lost before making a good sowing of early Peas. As soon as the earliest sown are pushing through the surface sow more of William I. or other good early variety in the open ground, and at the same time a row of a good second early variety, such as Alpha, Hair's Dwarf Mammoth, Nelson's Vanguard, and Laxton's Supreme—medium height varieties—to be staked or otherwise. Taller varieties suitable for this sowing are Culverwell's Telegraph, Carters' Telephone, and Huntingdonian. Spinach to be sown between the rows. A mixture of soot and lime dusted over the young growth of Peas will tend to keep off the birds.

Autumn-sown Lettuces wintered in frames if well hardened off may be transplanted to a warm border. Manure the ground freely and give the plants good room. The rows of Cabbage varieties to be 9 inches apart and 6 inches asunder in the rows, and the Cos varieties 1 foot apart and 9 inches asunder in the rows. Sow more seed of Paris White Cos, or varieties of the same on a warm border, and a pinch of the All-the-Year-Round Cabbage Lettuce. Seed of Dwarf Erfurt Mammoth or other early variety of Cauliflower, Veitch's Autumn Giant Cauliflower, Brussels Sprouts, Cabbage if required during the summer, Early Ulm and Little Pixie Savoy if required early, may be sown thinly on a sheltered border.

Early Potatoes may be planted at the foot of a warm wall or on a sheltered border. A light sandy soil is best for this crop, and when planting rub off all side shoots and carefully draw the earth so as to preserve the central sprout. Do not hurry in the planting of principal crops, preferring rather to have the sets in good condition and the ground in good working order.

### HOTBEDS.

It is not too late to form what has been before termed a "spring

bed." This may consist of leaves and stable manure previously prepared, or leaves previously used for forcing. Seakale or Rhubarb, to which is added a little somewhat fresh stable manure. The bed may be about 3 feet in depth and of any width, and be made firm. About 6 inches of fine sandy or light soil to be placed on the surface, this to be kept in position by narrow boards, the latter being fixed by tall stakes, which also support the fish netting and other protecting material it may be found necessary to use. One corner may be used for repeated sowings of Mustard and Cress, and in another may be sown a pinch of Celery for the earliest crop. Seed of an early Carrot might be sown thinly over the remainder of the bed, and with this may be sown patches of early Radishes, Cauliflowers, Brussels Sprouts, Lettuces, and even Asters and Stocks. Thin sowing must be strictly practised, and each kind should be removed, to be pricked out or otherwise before they overgrow their neighbours. The Carrots will eventually have sole possession of the bed, and these alone will well repay for the outlay and trouble taken. By sowing on a "spring bed" seed is economised, and crops are obtained much earlier than if sown on an ordinary sheltered border.

### GREENHOUSES.

*Ferns.*—Many kinds of these, notably the Adiantums or Maiden-hair Ferns, are commencing growth and may be repotted. When in this stage of growth the balls of soil may be reduced considerably with the help of a sharp-pointed stake, the roots lightly trimmed, and be repotted into a pot of the same size as that previously used, or somewhat larger. They may now be safely divided if more plants are wanted, using for this purpose a plunging fork in preference to cutting through with a knife or spade. Use pots as small as possible, and do not supply water for a week at the least. Adiantum formosum should not be disturbed at the roots unless dividing is resorted to in order to increase the stock. The varieties of Pteris, Blechnums, Aspleniums, Nephrolepis, and others may all be slightly reduced and repotted. Any that are sickly should have the greater part of the old soil removed from the roots, trimming these with a knife and returning to as small pots as can conveniently be used. Soil suitable for all the foregoing may consist of equal parts of turfy loam and peat, with a liberal addition of sharp sand and charcoal. If either the loam or peat are bad use less of these; a quantity of leaf soil and broken potsherds may be substituted for the charcoal. All pots to be cleaned and well drained; covering the crocks with moss, and over this a layer of the roughest soil. When the plants are repotted place them in a warm part of the house out of draughts, shade from bright sunshine, and supply water carefully.

## THE BEE-KEEPER.

### A RETROSPECT.

NOTWITHSTANDING the many unfavourable seasons for bees during the last ten years, two of which were very destructive of bee-life, killing, I daresay, eight-tenths of the swarms in the midland and northern counties of England, great advancement has been made in apian science and practice. Prior to 1870 little progress had been made in England for forty years. Things are different now: knowledge is spreading fast; gifted teachers and successful apiarians are at work, and doing much good by their lessons and example. What is most wanted is a good season or two for honey-gathering throughout all the counties of England. It would be painful to mention the disappointments and losses of many people, both young and old, who have made unsuccessful attempts to begin bee-keeping within the last few years. Baffled by unfavourable seasons, failure has been the result in the case of many hopeful beginners. The straw hive, the bar-frame, and the Stewarton have all been tried and found wanting. The weather, more than anything else, has caused the depression and failures. Some years ago a clergyman from Scotland, being in this locality, called to have a chat about bees. He had made a commencement two years previously, and had not then a spoonful of honey. Since that time the Scottish bee-keepers have had three good seasons for honey, and probably the clergyman's ill luck at first is now forgotten in the encouraging success of after years. While lamenting the disappointments and collapses of many in their first

attempts in bee-keeping, and while battling ourselves against adverse winds and seasons, I have never lost hope that good times will come to the apiarians of England. It is well for people who are doing what they can to surmount the difficulties of life to remember the sentiment and kindly advice of two well-known mottoes, "Nil desperandum," and "Wait a wee, and dinna weary." Thomas Carlyle once said, in speaking of hope, that "from the lowest depths there is a path to the loftiest heights." And some other writer says, "Hope is a vigorous principle, animating man to do his utmost; and thus by perpetually pushing and assurance it puts difficulty out of countenance, and makes seeming impossibilities give way."

During the last ten years the moveable-comb hive has received great attention. Enlargements have been made, and it has been found that protection from cold in winter is necessary, or at least beneficial. Hence frame hives with cavity walls are now used and recommended by the advanced men of the bar-frame school, and which, doubtless, will gradually be adopted and used by all classes of this school. As improvements have been made in the moveable-comb hive, and as its mode of management is becoming better understood, there is good reason to expect that more satisfactory results will come from its use in the future than in the past. Amateurs of this school will in the good seasons be encouraged by success. It may be fairly stated that the machinery of bee-keeping to a large extent is now prepared for work, and awaits only the return of honey weather.

During the past twelve months nothing of special importance has transpired amongst apiarians of Great Britain, except the prodigious harvests of honey in Scotland. I can think of no discoveries that have been made in the habits of bees or in the practice of managing them. Much has been said about foul brood, and speculations have been rife as to its origin, character, spread, and cure. I think I have read all that has been written in English on this subject, and I have to confess that my opinion remains undisturbed and unchanged as to the incurability of this terrible disease—that nothing will save the bees of an infected hive but their removal from it. Last year a novel idea was mooted. A writer recommended his readers to use watery syrup in feeding bees, in order to prevent them from going out for water in inclement weather, and he told them if they do so the lives of many bees would be saved. If I remember rightly, from one to two pints of water is to be mixed or given to one pound of sugar. Now one pint of water to one pound of sugar is very good and acceptable food for bees at all seasons, and if used in quantity in inclement weather it would cause the bees to breed and send them abroad for water, the very thing the writer wants to prevent. Such haphazard opinions and recommendation are novel enough, and that is all that can be said in their favour.

Another idea is being mooted now—viz., that bees eat honey in order to keep themselves warm; that is to say, if I understand the theory rightly, that bees eat more honey in cold weather than they do in warm weather, and that this extra consumption of food is for the production of heat. I remember a shrewd expression of Mr. Moses Quinby—viz., that his bees acted differently from those of other people, meaning thereby that from his experience amongst bees he could not support or confirm statements made by other writers. If it is usual for bees to eat more honey in cold weather than they do in warm weather I have been misled by my bees for fifty years, for I have found that bees consume more honey in mild autumns and mild winters than they do in cold ones—nay, that the consumption increases with the heat of the hives or the warmth of the atmosphere around them, and that the consumption decreases with decreasing heat or warmth. By removing a hive from its outdoor quarters into a greenhouse during winter, I invariably find that the bees eat more honey than those out of doors. Strong hives or stocks consume about 15 lbs. of honey each from September to March in mild winters, whereas 10 lbs. will serve them in cold winters. Bees are nearly motionless in cold wintry weather, and in this condition they neither require nor use much food.

Once more let me return to the question of crude and perfect honey. "B. & W." was asked what kind of proof he wanted that bees convert honey crude into perfect honey. Instead of complying with this request, he now admits that there is a difference between crude and perfect honey, and tries to account for the change in another way. He says "that it seems to be the most easily accountable thing in the world. I am fully convinced that evaporation is the chief and perhaps the sole factor in the business, although it is, of course, possible that the bees may themselves reject much of the honey they have too hurriedly collected (not that we hold such an opinion) during the excitement of the period of glut, and there may be (probably there is) some chemical change perpetually going on, owing to the high temperature of the hive,

which affects the consistency of the honey and even its quality." This is the language of uncertainty, showing that the writer is in a thicket of doubts and cannot well disentangle himself. I respectfully submit that it would be better for "B. & W." to abstain from offering criticisms on the subject till he is able by fact and argument to support his theory. I am not going to argue the matter further, but simply say that if I live till the honey season arrives, I will before witnesses take a bottle of crude and a bottle of perfect honey from a hive, and request permission to forward the same to the British Bee-Keepers' Association for its decision as to whether crude honey can be converted into proper honey by evaporation. Will the evidence of eight or ten of the leading apiarians of Great Britain satisfy our friend?—A. PETTIGREW.

#### AMERICAN BEE JOURNAL.

THE "American Bee Journal" after a well-deserved successful run of twenty years passes into its seventeenth volume as a weekly, in which form several numbers have appeared. It occupies thus a unique position, which its acknowledged merit will, we hope and believe, enable it to sustain with increasing advantage to itself and the bee-keeping world generally. Several of its correspondents are men of marked ability, while its excellent editor, Mr. T. G. Newman, needs neither introduction nor commendation, since he was with us during a portion of last summer. Amongst a long list of subjects treated a few will be especially interesting, such as

#### FERTILISATION IN CONFINEMENT.

Professor Hasbrouck has experimented upon this matter as he says with success, his plan being in short this. He cuts a square opening into a sugar barrel, and into this fixes a sheet of glass, and then tubs the queen (she being of the right age), with a number of selected drones. They fly together under the glass and accouplement takes place. This experiment has been tried again and again in other apiaries with uniform failure, and not a few have supposed that anxiety to obtain a certain result has interfered with accuracy of observation. This interesting question which has so much to do with the production of a superior race of bees, besides, if we reach easy and tolerably uniform success in it, being an enormous assistance in requeening colonies, is exercising the minds of many progressive American apiculturists. Amongst these Mr. G. W. Demaree writes—

"In the month of August last I made what I called a fertilising cage, provided with a steep glass roof. Thus prepared, I watched for a virgin queen, and when she came out to take her bridal trip I captured her and placed her in the cage, which was set on top of the hive.

"First one drone and then another till a half dozen or more were put into the cage. The queen appeared to take her confinement quietly; inflated to the fullest extent she showed her beauty to the best advantage. If you would see a virgin queen in all her glory you must look at her when out on her heyday spree. The queen and drones flew lively in the cage, but the latter would do nothing but beat their cowardly heads against the glass roof, unconscious of the presence of the queen. After well-nigh baking myself in the hot sun I gave it up and returned the queen to her hive.

"*Second Experiment and Failure.*—The next day I proceeded to try the following experiment in hopes of throwing some light on the subject. I procured a long pole 16 feet long, to one end of which I nailed a strip of wood about 4 feet in length at right angles with the pole. Armed with a fine thread 4 or 5 feet long I watched for the queen, and when she came out I caught her, and by the aid of the deft fingers of Mrs. D., one end of the thread was made to span the delicate waist of her royal highness, the loop being provided with a knot to prevent it from cramping her waist—a performance, by the way, that required no little skill. Thus cabled, her wings and limbs were left free from incumbrance. The thread was now tied to the end of the transverse bar aforesaid, and the pole hoisted a few rods from the apiary. The queen performed nicely at the end of the thread. There were plenty of drones flying, and soon (I should think in two minutes' time) the air was black with drones circling about the fettered queen. Now and then one of them would give her chase, but when the thread would bring her to a sudden halt he would dart to one side and disappear. Several times a drone struck her with considerable force, but would bound away as though suddenly frightened. I watched the proceedings closely, till the queen became weary and the drones retired. The experiment proved a failure as to the fertilisation of the queen, which I attributed to the fact that the queen was somewhat injured by catching hold of a tuft of grass when the pole was being elevated.

"*What the Experiment Suggested.*—It is evident from what I saw in connection with this experiment that a great number of drones follow the queen when flirting through the air while out on her heyday spree, and perhaps the swiftest cavalier of them all overtakes and is accepted by her. Thus it would appear that Nature in this way selects the swiftest specimens of the race to propagate the species.

If this is not mere "theory," it goes very far to show why Nature has provided so many males in comparison with the number of developed females, and why the latter must take the risk of fertilisation in the open air.

"I gave much time last season to the study of this subject, and I find that a well-developed virgin queen plies her wings with lightning velocity, and flies with wonderful rapidity. Now, if she does not give chase to the drones, how are we to account for the fact that she usually makes three or more trips into the air when drones are plenty? I saw one beautiful slender little princess make sixteen trips before she was caught by a drone. When she returned for the last time, having been gone twenty-two minutes, she fell short of the entrance of the hive, like a worker bee overloaded with honey and pollen. Three days later she was laying.

"If Nature has determined that the 'race is to the swift' as pertains to the propagation of the honey bee, then perhaps Nature will forbid the interference of the wisdom of man in this matter—or, in other words, fertilisation in confinement will never be a success."—FRANK R. CHESHIRE, *Avenue House, Acton.*

(To be continued.)

### TRADE CATALOGUES RECEIVED.

Rawlings Brothers, Romford, Essex.—*Descriptive Catalogue of Dahlias.*

The Native Guano Company (Limited), Aylesbury, Bucks.—*Price List and Testimonials.*

Ewing & Company, Newmarket Road, Eaton, near Norwich.—*List of New Roses for 1881.*

\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**The Gooseberry Caterpillar** (*K. K.*).—We are obliged to you for your letter, which shall be inserted in a future issue, with the notes and figures to which you refer.

**Covering Stove Walls** (*F. R.*).—We insert your letter in order that our correspondent and others who have tried the plan described on the page quoted may reply: "I shall be glad to know whether the suggestions on page 227 of last week's Journal for covering walls in stoves will not have the drawback of making the wall damp, which, in the case of a lean-to against a house, would be injurious."

**Cinerarias** (*W. Wells, Redhill*).—The flowers are of great size, some of them being 3 inches in diameter, and the blue selfs are very clear and bright. As the plants are of dwarf habit with large foliage, they will be effective for conservatory decoration, but the florets are far too thin and pointed to be adjudged good from a florist's standard. If by crossing and selection you can obtain circular flowers of the same size of those before us, with stout overlapping florets, you will have a very fine strain.

**Yellow Roses** (*C. F. F.*).—The spray of No. 1 was not sufficient to show the character of the variety. We, however, submitted the blooms to Mr. D'Ombrian, who has grown the variety for many years, and he thinks both of the Roses are correctly named, "but Cloth of Gold is easily recognised. Its footstalks are much stouter than those of Maréchal Niel, and consequently the flower stands upright instead of drooping its head, and its foliage and habit are quite different."

**Grafting** (*W. B., Dorking*).—The examples you have sent are correct in principle, but we advise you to make the slices half as long again, and on the stocks a trifle deeper. Your knife must be very sharp, and the "cuts" true and smooth. If the scion is smaller than the stock the bark must meet on one side, when a union will be effected. You had tied them fully too tightly, still they must be made perfectly secure and immovable.

**American Plant Protector** (*H. S. Easty*).—We are not aware that it is sold in this country, but you may readily make some of any required size with light wood and tiffany that will answer your purpose. Tiffany protectors have long been in use in England, and in some nurseries have been extensively employed for sheltering plants from spring frosts. If the tiffany is dressed as follows it will be rendered waterproof, while the light will not be impeded. Take pale linseed oil 3 pints, sugar of lead 1 oz., and white rosin 4 oz.; grind the sugar of lead with a little of the oil, then add the rest and the rosin. Stir the whole well together in a large iron pot over a gentle fire. Tack the tiffany loosely on the frame, and apply the mixture while hot with a large brush.

**Planting Succulents** (*J. S. W.*).—It would not be safe to plant *Kleinias* now, nor yet *Echeverias*. Cannot you plant them temporarily near the shelter of a wall, and where you can afford protection against heavy rains and frost? The space they now occupy could then be utilised by other plants of a more tender nature. *Echeveria tabulaeformis* is not hardy, and must be wintered under glass, where it can be kept rather dry and safe from frost.

**Grapes Withering** (*R. Davies*).—You afford us no data whatever to enable us to suggest the cause of the bunches shrivelling. We shall require to know in what position the vines are in the house, and the temperature that has been maintained; also what you have, or have had, under the vines where the

bunches are affected, and any other particulars that will guide us in the matter. A bare statement of a fact is totally insufficient in a case of this kind, and the conditions under which the vines are grown cannot be too carefully detailed.

**Propagating Honeysuckles** (*Idem*).—Cuttings of wood when nearly ripe will strike if inserted in a shady border in the autumn and duly watered. With the aid of a handlight and sandy soil they strike more readily. The most successful mode, however, of propagating is by layers pegged in moist soil in the autumn when the leaves commence falling.

**Cereus flagelliformis Unhealthy** (*A. A.*).—No doubt the plant has been injured by frost. The pieces you sent are quite dead, but if the points of the shoots remaining on the plant are still alive cut them off and insert them as cuttings in a mixture of finely broken brick rubbish, sand, and a little loam. Place the pot in a warm position, and do not supply any water for a week or two, afterwards supplying it in very moderate quantities. When the young plants commence growing they may be potted in a light porous soil, and placed in a sunny portion of the house after they have recovered from the potting. If you desire to keep them in an unheated structure during the winter remove them some distance from the glass, giving no water during frost, and afford some protection—a piece of paper placed over the plant will be sufficient, except in very severe weather.

**Pereskias for Stocks** (*Puddle*).—Your plants are not strong enough for grafting; but if you grow them well this year, stopping them a foot above the point where you intend grafting, to increase their strength, they will be in good condition for your purpose next spring.

**Aloe variegata Unhealthy** (*Idem*).—The root action of your plant is defective; perhaps it has been overpotted, or possibly overwatered. A pot 4 inches in diameter will be large enough for such a plant as you describe, and suitable soil is turfy loam with a liberal admixture of charcoal and crushed bricks, a little lime rubbish not being objectionable. The pots must be efficiently drained, water being applied cautiously until the roots are active, then more copiously as the summer advances, decreasing the supply towards the autumn, and keeping the soil moderately dry throughout the winter.

**Culture of Erythrina Crista-galli** (*J. H.*).—The shoots of last year will have been cut back to the eyes at their base. Early in March the buds will begin to swell, when the plants should be turned out of the pots, and, removing all or most of the old soil, return them to the same size of pot, employing a compost of sandy fibrous loam and sandy peat in equal parts, and a third of leaf soil, old cow dung, and silver sand, affording good drainage. Place them in a house where there is moderate heat, as that of a vinery or pit, and they will soon start freely, and should have a position near the glass, free ventilation, and be freely syringed. After May they do best in a cold pit, kept rather close, and closed early, so as to have a good heat. If you could give the plants after potting the benefit of a hotbed for about three weeks, so as to have the roots active before the tops are excited, all the better. Shift the plants into larger pots as required, watering with weak liquid manure after the flowers show; or they may be planted in a warm position in the garden. It is called the Coral Plant, and the flowers are very beautiful.

**Globe Amaranth Culture** (*Idem*).—The seed should be sown in a compost of loam, peat, and sand, the pots being placed in a Cucumber frame or other structure where a night temperature of 65° is maintained. When the seedlings appear place the pots near the glass to keep the plants sturdy. As soon as large enough pot them, placing them either singly or in threes in 3-inch pots, keeping them near the glass in a warm house or frame. As soon as roots are seen protruding through the drainage shift into 5-inch pots, employing a richer compost, and grow them for a time under the same conditions as before. During summer they succeed well in pits or frames heated by sun heat alone provided care is exercised in ventilating and watering, and the frames are closed early in the afternoon with moisture. The dwarf variety when well grown is very attractive. You had better pot a few more plants than you require for flowering, as a portion of them may not grow satisfactorily, being rather prone to wither in a young state; the roots must not be seriously disturbed when potting is done.

**Paying Prize Money** (*J. R. S.*).—We know that some of the prize money of the Royal Botanic Society's shows held last year has been paid, and if any is due to you you had better write to the Secretary. The Peach you name has large flowers.

**Small Fruits** (*J. E.*).—We do not know a work such as you name. Our "Fruit Gardening for the Many," post free 4½d., contains practical information on the culture of small fruits. "Fruit-Growing," by Canou Lee, published at this office, post free 1s. 6d., is also worthy of your attention. We have received a new American work on small fruits that we shall review shortly. It contains much that is interesting on the history of the Strawberry and the different species.

**Belladonna and Guernsey Lilies not Flowering** (*James Carter and Co.*).—Without knowing when the bulbs were potted, and the mode of culture that was pursued, we are unable to state the reason of their not flowering. The bulbs of the Belladonna Lily are undoubtedly very fine, and those of the Guernsey Lily of full average size, and that they were sound is evident by their healthy roots and luxuriant foliage. Even under the best treatment there is always a number of bulbs more or less large that do not flower when forced, and starting them too quickly is a frequent source of failure. It is important, too, that they be potted as soon as possible after their arrival in England. The habit of delaying purchasing the bulbs until late in the season, and then placing them in heat to "make up for lost time," is a mistake, and usually ends in flowerless plants.

**Cocoa-nut Fibre Refuse** (*A. D., Isle of Man*).—We presume you did not read our last volume, or you would have seen the uses to which this substance is applied. If you turn to page 365, October 21st, 1880, and page 458, November 18th of the same year, you will find the subject fully treated. If you do not possess those numbers you can have them in return for 7d. in postage stamps sent to the publisher, with the request that he send you Nos. 17 and 21 of the new series.

**Rippingille's Propagating Frame** (*Idem*).—Rightly used we consider this a useful appliance. It should be placed in a greenhouse or other structure, a temperature of 65° to 75° being maintained in the frame for ordinary propagating purposes at this period of the year. Water must be kept in the tray, but "how often it should be replenished" depends entirely on the amount of heat that is afforded to effect its evaporation. The lamps should be trimmed daily. We think the vendors of the frame supply particulars for its management. A little ventilation will be needed, especially early in the morning, to permit the escape of superfluous moisture. If placed in a cold house the frame may advantageously be covered with a cloth at night if any difficulty is found in maintaining the requisite temperature with the aid of the lamp alone.

**Roses in Pots Dying** (W. R. R.).—By your request your letter was forwarded to Mr. William Taylor, who replies:—"The solution of your mystery is as follows: Gloire de Dijon is not a good forcer till the plants are considerably older than yours, and have made some quite hard wood which can be cut back like a Hybrid Perpetual. Alba Rosea likes heat, and its flowers will not come a good colour without it. Your Gloires would not have died with the low temperature, and your Alba Roseas probably would not have done so well. Even outdoors Gloire de Dijon does not like much heat; it does best on the north side of a building—at least, that is my experience in one of the southern counties. Young plants such as yours should not be allowed to become dry during winter; the most robust under such conditions would be the first to succumb."

**Pruning Gooseberries** (Ignoramus).—Early spring is a good time for pruning Gooseberry bushes, just as the buds are showing signs of swelling. We have, however, pruned them successfully in the autumn where small birds, such as bullfinches and sparrows, did not abound to peck out the buds. Where these birds are destructive spring pruning is the safest course to adopt. We have seen bushes pruned when they assumed a green tinge from the advancing growth, and no injury resulted. The mode of pruning depends greatly on the age and character of the bushes. If they have been neglected for some years severe pruning is not advisable, as the branches in the interior are destitute of spurs, but if the branches are furnished with fruit buds these must have light and air. Our "Fruit Gardening for the Many," post free 4d., contains instructions on the subject; but if you want more specific information, and will send us the particulars we have indicated pertaining to your trees, we will endeavour to supply it. Brief notes on pruning Gooseberries appeared on pages 53 and 75 of our issue of January the 20th and 27th of the present volume.

**Layering Roses** (Rus).—If we decipher your hurriedly written post-card correctly, you require information on the above subject. We extract the following from "Rivers' Rose Amateur's Guide." If any of our readers can detail a better mode of procedure we will readily publish it. "About the middle of July, in most seasons, the shoots will be found about 18 inches or 2 feet in length; from these, two-thirds of their length, the leaves should be cut off close to the shoot, beginning at the base, with a very sharp knife; the shoot must then be brought to the ground, so as to be able to judge in what place the hole must be made to receive it; this may be made large enough to hold a quarter of a peck of compost: in heavy and retentive soils this should be rotten dung and pit sand in equal quantities, well mixed. The shoot must then be 'tongued'—i.e. the knife introduced just below a bud, and brought upwards, so as to cut about half way through; this must be done at the side or back of the shoot (not by any means at the front or in the bend), so that the tongue does not close; to make this certain a small piece of glass or thin earthenware may be introduced to keep it open. Much nicety is required to have the tongue at the upper part of the shoot, so as not to be in the part which forms the bow, as it is of consequence that it should be within 2 inches of the surface, so as to feel the effects of the atmospheric heat; unless this is attended to the roots will not be emitted quickly; the tongued part must be placed in the centre of the compost, and a moderate-sized stone put on the surface of the ground to keep the layer in its place. The first week in November the layers must be taken from the parent plant, and either potted as required or planted out where they are to remain. Those shoots not long enough in July and August may be layered in October, when the layers are taken from the stools; and, if any are forgotten, February and March will be the most favourable months for the operation. As a general rule July is the most proper season."

**Young Gardeners** (W. Yates).—The subject was fully discussed in vol. xxxvi., and many letters from head and under gardeners were published highly creditable to both. In our experience, which is considerable, we have noticed that as a rule if an under gardener is diligent, attentive, and industrious, and discharges his duties with care and intelligence, being at the same time civil and obliging to all, he usually commands the respect of his superior, and is trusted by him when his trustworthiness has been proved. Head gardeners know the value of such men, and do not studiously make them uncomfortable. At the same time we know that some gardeners are "hard to please," and these are often the best teachers. Passing lightly over mistakes is not true kindness. We know some of the best gardeners of the day who in their probationary career considered themselves harshly treated, and felt at the time they were serving the hardest of taskmasters; but now they are thankful for the habits of punctuality and of attention to small details that were enforced, and which have proved of inestimable value; the men who were "hard" then are respected now. Those gardeners who are strict, firm, kind, and just are those who have been the means of training men who have proved among the best in their calling, and worthy representatives of the vocation in which they are engaged. Young gardeners, too, should avail themselves of all possible means of self-improvement. Not long ago the manager of one of the best gardens in England had not one young man out of the seven or eight "in the botly" who could draw a plan of the very simple flower garden that was wanted for a particular purpose. He felt a little humiliated when he had to make that confession, and most certainly he ought not to have had to discharge such a disagreeable duty.

**Names of Fruits** (J. D., Sussex).—1, Wheeler's Russet; 2, Edmund Jupp; 3, Not known.

**Names of Plants** (W. A.).—If you will send numbered specimens of the Ferns we shall be able to make a reply intelligible to you, but those we have received are not marked in any way. (Ebor).—1, *Asclepias curassavica*; 2, The small leaf, which was quite shrivelled, was unrecognisable. Sprays have been received from other correspondents that are quite insufficient for identification, some of them owing to having been sent in letters and crushed during transit through the post.

#### COVENT GARDEN MARKET.—MARCH 30.

THE last few sunny days have brought a good supply of Strawberries to our Market, and with short demand prices have given way considerably. Trade keeps quiet, good samples of late Grapes only being in request.

#### POULTRY AND PIGEON CHRONICLE.

#### THE UTILISATION OF WASTE LAND.

(Continued from page 243.)

WE now follow up our proposals for utilising waste land by referring to what may be done by converting it into woodlands and plantations for the production of timber and underwood. The land requiring to be turned to account by planting trees will be various, for we have to consider not only certain soils appertaining to mountainous and moorland districts, but also those previously used as arable land, but which has been reduced to a comparatively useless state. We will first consider mountainous land intermixed with moors and peat moss. This will require draining as far as the peat bogs are concerned; and if the land is covered with Heather, Ling, and Gorse it may all be advantageously pared and burned, because a large body of ashes will be secured, which will furnish all the manure required for the growth of trees if the land is properly cultivated by steam power to the depth of 18 inches. These remarks do not apply to land comparatively inaccessible in high altitudes, because not only the difficulty of using steam power will occur, but also the effect of climate will often render it inadvisable to plant in such exposed situations. Again, in the peat moor portions of such land after draining a question will arise as to whether the peat can be dug and sold, or turned to advantage by planting in an improved state by the mixture of soils, such as sand, gravel, or clay.

We will now give an illustration of what we have known to be done upon land of little worth in a hill district with a favourable climate for timber, such as is often found in various parts of the kingdom where the rainfall is frequently beyond the average. In the case to which we shall allude the land had been purchased at £15 per statute acre, and turned to profit by planting with Larch Firs and Ash, at 24 inches apart. The cost of trenching or cultivating by steam power was estimated to have cost on the average £12 per acre. The planting as estimated would be done as follows for 1 acre:—Fir plants, 8800; Ash plants, 1440; total being 10,240 plants, distributed thus:—First row all Larch, second row every alternate plant Ash, the cutting to commence at the end of the eighth year, and the whole to be cleared at the end of sixteen years. The cost of plants would be about £12 10s., planting at £5 10s., making a total, including hoeing at £1, the sum of £31, with interest charged on outlay at £4 per cent. for sixteen years = £20. In commencing cutting at the end of the eighth year the produce would be 1280 poles at 3d. each, which would realise £16. The ninth, tenth, eleventh, and twelfth years would yield, 3840 poles at 3d. each, the sum of £48; the thirteenth, fourteenth, fifteenth, and sixteenth years would produce, after allowing for

failures (eleven trees per rod, or 1760 trees per acre), for 1920 poles at 3*d.* each, the sum of £24. Thus the 7040 poles would realise £88 per acre, and the expenses being £51 per acre would leave a balance of £37, or a profit, as a yearly rental, of 43*s.* per acre, the Ash stools remaining to produce underwood in the future; and it is of consequence to understand that these calculations of conversion refer to land only worth a few shillings per acre for any purpose, including sporting rights.

We must now refer to poor, flat-lying, strong, and tenacious clay soils, of which there is much in certain districts run to waste, or which has never been properly sown for permanent pasture. Such land is as unprofitable as any land we are acquainted with. It is, however, a fact, that some such land upon chalk subsoil has been planted with Larch Firs, and these where properly planted we notice are growing fast and looking remarkably well, whereas the adjoining lands of a similar soil in grass are comparatively worthless. We, however, are far from admitting that many such plantations are examples to be followed with advantage. Sufficient care and judgment has not always been exercised in the planting, either as to the cultivation and preparation of the land, the manner of planting, the distance at which the plants were set, or the treatment while they were young, all of which are so essential to the successful growth of plantations. As to the efficient working of strong soils, if there is a turf on the surface, however poor it may be, it should be pared with the paring plough and burned; nor is it necessary to be very particular as to the regularity of cutting the turf, because it will furnish more ashes if a larger amount of earth than usual is burned, which will prove useful when worked into strong land, and will enable the roots of trees to penetrate the soil better. The ashes should be charred, because, when stifle-burned, they form good manure, whereas when burned into red ashes they only act mechanically by opening the soil and rendering it more easily pierced by the roots of plants. After the land has been pared and burned and the ashes spread the fallowing may commence, for under any circumstances, even if it is not pared and burned on the surface, a fallow must be prepared as a prelude to any planting operations; in fact, if the land is not intended to be pared and burned in the spring it should be deeply fallow-ploughed in the autumn and lie during the winter. It will prove all the better if the subsoiling implement is made to follow the ordinary ploughing, whether it is done by steam or animal power, because any surplus water or rainfall will the more easily sink away into the subsoil. When the first cross-ploughing takes place subsoiling should be done simultaneously, so that the whole of the subsoil should be moved at the same time as the fallowing of the surface is going on. During the whole summer no harrowing, rolling, or scarifying should be done until just before planting time; but the ploughing should be done when the weeds make their appearance, and thus the land will be kept as rough as possible during the fallow.

Where land lies perfectly flat it should be ploughed into small ridges about 8 or 10 feet wide, but if it is at all undulating or hilly the ridges may be 24 or 30 feet wide, with the land furrows struck out deeply, and made out in the same way after planting. We shall, however, refer to this matter again after the planting has been set out and done. When shaping the ridges for planting, especially when it is to be in small ridges, the ridge-ploughing should be done as deeply as four good horses can lay the land into shape; the land furrows between the ridges will then be correspondingly deep, in which case the furrows should lay the subsoil entirely bare, so that the surface water may pass away freely. The planting should be done as early as the young trees will bear removal, which will be generally about the last week in September or the first week in October. This is a matter of no small importance, because strong soils should be planted whilst the land is dry enough to move freely, for if the spade-planting is done when the land is

heavy and clogging the trees will not flourish so well, as it will go far to neutralise the benefit of summer fallowing, upon which a serious expenditure may have been made.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This is the busiest of all times of the year except the harvest period, in consequence of the adverse weather extending all through February and into the first week in March; up to that time but little horse labour could be done with advantage on the tillage of the land by ploughing or otherwise. Fortunately we have experienced a favourable change in the weather, and the land has since worked well, being soft, moist, and fine on the surface, which is far better than when harsh winds have prevailed and suddenly dried the land. The small seeds, such as Clover and the grasses sown in Lent corn about this time, never vegetate with regularity when the land is rough and dry; these should be sown immediately after the ring roller, as the little grooves made by the rings of the roller form a good seed bed. Potato planting should be attended to now, for as soon as Barley sowing is concluded the late or second early Potatoes should be set, and after so much delay as there has been this year to save time is very important. In all those cases where the land was not dunged in the autumn or winter the application of guano instead of dung will much facilitate planting, as the application of the manure and the planting go on simultaneously. In the planting of the second early or late varieties of Potatoes we noticed last year in many cases where the haulm was very gross and luxuriant that it completely shut out the sunlight and drying winds so essential to the healthy growth of the crop, especially now this vegetable is so subject to disease. We therefore recommend in all farm cultivation where the land has been liberally manured that the lines of Potatoes should be 3 feet apart, in order that ploughing instead of scarifying may be done between them.

The sowing of Clover and grasses should if possible be done before finishing the work on the Lent corn, but we highly approve of sowing after Potatoes or roots fed off by sheep. It usually succeeds well in this rotation, particularly if the kinds of Clover are alternated, sowing one course with Broad Clover and Alsike, the next course with Dutch and Trefoil or Yellow Suckling. In some cases it is advisable to mix Giant Saintfoin with the Broad Clover if partial failure of plant is at all probable. We object strongly to sowing grasses with the Clovers, especially Italian Rye Grass, as it dominates and starves the Clover plant, particularly on the second cutting; it is, moreover, unfavourable for the succeeding Wheat crop. Of course if we are sowing grass for several years as old lea we must take three or four sorts of permanent grass, such as Timothy and Cocksfoot and Pacey's Perennial Rye Grass, in admixture with white Clover and Saintfoin, but without any Italian Rye Grass, as it is sure to make the old lea bare on the surface by its gross habit of growth as compared with other grasses. This Italian Rye Grass, however, has its place in the rotation, particularly on the stock farms upon the hills where no water meadows are available in the spring; it is then invaluable in a season like the present where a breeding flock is kept. Our plan is to sow it in the Wheat or Oats, and feed the grass in both the autumn and spring, and then plough and press for early Turnips, Thousand-headed Kale, or Rape.

*Hand Labour.*—Both men and women will now be fully employed in outdoor work, the men with Potato planting, preparing for Mangolds, Carrots, and early Swedish Turnips. The women should now go over the pastures and Clovers, taking up Docks and the earliest-rooted weeds with a small pick, but afterwards, in ordinary weeding of Thistles, &c., they must die if cut up with the spud or common weeding hook. The live stock on many farms are very short of the usual spring provision of roots, and where there is no large bulk of Mangolds for use great inroads must be made upon the hay Clovers by the feeding-off with sheep of large areas of the best and earliest grasses. There is one point to which we wish to call attention, it having been our practice for many years to sow a portion of stubble Turnips, and in consequence of a backward harvest, even as late as the first week in September, for if left without hoeing, and the bulbs very small, they will live through the severest winters; this year is an apt illustration. Therefore when they are allowed to run up to green in the spring they may be fed off by store or breeding flocks just before they come into flower, when it is valuable as a change from the water meadows or Italian Rye Grass for night folding. The land, however, should be clean, so that it may be drilled with Mangold seed afterwards. In this way we have grown fine crops of Mangolds, but not of Swedes or Turnips, for the bulbs of these we have found will decay, owing no doubt to the fact of the old roots and stems of the stubble Turnips having been ploughed under in a partially decayed state. Farm horses should still have Mangolds if possible as part of their daily allowance of food, and it should be continued until the earliest green fodder can be cut up for them. The horned ewes in those cases where their lambs have been sold fat should now be pushed forward with Mangolds and Bean meal, with a run upon the Italian Rye Grass. Where the lambs are kept for stock the meadows or Italian Grass will be sufficient, except in the case of lambs being held on for autumn grazing, they will then pay for decorticated cotton cake or cracked Beans. The early Down lambs for Easter markets should still have the best of food—cut

Swedes and Bean meal, with cake and cracked Peas always in the troughs. Where there is a provision of Thousand-headed Kale it is a valuable food for lambs to run forward to; still we prefer that fattening lambs should have no young sprouted greens of any sort if good sound roots can possibly be obtained. Teg sheep having been wintered with the view of being sold fat, now or after being shorn, should at this time receive Mangold and Bean meal if the Swedes are all consumed; for although there is an amount of danger from stoppage of urine whilst good wether sheep are eating Mangolds, yet the only alternative is grass food, such as water meadows or Italian Rye Grass, but in consuming either of these the change from root-feeding is so great that some losses must be expected from diarrhoea. The long-woolled flocks in the midland and northern counties are now in the midst of lambing, and in nearly all the districts where the pastures are early grass will be forthcoming when required; the other alternatives are Mangolds and Italian Rye Grass, but to provide these they must have been seeded by anticipation last year. Weaning calves will now require attention, and excellent calf food is sold by Messrs. Simpson, Bowick & Co., Thorley, and others.

### VARIETIES.

GRASS FOR PERMANENT PASTURES.—Messrs. Carters' manual on laying down land to grass (published by Messrs. Sampson, Low, and Co.), contains much information of interest to landed proprietors and agriculturists. The whole routine of preparation for sowing, management of the land and crops, manuring, &c., is concisely detailed. An interesting chapter on the geological formation of soils is provided, and descriptive lists of the various grasses and other useful fodder plants submitted.

— FANCY PIGEONS, by J. C. Lyell (*Bazaar Office*).—We have here a useful addition to Pigeon literature. Mr. Lyell gives a very complete list of all the works upon the subject which have been published. He deals largely with the Toy varieties, and fully describes some of the less known foreign sorts. The illustrations are numerous and well executed.

— AMERICAN CHEESE.—We cite the following from a daily paper:—We have long ceased to know what butter is made of, and now, it seems, equal uncertainty is to prevail with regard to cheese. People who eat American cheeses should be careful where they buy them, for twenty-one factories are at work in St. Lawrence, County Albany, U.S.A., making cheese out of lard. The gentleman's name who has invented this new delicacy is Crapser, and he is an Assemblyman of the Albany Committee of Public Health. Mr. Crapser makes no secret of his process of manufacture. The new cheese is made from sweet milk, from which cream has been removed at 40° Fahr., after standing twelve hours. No chemicals are used in this process, except some colouring matter. Mr. Crapser regrets that he has to work on the sly, but "the honest farmer would not take any advantage;" he gets along with them by paying more for their milk than it is worth. Seven of his factories are now making the lard cheese, which goes to Chicago, Boston, New York, and Baltimore; and 2500 boxes, each weighing 60 lbs., were made last year.

— THE CROPS IN ITALY IN 1880.—The following official statistics of grain and Potato crops in the year 1880 have just been published, and are as follows:—Rye and Barley, cultivated area, 1,193,577 acres; total production, 19,356,735 bushels—average per acre, 16.21. Oats, cultivated area, 949,832 acres; total production, 19,039,527 bushels—average per acre, 20.03. Wheat, cultivated area, 11,721,345 acres; total production, 148,645,753 bushels—average per acre, 12.28. Maize, cultivated area, 4,301,125 acres; total production, 89,448,293 bushels—average per acre, 20.80. Rice cultivated area, 380,727 acres; total production, 27,274,288 bushels—average per acre, 47.82. Potatoes, cultivated area, 171,255 acres; total production, 7,043,622 cwts.—average per acre, 41.12 cwts.

— BRITISH AGRICULTURE IN 1880.—Mr. Henry F. Moore has issued a manual on this subject, being a first contribution to an annual history of agriculture. It is principally a reprint of articles that had been contributed by the author to some influential newspapers, and contains instructive tabular records of the agriculture of the year. The following extract will show the character of the work:—"On an average of fourteen years the value of the Wheat crop to the farmer when the seed has been deducted is £7 4s. 11d. per acre; for the first five years, 1866 to 1870, it was £8 7s. 10d.; for the last nine

years, £6 12s. 2d.; and for the last five years—namely, 1875 to 1879, only £5 18s. 3d. per acre. The diminution between the first five and the last five years has been £2 19s. 7d. per acre, or a loss of nearly 37 per cent. Should present prices rule during the current harvest year an average of 40s. per quarter will bring the general average value of the Wheat crop of 1880 to not more than about £5 10s. per acre to the farmer. Fall in price as well as decrease in yield has conduced to reduction of the area latterly cultivated. The imperial corn average, or price in the selected markets employed for fixing the tithe rent-charge, averaged 53s. for fourteen harvests. It was 55s. 7d. for the first five harvests—namely, 1866 to 1870; it was 51s. 6½d. for the last nine harvests—namely, 1871 to 1879; and it sank to 48s. 9½d. for the last five years ending with 1879. Should the present Wheat crop have to be sold, as appears most likely, at no more than about 40s. per quarter, the average price for the last three years will be 42s. 10d., or 10s. a quarter below the average of the last fourteen years. According to no calculation of agricultural experts has it ever been shown how this cereal can be grown with profit in ordinary farm practice to realise only £5 10s. up to £6 per acre for the grain, unless rents and labour cost and public charges are materially modified. Yet, hitherto no one has demonstrated how the crop can be altogether banished from future rotations, or what necessary straw crop may be substituted for Wheat with a clear prospect of being remunerative in a majority of seasons."

### CHICKENS AND COOPS.

THE subject is a trite one; every novice in poultry-keeping delights to give his or her particular instructions for the management of chickens, and every poultry book has an elaborate chapter on the same subject. Indeed, it has often struck us that carefully to follow the rules of some of them would make poultry-keeping a somewhat irksome toil rather than a pleasurable recreation. Every year there are among our readers—at least, we hope so—novices who may be glad of a few simple and practical hints derived from the experience of an old hand. We will try to avoid all elaboration of detail, and to make them as plain as possible.

When the earlier chickens of a brood have been hatched from twenty-four to thirty hours they with the hen should be removed to a coop. It is not worth while keeping them waiting for any still unhatched after so long a time. If, however, there are eggs which show any signs of life in them, and there happens to be another hen on the point of hatching, they may be removed to her. If the mother appears ravenous she should first be placed by herself in the coop with plenty of food and water, and the chickens should be kept in the nest or a warm basket till she is satisfied. They should then be put down before her, and some light food, such as bread crumbs and yolk of hard-boiled egg, dropped before them; the hen, if a good one, will break it up temptingly before their eyes; they will eat what they want and creep under her breast. It is rare to find a hen wild and troublesome at such a crisis; if one should be so, leave her as much as possible to herself. She may step on a chicken or two, but if a fussy attendant rushes in horror at her she will probably trample upon all. Young chickens are much tougher than the inexperienced think, and when released from a wide foot often jump up as if nothing had happened. If, however, a hen is really a crusher of chickens she must be marked, and never again employed as a foster-mother.

The two all-important points now to secure the success of a brood are their housing and their food. We will here confine ourselves to the former, and reserve the latter for another article. Coops must be well made, watertight, with a good protection in front to keep out driving rains, and still well ventilated. It is pitiable to see the acts of cruelty which are often unconsciously perpetrated by the ignorant on wretched hens and chickens, which are exposed to every gust of a March wind in wicker coops. We have often expostulated with people who used such coops, and we have been told that many a brood is reared successfully at roadside cottages in such a way. This may possibly be true, but then the cottager runs out twenty times a day to look to them, turns them to catch every ray of the sun, protects them with an old sack from the wind, and at night probably takes them into the

cottage or to a snug corner in a thatched shed. Coops should be made of good inch boards, and those who cannot make and cannot afford to buy good coops have no business to rear chickens, unless they can give them the constant attention that the cottager henwife does. Coops for ordinary sized fowls should be at least 2 feet 6 inches wide, 2 feet deep from front to back, and 2 feet high in front, the roof sloping back to about 10 inches from the ground. Of course they must have detached fronts to shut up at night, but these must not entirely close them up. We always leave 3 inches at least at the top of their fronts open for ventilation, and this is protected by a wooden shelter in shape like the "bonnet" blind of a shop window when let down. We are convinced that far more chickens are killed by overheating and foul air in coops than by cold. Only those who have opened close coops in the morning can have an idea of the atmosphere which unfortunate chickens are constantly compelled to breathe.

Good coops being provided, it is of much importance where they are placed. No situation is so good as a shed facing south, and with a dusty dry floor. Sudden changes of wind will in such a place have little effect upon the chickens; they can run out in the sunshine, and retire from rain and snow. We always keep some of our own best poultry houses vacant for coops. The doors are always left open, save while the frost is on the grass or a snow storm is going on. Fresh soil and ashes are put down on the floor, and there we find the young birds thrive. Of course every one has not spare sheds; those who have not will find the best substitute for them in banks and hedges. In this country, where in spring our cold chiefly comes from biting wind, which is often accompanied by hot sun, only those who have tried it know the warmth to be found on the south side of a thick hedge or sloping bank. If this is so perceptible to human beings, much more must it be so to tiny chickens close to the ground, who are perfectly protected by the bank or hedge from all draught. It is often easy to throw up a bank of turves and so make a perfect place for a coop, or the protection of the roots of some old tree may be looked for. Such places are the natural resort for shelter of all the gallinaceous tribe.

Lastly, as to the flooring of coops. Where the soil is light and dry it is the best of all bottoms in a pulverised state. Where, however, it is sticky and heavy, sifted ashes will much improve it; if there is a little wood ash among the coal ash so much the better. Coops with wooden bottoms we never use, save for Bantams and delicate fancy Ducks. Neither of these races can bear the chill of the ground in cold wet weather, and must be lifted off it. Our own coops for them have wooden drawer floors, of which there are two to each coop; one is aired and dried whilst the other is in use. They are made by Messrs. Reynolds, and are called "The Shelter" coop. Of the more expensive coops we have never had any at all to equal them in ingenuity of make or practical utility. For such delicate birds it is an economy to have one or two really superior abodes. Of course the drawers when in use are covered with sand, light ashes, or soil to facilitate cleaning. Such has been our experience as to coops; we will give in another number that as to foods.—C.

### THE DORKING FOWL.

THE article on the above in a recent number of the Journal from the pen of so excellent a fancier and breeder as Mr. O. E. Cresswell is well worthy of the careful perusal and thoughtful consideration of those who take an interest in the Dorking fowl past and present. Like Mr. O. E. Cresswell I have been a poultry and Pigeon fancier from my boyhood. Forty-eight years ago I commenced the keeping of poultry with Bantams and white Aylesbury Ducks; from then till now I have continued a fancier more or less as regards keeping stock of my own. In the first edition of the "Poultry Book" some of the birds delineated were from my yard—notably the White Dorking cock, for I was a Dorking fancier in 1853 as now. He was a young bird when I painted from him, as may be seen by reference to his spurs, and his weight at that time was 10 lbs. all but 1 oz. The Silver-spangled Hamburgs were also from my birds. Although I seldom or ever exhibited, yet many of my stock took high honours even in America, especially my White Cochins, &c.; therefore I think Mr. O. E. Cresswell is scarcely within the mark when he writes somewhat slightly of those fanciers who from various causes do not exhibit.

The Dorking has during all the long years of my poultry fancy been one of the chief objects of my attention, and for many reasons, one being that several of my relatives being well-to-do farmers, Dorkings were the variety of fowl that I was most amongst, and from which as an artist I made many studies long before the poultry shows came into vogue. I also made studies from the

Dorkings at the Zoological Society's Gardens, and from almost the first at Birmingham I have attended professionally as well as a fancier until the last year or so.

In 1853 and thereabouts I saw the stocks of many of the best Dorking fanciers—Admiral (then Captain) Hornby's, the splendid birds of Mr. Fisher Hobbs, Captain Fairlie, and many others. I therefore feel that I am somewhat competent to give an opinion on the Dorking; the more so, as I not only saw the birds of the period I mention, but made notes and sketches of them. What I write is from personal observation, and not from books or periodicals, &c., like others in many instances are doing. Mr. O. E. Cresswell's paper I think, old and good fancier as he is, is worth therefore, as I have said before, grave consideration. I shall divide the subject into the same number of heads that he has, and proceed to give my unbiassed opinion.

*Form and Size.*—As regards form I do not consider the present Dorkings equal to those of some thirty years back. They are longer on the leg and not so wide. In the old Dorking the keel of the breast bone was sunk in, and the flesh rounded up from it like that of a fat Partridge; and to my mind such formation, only much enlarged, could not be surpassed for a table fowl. In the present Dorking the keel of the breast bone stands up, and the flesh slopes from it. Again, the birds are not nearly so narrow in the pelvis as the old, thereby carrying more offal and clearly showing crosses. Mr. O. E. Cresswell is somewhat wrong, though possibly right in the main, when he says that the Dorkings used to be judged from weight more than now. I think this must not be taken as representing fact at Birmingham, for I well remember going round the show some years ago with the best of all judges of the Dorking—Mr. John Baily, and I remarked to him that the first-prize bird was less than several others, when he said, "A Dorking was a fowl that was not judged from mere size and weight, but more for its quality;" and with this dictum I entirely concur. I am quite ready to admit that the modern Dorking is larger and more heavy, but much of the weight has been gained by the largeness of bone. There is much more offal in the modern Dorking. The constant aim of the old Dorking breeder was to get as much flesh as possible with as little bone. Again, how large ought a table fowl to be? The present fancy seems to be a rage for size, and everyone knows who knows anything of anatomy that the larger the frame the larger and coarser the tissues that form the muscles must necessarily become, for they do not increase in number according to the size of the bird; therefore, in large size we lose quality, and for no purpose. I had a fowl cooked a short time since that weighed 5½ lbs. when ready for the spit. This is small to what the modern Dorking fancier tries for, and yet I venture to say that no one, more especially a lady, would accept the liver wing if properly cut off on account of its size. It would be a good dinner for a man! Two fowls of 4 lbs. each when ready for the cook would be far preferable, and would I am sure be much more relished; and yet we are told there is an advance in the Dorking as a table fowl because it is 3 lbs. heavier than it used to be. Decidedly, in the opinion of very many it is not so good, and what goes partially to prove this is that there are several already trying to produce a good table fowl with less bone, finer meat, and less in size. This is a well-known fact, and one of our best judges—Mr. Tegetmeier—is among the number. Let the Dorking fanciers look to it. Some years ago that excellent judge of the Dorking, Mr. John Baily, told me that "the Dorking as a table fowl left nothing to be desired." It is long since I have seen Mr. Baily to converse with him on the subject, but I much doubt if he would say the same of the exhibition Dorking of the present time.

*Colour.*—I am by no means alone in much disliking the colour now called "fashionable." It makes a dark dingy-looking bird in comparison to the old bright browns and greys with the black tips to their feathers. Hereabouts we have thoroughly made up our minds not to have more of the sooty-looking birds. We will neither buy them nor their eggs for sitting. The colour was got by crossing and bred back to the cross, and is not the true Dorking colour; and we are determined not to have it forced upon us by a few breeders and judges backed up by some of the press. Some few years ago some breeders of the Spangled Hamburg fowls got some foolish judges to back them up with the idea that all the cock birds should have hens' tails, and for awhile—with the help of the press—they had their way, and made a good profit by it, until "common sense" would stand it no longer, and broke down the combination. It must now be so with the nearly black mixture so-called Dorking.

*Colour of the Feet.*—In all my long experience I never knew of dark legs in a Dorking till of late. We are told by the Dorking breeders themselves "it is a great blemish," and yet they will

increase alarmingly. People who buy eggs from prize yards have often nothing but dark-legged chickens; but we are quietly told they eat as well! Possibly, but as dead fowls we cannot sell them. The higgler will not take them of us as long as he can get a white-legged one anywhere; first-class poulterers will not have them at all, and yet we are told the Dorking is improved! It is no such thing. In the "Standard of Excellence" laid down by the Poultry Club the one particular defect as a disqualification, apart from deformities, was dark legs; but the modern Dorking is such a mongrel the dark feet cannot be got rid of. So no one who breeds for the markets will have anything to do with them. All eggs laid here are noted. Since I had the modern improved Dorking the number of eggs per fowl has much decreased.

**Colour of Ears.**—As long as I can remember the Dorking fowl it has had light-coloured ears, and to my mind the red ear is a clear evidence of cross, and I shall buy none with such. When I see light-coloured ears, rich bright-coloured fowls of good size and quality I feel myself safe in buying, but no more very dark birds for me, and, I may add, for others too; for hereabouts they are being disposed of—if I may use the expression—wholesale.—HARRISON WEIR.

I HAVE read with great interest the excellent and most impartial article by Mr. Cresswell on the relative merits of Dorkings of the past and present, and quite agree with him that the Dorking of the present day is both hardier and sounder in feet. Possibly the greater attention which is now paid to poultry may to some extent account for their being hardier; but my reason for believing they are sounder in feet than formerly is, that some fifteen years ago Dorkings of the highest quality were kept on the same farm where mine now are, and I well recollect how from time to time some of the best birds had to be killed owing to their feet being quite gone, while during the last five years I have only had to destroy one bird for this cause. Surely, then, if the modern Dorking is sounder in feet than formerly, it is a great point gained.

Mr. Cresswell, I am glad to observe, does not consider a pale ear a bad fault, as some, especially Scotch fanciers, do. There is no doubt red ears give a nice set-off or finish to a Dorking, but I would be sorry to see an otherwise good bird condemned for merely having a pale ear or a moderate amount of white in the tail. Dark spots on the leg Mr. Cresswell considers a great blemish, which should exclude both from the prize list and the breeding pen. May I ask, Does he consider spots on the leg worse than dark feet? I have seen a perfectly white-footed pullet show a dark spot or two on the leg. In my opinion nothing is more hereditary in stock, or more objectionable in the show pen, than a double nail or any malformation of the toes, such as a sixth toe.

So far from finding fault with the gentlemen who have judged the Dorkings at our leading shows during the two past seasons, I think they deserve our best thanks for having set their faces so resolutely against the leggy breastless specimens that used to win. There is just one point to which I should like to see a little more attention paid than sometimes happens, and that is to a neatly shaped fifth toe nicely turned upwards.

Much as I admire a hen or pullet of the so-called fashionable dark colour, showing the white shaft or watermark all down the back, I look upon colour as only a secondary matter, and during the last three years I have gained several prizes in good company with light-coloured birds of both sexes. One cockerel in particular, which won under two of our best judges both in the north and south of England, was little darker than a Silver-Grey, and mottled on the breast. Breeders of the old-fashioned Dorking need not, I think, fear to exhibit their light-coloured favourites under any of our recognised Dorking judges; provided they are good in size and shape with proper feet they are not likely to be passed unnoticed. If my memory does not deceive me, two of the prize pullets at the last Crystal Palace Show were decidedly light in colour, as was one of the winning cockerels at Birmingham.—M. F. SMYTH.

#### POULTRY CLUB.

A MEETING of the Committee was held at Charing Cross Hotel on Monday, 28th March. There were present Messrs. H. R. Dugmore (in the chair), T. W. Anns, R. A. Boissier, A. Comyns, S. Lucas, and L. C. C. R. Norris. The Secretary reported that he had issued a circular to the members requesting nominations to the vacancy on the Committee; that the only candidate duly nominated was the Rev. E. H. Morgan; that his nominators were Messrs. R. W. Brett, S. Lucas, and L. C. C. R. Norris; and that he was willing to serve upon the Committee. The Rev. E. H. Morgan was accordingly declared

duly elected. The following new members were elected—Mrs. Wilson, Watergate, Grantham, Lincolnshire; G. H. Maddison, the Rectory, Richards Castle, near Ludlow; and R. R. Godfrey, Watergate, Grantham.

A complaint from Mr. T. W. Anns that the three-guinea silver cup awarded to him at the late Eastbourne Show for the best pen of poultry in the Show had not been sent to him, was considered. Several applications had been made both by Mr. Anns and the Secretary of the Club to the Secretary and Treasurer of the Eastbourne Show without obtaining a settlement of the claim. It was resolved that in the event of the cup or its value not being received by Mr. Anns before the 14th of April, the Club should guarantee Mr. Anns the expenses of a County Court summons to recover the cup or its value from the Eastbourne Committee. It was also resolved that a copy of the above resolution should be sent by the Secretary of the Club to the Secretary and Treasurer of the Eastbourne Show.

A complaint from the Rev. E. H. Ricketts as to the management of the Bultth Show held in November last was considered. Mr. Ricketts stated that the owners of birds entered in the Selling classes were openly allowed to bid, and did actually bid for and buy-in birds in these classes, thus preventing their sale to *bond fide* purchasers, and that the Secretary had, in the case of four out of six pens knocked down to Mr. Ricketts at the auction at catalogue price, subsequently added 1s. to the price of each pen, on the ground that the catalogue price was the vendor's bid. A letter addressed by Mr. Cresswell to the Secretary of the Show had remained unanswered, and a subsequent letter sent on the 8th of March by Mr. Comyns, asking for an explanation, was also unacknowledged. The Committee resolved that the case was not one in which they thought it desirable now to undertake the responsibility of legal proceedings, but that they desired to record their strong condemnation of the practice of owners being permitted by poultry show committees to bid for and buy-in their own exhibits—a proceeding in itself illegal.

A draft circular to railway companies as to the rough handling of birds, &c. was approved, and directions for its issue given.

The preparation of a standard of excellence was discussed, and Messrs. Anns, Boissier, Comyns, Fraser, and Lucas were appointed as a sub-committee to consider the best method of collecting the necessary data for the preparation of the standard, and to report to the Committee thereon.—ALEX. COMYNS, *Hon. Sec. Poultry Club*, 47, Chancery Lane. March 29th, 1881.

#### OUR LETTER BOX.

**Leghorns and Minorcas (E. P.).**—We have had personal experience of the laying qualities both of Leghorns and Minorcas, and can recommend them. The Leghorns lay rather too small eggs to please some people. You will find classes for Leghorns at nearly all the leading shows, and classes for Minorcas at those in the south-west where they are most popular. We cannot recommend any particular exhibitor's stock.

**Oilcake for Cows (H. M.).**—Oilcake enriches the milk, but it does not increase the quantity. Brewers' grains, soft mashes, or similar food tends to increase the daily yield of milk, but it becomes very poor. We have for some years given about one cake per day to half a dozen or more of our cows that seemed to require it most, and we have not experienced any bad results from its use either in the flavour of the milk or otherwise. Perhaps there is nothing to which an unpleasant taste is imparted so easily as milk, and very possibly an over-supply of oilcake might have this effect; but we have found less cause to complain of this than anything else given to the cows to improve their yield of milk. Good linseed cake should be obtained.

### SPRING NOTES ON VINES.

**A**LL who possess Vines will now be considering what it is best to do with them to insure success in their culture. Experienced cultivators have fixed rules for growing Vines, and have no occasion to depart from them; but amateurs who may only lately have acquired a vineyard, and others whose previous practice may not have altogether pleased them, will no doubt readily accept any suggestions which are likely to help them.

Much valuable advice bearing on this matter has appeared in these pages of late years, but the great number of questions still answered weekly indicate that information on the subject is as eagerly sought as ever. Many of these no doubt come from new readers, and I daresay others who may have grown Vines for some years, often find difficulties arise on which they are glad of advice.

It is generally admitted that fruit trees have suffered much through the influences of the last three unfavourable seasons, and although many may think this can only be the case in the open air, I think it also applies to a certain extent under glass. The absence of sun is felt under glass as much as anywhere, and the ill effects of this deficiency of sun heat are very marked in the Vine. The chief value of the fruit, especially if it has to be kept long, is to have it thoroughly ripened, and the wood soon loses its fertility if only imperfectly matured for two or three seasons in succession. A long season of growth and early ripening of both fruit and wood in autumn are the best means of guarding against deterioration. August and September are generally our brightest months, and to have Vines growing instead of maturing at those periods is a great mistake. Early Vines that were started into growth in February or earlier will be safe so far as early ripening is concerned, but we must not forget the great number of vineries where the owners depend on their Vines being started into growth in a natural way as the days lengthen. In many such cases April will be nearly over before the Vines have commenced growing, and as five to six months are required to produce ripe Grapes, it will be seen that late starting is simply courting defeat.

To some it may appear extravagance to start Vines into growth in March or early April under the influence of fire heat, when by waiting a few weeks longer the expenditure would be greatly reduced. The latter practice is, however, not economical in the end, as it will probably lead to ill-ripened fruit and imperfectly matured wood in the autumn, the fire heat that is then wanted to finish the crop and afterwards prevent it from decaying far outweighing the expense

of a month's extra early firing in spring. Were the very latest Vines started into growth by the beginning of March, or as soon after that as possible, the Grapes would be thoroughly ripe by September, and the advantages of this system would soon be seen in the high colour and rich flavour of the fruit. The wood, too, would become ripener than it would do in the sunless months of October and November. The more delicate Grapes are, the better do they require to be ripened for late keeping; and it is only by starting Black Hamburgs at the time we have named, and having them ripe in September, that we can depend on them keeping until the new year or afterwards.

If all late Vines have not been started into growth, no time should now be lost in commencing. The inside border should be saturated with water, and when this is thoroughly done at the commencement of the season it will be long before the soil becomes very dry again. On the lower side of one of our manure heaps there is a large tank to catch all the liquid that runs from the dung. This tank often becomes filled during the winter, and to avoid losing any we generally empty the tank on to the Vine borders, and this has a good effect on the Vines when they commence growing. Liquid manure is better for Vines at the present time than pure water, as the size of the berries depends in a great measure upon the vigour of the young wood. In short, it is to the roots we must look for all our success in Grape culture. If these are in the finest possible condition atmospheric influences will be of secondary consideration, but imperfect root-action will never be compensated for by any attention to the stem growths. A balance between both, however, is what is most desired.

The growths must be trained and attended to from their first appearance. Those who leave long spurs in pruning will have many young shoots starting from each; only one, or not more than two, will be wanted of these. The weakest should be removed as soon as they are 1 inch long, leaving only two or three of the strongest for a time until it is seen which is most fruitful, and then remove the others. Crowding the rods and young growths is well known to be much against successful Vine culture, but the knowledge of this fact does not appear to deter many from adhering to the practice very closely, as in the majority of vineries we find, say, about a dozen of the side shoots on each rod bearing fruit, and double that number fruitless. To allow these all to bear would be overcropping, but to allow them all to remain on the Vine is as great an evil. What good they do it would be impossible to say, but the harm is easily seen. All Vines bear freely enough from the same spur for years in succession, so that fruitless wood need not be retained under the impression that from this will be secured the finest and only bunches the following season. If one-half of the fruitless shoots were removed an improvement would result in the wood and fruit remaining. To secure the best results from this practice the shoots should be removed before the bunches have flowered.

When Vines become old, although the roots may be in good order, the spurs run out far from the main stem, and sometimes both the bunches and berries are smaller than formerly. Young canes would alter this state of matters completely, and those having old Vines would do well to take up a few young canes from them annually. We do this regularly, and some of our oldest Vines have now clean healthy young canes, and that, too, without losing time or a crop, as the young rods reach the

top of the house in one season, and they are left the full length to fruit the following year. The lowest shoots on the old rods should be treated in this way, then the whole length of them is new. It is surprising what fine crops of fruit some young canes will produce. We have a cane now of Foster's Seedling which was taken up late last season for a little distance, and it is now showing a number of bunches as large and fine as the old rods. As these young canes do not throw out many side growths the first season, and are mostly confined to a single stem, their presence does not shade those on each side of them much.

The best Grape-growers admit a little air into their vineries night and day from now on to the end of the season. This keeps the atmosphere pure and is of much benefit to the Vines. In cold dull days ventilation should be very slight. Closing the ventilators early throughout the season will tend to secure quick maturity. Not a week should be allowed to pass without examining every growing Vine, removing all superfluous growths, and training the others in their proper places. Well-drained borders may have liberal waterings once a fortnight in proportion to the vigour of the growth and the state of the weather. A slight dusting of guano and potash thrown over the surface of the border before watering is beneficial. Mulehings of manure over heavy badly-drained borders do more harm than good, as such soil generally becomes sour and the roots perish.

Few are now in the habit of syringing their Vines so heavily as they did at one time; syringing, however, is good for Vines infested with any kind of insects, but except for this it has nothing to recommend it.—A KITCHEN GARDENER.

#### PRUNING MARÉCHAL NIEL ROSE—FLOWERS EXHAUSTIVE.

IN reply to "J. S., *Yorkshire*," (page 213), I may say that this Rose has not been easy to obtain from the trade upon its own roots for some years past. From some large Rose-growing firms it could only be obtained on the Manetti, and from others on the Briar or upon the Celine stock, and during the past few years the Briar has been used by the majority. "J. S." evidently entertains some doubts as to the condition of the Maréchal Niel Rose at Hooton Hall. I saw it in August last, when it was in exuberant health, as an excellent Rose-grower can testify who saw it at the same time. I still maintain, as before stated, that the cutting-back system is one of the wisest and most judicious that can be pursued. That the Maréchal will grow strongly at first is admitted by all, and make shoots at least 20 feet in length. These after flowering produce a number of side growths, while the main shoots are allowed to extend if wanted to cover a large space. Therefore the larger the space the greater the number of side growths, all of which produce flowers freely; and the more flowers produced the weaker the growth becomes, and the tendency increases to produce weak side growths, which flower freely, but after a number of years growth becomes checked. The plant then becomes constantly weaker, and eventually dies. When a large specimen shows this tendency under the strain of producing thousands of bloom, is it not wise to cut it hard back and add fresh vigour to the plant? or would "J. S." allow it to further exhaust itself and die, and then replace it with a young plant? From experience I am led to believe that one of the peculiarities of the Maréchal after growing on the extension system for a few years, is that it requires cutting hard back. This I believe will prolong the life of the plant considerably. I do not for a moment doubt that the Hooton Hall Rose if not cut back would continue to yield thousands of blooms for some time to come; but without it differs in the future from all others I have seen, it will commence in time to grow much weaker, and produce flowers inferior in colour and size, and doubtless in the end might die. This, then, leads me to ask, Why would it be a barbarous action to cut back the plant to the two shoots half way up the stem if a longer lease of its life can be obtained with certainty, and finer flowers than if left unpruned? "J. S." points to his much-pruned standards, but what would they have been if left unpruned? Perhaps dead, or at the least making weak wood, producing puny flowers, not to be compared with the flowers now produced when hard pruned.

If "J. S." will strike a number of Rose cuttings, or graft them and allow them from the first to carry the flowers they show, will the plants make as much progress as if the flowers were picked off? If not, I say a crop of flowers exhausts the plant.

Again, a number of plants are grown, say of Gloire de Dijon, to bloom in 10-inch pots, and a number of them flower well, the others not bearing nearly so many. The latter will make better growth the following year than the former and start earlier. Why is this?

Further, I have a number of young plants of the same variety from cuttings inserted last June, to grow under glass to be early ripened for early flowering in 1882. All were rested alike and started the same. Some were allowed to flower, from the others the flowers were removed as they appeared. The latter have started vigorously into growth, the others scarcely started at all. If the production of flowers in this case has not impeded growth, I must ask "J. S." what has? If no benefit is to be gained by removing the flowers, why are the nurserymen so anxious to remove all flowers from the quantities of Teas they annually raise until the plants are of a suitable size for sending out, also from the Hybrid Perpetuals that are lifted and potted in autumn to be sold the following year? If no better growth is to be obtained they would not spend the time and labour in removing the flowers.—WM. BARDNEY.

#### VEGETABLES FOR WINTER USE—WHICH ARE THE MOST SERVICEABLE?

I MUST preface the notes I send by stating that my remarks are not made to those who have a large staff of gardeners, but to many of your readers who, like myself, have a limited space and limited means.

First of all I think everybody will acknowledge that no crop for household use will give a larger return for the ground upon which it stands than Brussels Sprouts. I have tried the plants raised from seed sown in autumn, sown in early spring under a handlight, in March on a hotbed, and in the open later on, and believe from my experiments that sowing on a gentle warm (not hot) bed in March produced the most vigorous and productive plants.

Next to Brussels Sprouts in utility comes curled Borecole. I cannot say which is the best. That depends on the nature of the soil; but do not omit to grow the variegated Kale or Borecole. They are very hardy, very tender when cooked, and very beautiful when used as garnishing for dishes, being very useful for that purpose when other plants cannot be had. After Borecole and Kale come Savoy. In a general way they will stand a hard frost, and in fact they are more in season after a frost than before, but this winter has been too severe for even their hardy nature. Their weakest part appears to be just above the ground, for there the frost appears to have struck them.

I pass over Cabbages and Coleworts to Broccoli, these much-desired and required luxuries, for luxuries they are to most of us who have to raise them for our own use without artificial means—I mean without a hotbed, or frame, or handlight. Who can tell me of any variety which can be sown on the open soil, and will "come off" within a reasonable time for a succeeding crop? Let him tell your readers when to sow it, when to plant it out, and when will it be "due" to cut, for of all crops I have ever grown none have been so uncertain, so fickle in their early days, so liable to injury by frost and damp; and then if they live to "come to a head" some damp off, and many others sprout before the heads are fit for the kitchen, and there is no crop which occupies so large a space and for so long a period as Broccoli. Very few have stood the test of last winter about here, which is called a mild climate. All appear to have succumbed except one small batch of Wilcoves. Close by it a lot of Walcherens were killed, but the Wilcoves survived, and are looking well, owing, I think, to having been planted on poor land not over-manured.

Whatever may be at present the condition of your winter greens do not pull them up unless you are compelled to use the ground for other purposes, because from this time to June all your winter greens—Brussels Sprouts, Borecole, &c., will produce most delicate and delicious bloom shoots; cut them before the buds have developed into a bloom, persuade the cook to treat them as Asparagus, tie and boil them in a bundle as such, serve on toast with melted butter, and you may go on cutting the young shoots day by day quite as fast as you can use them, and they will be called for as fast as you can grow them.—G. O. S.

[We think our correspondent has confused Cauliflowers with Broccolis. The Walcheren cannot be properly compared with the hardy varieties of which the Wilcove is a type. The Walcheren is more of a Cauliflower than a Broccoli.—ED.]

ROSE REINE MARIE HENRIETTE.—This new Tea-scented Rose, raised by M. Levat and sent out in 1879, is a decided acquisition to a class of Roses that are general favourites. Two flowers of it

are on my desk as I write. They are full and globular, with abundant petals opening freely, bright rosy red on the upper side, and a peculiar greyish purple on the under side, which imparts a somewhat dull hue to the half-open blooms, charmingly relieved by the bright glowing tints of the reflexed edges. It has been described as a red Gloire de Dijon; and although it will not probably prove equal to our old favourite either in vigour of growth or size of flowers, it is likely to be much valued as a red-flowered climber—may I add as an exhibition Rose?—EDWARD LUCKHURST.

#### METEOROLOGY.

A HARD word to say, and not a very safe one to have to write, but it means merely in a general way a rain gauge and a maximum and minimum thermometer. Anyone with this stock in trade may begin to take an interest in the subject; and if he does, it is my experience he will soon take a great one.

It gives a charm to a rainy day it certainly never possessed before, to feel that every drop is telling upon the gauge and will come into account to-morrow at 9 A.M. Half an inch is delightful, an inch to have to measure very exciting, and I suppose, too, an event in an Englishman's life, and probably one he would not wish often repeated.

Also I think it makes cold more endurable to watch the fluid retreating before it towards the bulb; in fact one gentleman said, who had a limited thermometer, that the mercury went quite into the bulb, and he was most deeply thankful it was not able to go down any further. It is not altogether easy to take observations. The authorities very properly require most careful and extreme accuracy; and certainly the authority I know most about and quote oftenest is by no means easy to satisfy either in the quality of thermometer or rain gauge.

There are certain rules also to be observed as to position. But all this being overcome, I venture to predict great and increasing interest to be obtained in the taking of observations; and I think I may add thanks from our commander-in-chief Mr. Symons, who is always on the look-out for fresh stations, and who, I believe, now has several localities, important but unrepresented.—A. C.

#### ACHIMENES FOR LATE FLOWERING.

THAT Achimenes can be grown from cuttings most people know, but that it is the best way to grow these plants may be new to some. It is generally admitted that Dahlias propagated from cuttings of the young shoots without any portion of the old root produce the most satisfactory results, and if this is so with Dahlias why not with Achimenes? But as I have not proved it I will base my recommendation of cuttings on other grounds. Achimenes in summer are of comparatively little use here, the indoor requirements at that season not being so great as in the autumn, and there are generally plenty of plants in flower during summer without any special preparation; but in autumn, when shooting parties and early frosts come at the same time, there is apt to be a dearth of flowering plants unless ample provision has been made beforehand. It is then that the beautiful bright colours of the Achimenes are welcome, and there is nothing that I am aware of to prevent those who can grow these plants at all having them in as good condition during September and October as at any other time. That is one advantage which cuttings possess; but there is another and more important one to the busy gardener who has to grow a little of everything, and who not only has all his moments taken up, but all his indoor space filled till the frosts are gone, and he can venture to place some of his less tender productions out of doors—and it is this, that the roots need not be started into growth till the month of May, but the pots may be kept on a shelf high and dry, and then, instead of the ordinary tedious process of shaking the roots out and potting them, they may be started in their original pots by merely soaking them and keeping them in a moist situation. It will be seen that by this plan there is a saving of time at a very busy season, and of room when for every inch of space there are two or three candidates, each of which is half a foot in diameter.

I hope no one will take up your valuable space by telling us that this is not a new plan, because I am not interested in knowing whether it is new or old, old plans being just as good to me as new ones, and *vice versa*, provided they are good and economical. If I or anyone else invent any new thing which adds either to the pleasure or profit of a portion of our fellow creatures without hurting the rest we are doing good, and so I maintain we are while we are instructing the million in common everyday philosophy; but of course there are some of your readers who are more capable of instructing than of being instructed, and it is not for them we write excepting when we are obliged to remind

them that all are not clever alike, and that although one man may know all about a certain subject, or at least think he does, that is no proof that his next neighbour is not open to receive information. I am not writing this because I have any personal grievance, for most of your readers probably know by this time that I seldom waste your space on personal matters, most of my statements being well weighed before they are penned; and when I do not answer an adverse critic it is not because I am convinced of my error of judgment, or that I wish to treat anyone with contempt, but it is because I feel that I have made my statements in good faith. My opponent has probably done the same, and the public may be left to their own discretion as to whose lead they will follow, or they may pick up a hint all round and experiment for themselves, for it is quite possible that none of us are right in all details. But I feel very often that many of your more intelligent readers are prevented giving their experience simply because they are afraid someone will tell them that their plans and ideas are old-fashioned, and that they will be open to ridicule; but I can assure you that some of the pleasantest moments I have are in chatting with enthusiastic amateurs who have had no regular horticultural training, and that many a good original idea has been picked up from such men and women. I always find those who have a love of gardening talk freely with me. Why should they not be encouraged to take "our Journal" into their confidence? I hope, Mr. Editor, you will use your scissors freely when there is anything in MS. likely to deter a timid person from communicating his or her ideas, successes, or failures.

But I have forgotten where I left my Achimenes. They are just starting into growth in their store pots. They must merely be kept watered and shaded till they make growths, which can be put in as cuttings like Lobelias or Petunias, excepting that I place them in their flowering pots at once; but your readers will remember that I do not bargain for any cuttings missing, and those who cannot insure them all striking might perhaps do just as well by striking the cuttings altogether and potting them off afterwards before they become drawn. The plan here is to insert from five to a dozen in a 6 or 7-inch pot filled with light soil, and place them in a box covered with glass inside a hothouse or pit; they will soon strike root, when the glass of the box is gradually removed, and they are afterwards grown with Gesneras, Eucharises, and such plants as require warmth and shade, or they are sometimes grown in a frame from which early Potatoes have been taken, and where there is at first a little warmth from the fermenting material. The sorts grown are longiflora major, grandiflora, Bermundii, and a small scarlet which I think is called "Dazzle."—WM. TAYLOR, *Longleat*.

#### THE GRANGE, STRETFORD, MANCHESTER.

IN a recent visit to the gardens attached to the residence of John Heywood, Esq., at Manchester, I was greatly pleased with the healthy condition and floriferousness of the Orchids, which are grown in large numbers, under the care of Mr. Elphinstone, the able head gardener. In the warm Orchid house especially notable were some fine specimens of *Dendrobium nobile*, *D. Freemani*, *D. Devonianum*, and *D. densiflorum*, the three preceding flowering freely, and the last-named bearing a large number of buds. The useful *Oncidium sarcodes* was in excellent health, as were also *Cypripedium niveum*, the old and well-known *Phaius grandifolius*, and the beautiful *Ansellia africana*, which has been equal to or even surpassing some of the specimens of this distinct Orchid that have been recently noticed in the Journal. In the house devoted to Orchids requiring cool treatment were several large specimens of that useful species *Cœlogyne cristata*, indicating by their vigorous appearance the careful treatment they receive. *Disa grandiflora* is also grown very successfully, with *Odontoglossum gloriosum* and *Masdevallias ignea* and *amabilis*.

Roses in pots, too, form another important feature in this establishment and are similarly well grown, the foliage being strong and healthy and the buds showing remarkably freely, promising a fine display. Clematises in pots also receive considerable attention, and, as in all gardens where they are well treated, they amply repay the trouble expended upon them. In a very large vinery, where the Vines were advancing satisfactorily, was an uncommonly handsome specimen of *Rhododendron Gibsoni* covered with flower buds. All through the garden a very agreeable neatness was observable, and reflected credit upon the general management.—VISITOR.

DISBUDDING PEACH TREES.—I see it warmly commended in one of your contemporaries to commence disbudding Peaches at present. The practice of one of the most successful growers in

this locality is not to interfere with the trees until he can definitely ascertain what prospect he has of a good crop, and then to disbud and thin both foliage and fruit. This leaves the experienced grower a larger margin and wider direction in the distribution of what he is going finally to allow to remain, always excepting outward-growing shoots that cannot be utilised. Late thinning and disbudding is open to the objection that the tree is exhausted by so much as must finally be removed. Would some experienced grower state what practice he recommends, and why, for sash-covered wall Peaches?—W. J. M., *Clonmel*.

## THE EFFECTS OF ELECTRICITY ON VEGETATION.

(Continued from page 148.)

**MILDEW.**—It is the general belief that fungoid growths arise from minute spores or germs conveyed by and deposited from the atmosphere, wherein they are said to abound, and consequently to be ubiquitous—existing in everything and everywhere—ready at all times to spring into growth whenever and wherever the required condition needed for their development shall present itself. Whether this be the case or not there is no need for us now to inquire; but one point is certain—we have in the Fern case and the Cress seed experiment previously alluded to (p. 266, last vol.) an unquestionable explanation of what that condition is. The seed in contact with the positive electrode, being rendered electro-positive, was thereby made to absorb and combine with the oxygen constituting the negative “ion,” and thus forming an oxygenated carbon compound, for which there being no legitimate growth through the absence of a negative eliminating power, the cellular formation becomes differentiated into another character of non-eliminated growth—namely, the fungus mycelium. In the Fern case the confined air was also rendered negative instead of its normally positive condition, and the consequence was the whole atmosphere within became choked with fungoid growths accompanied by their peculiar Mushroom odour. Now the chief point to be remarked is this, that as soon as the atmosphere was restored to its normal electro-positive state the fungi speedily dried up and disappeared. From this fact we have indisputable proof that a negative atmosphere is an absolutely indispensable condition for the fructification of mildew and other fungi. It fully accords with all other known facts bearing on the subject, such as the exposure of mouldy articles to the air and the thorough ventilation of cellars, &c.; whilst sulphur and lime, absorbing the oxygen, arrest the action of mildew.

The part recognised as the Mushroom, being only an outcrop from the creeping mycelium, and requiring a special condition of the atmosphere for its development, and this being so different from the ordinary treatment required for flowering plants, it is not at all to be wondered at that, in the absence of any knowledge of what these conditions are, their cultivation should not be more uniformly successful. With regard to the atmosphere, the line of demarcation separating the electro-positive air from the negative surface of the earth is not at any particular fixed spot, but varies according to circumstances. It has been pointed out that plants in a dry state are almost non-conductors of electricity, but that they are made conductors by being filled with moisture. The same rule applies to both the air and the earth. If the surface of the soil be dry it carries the air-contact down to where it meets with a damper stratum. On the other hand, if the surface be saturated with moisture and the air be not in motion but stagnant, it extends the earth's negative electric state some way up into the air so as to have a zone of negative atmosphere immediately overlying the earth's surface. Now it is in this stratum of stagnant negative air that Mushrooms and other fungi luxuriate. We have an apt illustration of this fact in the readiness with which Mushrooms can be cultivated in damp cellars, and in the abundance annually produced in the caves of the quarries in the neighbourhood of Paris. To imitate these conditions is, then, the first point to be considered in their artificial production. To have a pit 1 or 2 feet at least below the level of the surface, and to have this enclosed so as to prevent too much disturbance of the atmosphere either by sun or wind; any ventilation to be high up, and preferably at the west or north-west side or corner. When growing abroad naturally in grass pastures, Mushrooms and other allied forms are mostly to be found in tufts of grass as high or higher than themselves, these preserving the damp negative atmosphere from being dispersed; but artificially this duty is performed by the layer of straw usually had recourse to; but it may be questioned whether some other more suitable material, either living or dead, could not be found. Then, again, it is not by any means improbable but that some foreign substance, such as decaying Oak roots, perhaps, or other material scattered on the surface of the bed might facilitate the production of the something like ganglionic

nuclei from which the fructification develops. These are both worth consideration and trial. In reference to liquid manuring, it is highly probable that those solutions which favour the production of mildew will be beneficial in keeping sufficient dampness in both soil and air. Almost all manures are remarkable for being diluquescent, or turning wet from exposure; and hence they owe a great part of their beneficial effects to the power of attracting moisture to the soil and air, and other part to their chemical changes exciting polar action. It should be kept in mind that a positive condition means dryness or a drying-up, whilst the negative state implies a uniform dampness or absence of drought. Thus, if Apples or Pears be kept in an attic or hayloft surrounded by a positive atmosphere, they will soon wither and shrivel up; whereas let them be placed on the floor of a shed or other position connected with the earth by conducting materials, and they will retain their plumpness to the last. The only possible drawback in this situation is their proneness to decay and mould, which now brings us to the next most important subject—namely, ventilation, which I will refer to in a future issue.—W. K. BRIDGMAN.

(To be continued.)

## CAMELLIAS AT WALTHAM CROSS.

DURING the past month Messrs. William Paul & Son have exhibited several large collections of Camellia blooms at Kensington, Regent's Park, and elsewhere, which have, as usual, attracted the attention and admiration of hundreds of visitors. Not only have the varieties represented been numerous and well selected, but the blooms have been generally of good size and excellent form, thus indicating the large extent of the collection and the care bestowed on their culture. The favourable opinion formed by inspecting the cut blooms exhibited is fully supported by a visit to the nursery where they are grown, for there plants of all ages and sizes from the latest “worked” batch to large and handsome specimens are found in the most satisfactory condition, vigorous growth, rich dark green foliage and abundant blooms producing a most pleasing display. One large span-roof house over 100 feet long is entirely devoted to specimens in pots, from which many thousands of blooms are cut in the course of the season; and yet about a week ago, so numerous were the flowers still open and expanding, that it seemed scarcely possible some of the plants could bear more. In several instances the branches were even bending under the weight of the massive blooms. More than two hundred varieties are grown, a number of course far exceeding those required in any private garden, but intending purchasers are thus afforded the opportunity of selecting varieties in accordance with their particular tastes, as all the best forms in commerce are represented. Several good lists of Camellias have been published at various times in this Journal, but for the advantage of the many new readers who have not seen those selections and have not the time to visit Mr. Paul's nursery I will briefly indicate the respective qualities of a few of the best varieties in flower on the day I was at Waltham Cross.

**WHITE.**—The old but exceedingly useful and beautiful *alba plena* is too well known to need description, and the same may be said of *jimbriata*; both are invaluable. *Ninfa Egeria*.—A handsome variety, with blooms of excellent shape, very full; petals of good substance, and pure white; foliage rich dark green, and habit of plant good. This deserves to be much more extensively grown than it is at present. *Compacta alba*.—Flower neat, symmetrical, of good substance, and pure white. *Montironi vera*.—Pure white; flowers large, full, and of excellent form. *Comtesse de Mastiana*.—A handsome symmetrical flower of good substance; white, occasionally tinted or flaked with rose.

**RED OR CRIMSON.**—*Reine des Fleurs*.—Flower of excellent form, full, and rich dark red in colour; a useful variety. *Bealii*.—Bright crimson, beautiful flower; very free, and one of the best in its class; late. *C. M. Hovey*.—Comparatively new; large flower, of good form and bright crimson, with somewhat of a scarlet tint. *Madame Lebois*.—Flower beautifully imbricate; fine light crimson, very free; an excellent variety. *Corallina*.—Colour deep coral red; flower moderately large. *Chandleri*.—Rich bright crimson; flower large, sometimes with few white blotches; very free in flowering. *Eximica*.—Flower of medium size and good shape; colour rich crimson.

**ROSE.**—*Marchioness of Exeter*.—Very handsome. Flower large, well formed; petals broad, bright rosy pink. *L'Avenir*.—A useful and pretty variety; flowers symmetrical, rosy pink. *Elegans*.—Flower full; petals neatly imbricated, bright rose. *Magnificent*.—Pink; flower large, petals broad and rounded, very profuse. *Livia Boromeo*.—Well-formed flower, rose, with a few white streaks. *Baron de Vrière*.—Peach colour; flower large, of good form, streaked with white.

**STRIPED.**—*Marie Theresa*.—Neat flower; petals broad and rounded, white striped with rosy crimson. *Rose de la Reine*.—Fine variety; petals rounded, of good substance, rose or crimson striped with white. *Beauty of Hornsey*.—Petals imbricated; flower symmetrical, rosy pink, with a faint white stripe. *Lavinia Maggi*.—White striped with crimson; flowers frequently very large and of excellent shape. *Countess of Derby*.—A beautiful variety, very free; flowers white, streaked or flaked with pink. *Belle d'Arglione*.—Petals thick; flower of good form, rose, with purple tinge and white stripes.

Other beautiful varieties are *Cup of Beauty*, bluish white; *Andrea Doria*, bright red; *Mrs. Abby Wilder*, white, lake stripe; *Prima Donna*, bluish white; *Countess of Derby*, white rose flake; and *Rafia*, dark crimson. There are many forms equally as good as some of those named, but the above would form a fairly representative collection.—S.

### USEFUL PLANTS.

*Urecolina aurea*.—The drooping clusters of yellow and green flowers produced by this plant are very pleasing in the winter months. After flowering the bulbs should be potted in a compost of loam and lime rubbish and placed in a light position, gradually diminishing the supply of water when decay is showing in the leaf, so as to ripen the bulbs for the next season.

*Torenia Fournierii*.—Among the few stove plants bearing blue flowers this is one of the best. It flowers so freely that the plants soon become exhausted, consequently propagating must be done three or four times in the year to maintain the stock of plants.

*Lachenalia tricolor*.—One of the best spring-flowering bulbs. They should be potted when about to start into growth, and be kept as near the glass as possible. A strong loam with a small portion of leaf soil I have found the most suitable compost. When well managed they will produce from six to ten spikes of red and yellow flowers in 5-inch pots.—A.

### CHAPTERS ON INSECTS FOR GARDENERS.—No. 20. NEW SERIES.

FROM the last family of the weevils, which includes the Scolytus and other species that infest wood, we proceed to our next group of beetles, very unlike the weevils in some respects, but resembling them in this circumstance, that the larvæ bore into and devour wood. General characteristics do not always suit every member of a group they are supposed to belong to, just as the natives of one district of Africa defined white men as "the wearers of tall hats;" yet all white men do not thus disfigure themselves. Thus, the next group of beetles is named the Longicorn division, from the length of the antennæ; but in a number of the species these adornments are not conspicuously long, though usually thread-like. Yet the Longicorns are easily recognised by persons who do not profess to be naturalists, owing to their large jaws, long legs, and long body broadening towards the extremity. These beetles from their habits are of special interest to those engaged in forestry, for throughout the earth we find their species are distributed, and the doings of British species give but a faint idea of their destructive powers in hot climates; still, several of them show themselves, or leave us the results of their operations, in our gardens and shrubberies as well as in the woodlands.

It is of necessity one of the peculiarities belonging to the history of most wood-boring larvæ, that neither the gardener nor the naturalist can discover how they work without cutting deeply into standing trees, which it is undesirable to do. One or two caterpillars that feed upon wood are said occasionally to migrate from tree to tree, but they are rarely caught in the act. The monstrous caterpillar of the Goat Moth does indeed diffuse fragrance (?) round, telling of its presence in trees; not so as a rule the larvæ of beetles, even where the perfect insect gives out an odour. When we have an opportunity of examining one of the Longicorn grubs, small or large, we notice that it is thin and flattened, with legs imperfectly developed; the movements of the creature depending entirely upon the muscles of the body and the head, the latter being covered with a horny substance that serves for a helmet. Having reached its full size the grub or larva must become a chrysalis, and were this embedded in the wood there it might die from inability to extricate itself: hence the larva usually finishes its career by working its way to a position where there is but a slight film between it and the open air. Some of these larvæ manifest a preference for decaying wood, and if only left alone time enough they certainly bring many trees to decay, though there are instances where the attacks seem to cause little harm. The death of some trees is hastened, subsequent to the operations of these and other wood-miners, by the exposure that ensues, as

cold and moisture penetrate into the heart of the tree. Empty burrows of beetle larvæ also become the resorts of various insects, molluscs, centipedes, and spiders.

*Prionus coronarius* is the largest British species of this division, and in size it approaches the conspicuous stag beetle, but it is less common. Though the eggs are usually deposited by the parents on or just within the bark, the larvæ bore deeply into the trees where they reside, and so they would be seriously hurtful in our woods if they were abundant; nor does it appear that they have a notable preference for any particular tree. The larval state lasts two or three years, and then a rather elaborate cell of chips of wood is constructed, in which the change to a chrysalis takes place. Towards the end of summer the beetles come out and repose during the day upon the trunks of trees. Owing to their dull brown hue they nearly resemble the bark on which they sit, and persons may be close to them without perceiving them.

A far better known species, and one more attractive in appearance, is the beetle called *Aromia moschata* (fig. 61), or the Musk beetle, from the scent it diffuses, which is not, however, at all like musk, and has been better compared to the perfume of the Sweet-briar. Once upon a time, and within my own recollection, the Musk beetle was to be occasionally taken upon the Willows that adorned some of those Surrey commons near London, that have either been built upon or otherwise spoilt by the growth of the metropolis. From the habit it has of making a shrill noise, not so unlike the squeak of a bat, exploring juveniles have given it the name of the Squeaker, warning other juveniles who are ignorant of insect peculiarities that it bites. It is pacific enough for all that, but

Fig. 61.—*Aromia moschata*.

Fig. 62.—Leg of ditto enlarged.

when a number of them are crawling upon a tree they will push each other about, and get their antennæ into a tangle difficult to unloosen. If an attempt is made to remove one of them from its hold, the insect grasps the bark firmly with its singularly spurred fore legs (fig. 62) until the hand is withdrawn, when it rapidly runs off. The Musk beetles are seldom seen in the act of flying. Few beetles of our own or of any land can rival the colouring of this species, the golden green of the wing-cases being chequered with beautiful tints of azure and purple. The burrows or tracks of the larvæ are of various sizes, and cross each other in all directions. The beetles seem to occur in companies, and they prefer those spots where rows of Willows occur near little streamlets. Though an infested tree will put forth leaves for years after it has been severely bored into, the end generally is that it falls or splits up in some heavy gale.

There are several lesser species allied to the preceding which have received names from the trees they attack. Thus the Aspen beetle (*Saperda populnea*), a brownish-black insect dotted with buff, is found upon Aspens, sometimes also upon Poplars; and the larva or grub bores into the shoots, producing enlargements here and there, and the shoots affected generally die. Many of these are fortunately killed by a parasitic fly, which pierces the branches with its egg-placer, and deposits its eggs upon or near the body of the unseen grub. *S. cylindrica* resorts to the Pear, the Plum, or the Hazel, in the branches or twigs of which its larvæ feed, pursuing the same mode as that of *S. populnea*. The only remedy appears to be that of removing and burning any shoots seen to be infected. Another of the Longicorns that proves troublesome in some places is the Wasp beetle (*Clytus arictis*), a long-legged fellow, black and yellow-banded, and which may be noticed during the summer dodging about amongst flowers, apparently with no definite object. Though it has received a designation from a sup-

posed resemblance to a much-disliked four-winged insect, a careful glance at it will at once reveal its nature. This insect does harm, not to the plants in the garden, but to the garden posts and palings, in which the larvæ feed by dozens, betraying themselves by the few grains of bitten wood that are perceivable in the exterior. Probably they seldom attack wood that is quite sound, though they hasten its ruin by their proceedings. One of them removed from its burrow appears as a whitish flattened grub and looks feeble, though the small head is furnished with muscular jaws which can pierce wooden fibre readily. The little beetle called *Gracilia pygmæa* is hardly a fourth of the size of the Wasp beetle, a slim insect, reddish brown, and also as larva a consumer of wood; but its taste varies, for the larvæ have been discovered boring their way into dry pieces of leather. One more species in this group must be mentioned, the strange insect called the Timberman (*Astinomus œdilis*), which is furnished with antennæ several times the length of the body, and hence readily broken. It is a Scotch species, seeking out Pines and Firs.—J. R. S. C.

### TEA ROSES.

MY remarks on this subject have led to many letters, and in your last number to the expression of somewhat contradictory opinions. My kind friend "A. C." welcomes the few remarks I made, while "A COMMITTEEMAN" censures me for alluding to anything that took place at a Committee meeting.

I am in hopes that if this latter considers the subject I was writing about he will not consider that I violated any confidence. We were discussing the schedule, and the subject of the number of Tea Roses required of nurserymen was much canvassed. I have always found that anything that has to do with Roses is a subject of much interest to your readers, and I have endeavoured by any legitimate means to place matter of interest before them; hence it happens that I have always given a short account of what has taken place at the meetings of the National Rose Society; but if this is not agreeable to any members of the Committee I will discontinue my practice, although I am not aware whether your correspondent is a member of this particular Committee.

With regard to my selection of Tea Roses, I wrote the article in question at my club, and I had not a catalogue to refer to, so had to trust my memory. I am much annoyed that I forgot to mention Marie Van Houtte, which is in my opinion one of the very finest Tea Roses. Madame Caroline Kuster ought certainly to be admitted into the list, but Comtesse de Nadaillac is such a poor grower that it is not worthy of a place in any but the largest collection. I fear the late severe winter and this bitter spring weather must have annihilated many tender Teas. We will hope, however, for the best; and as rosarians, however hampered by the weather, always seem to come to the front at some show or other, we may hope to see some grand Teas and Noisettes at the National Rose Society's Shows.—WYLD SAVAGE.

### THE CRYSTAL PALACE SCHOOL OF GARDENING.

PREPARATIONS have been made and rules and regulations provided for carrying out this project, which was one of the original educational purposes of the Crystal Palace. The school is to be in two divisions—1, Landscape Gardening: Chief Instructor, Mr. Edward Milner. 2, Practical Gardening and Floriculture: Chief Instructor, Mr. W. G. Head.

The project is an excellent one, and the curriculum is comprehensive, embracing, in the first division especially, every detail, scientific and practical, for the purpose of thorough and effective teaching. The Crystal Palace offers admirable facilities for the study and practice of landscape gardening in its various aspects, and the chief instructor has given abundant evidence of his skill as an accomplished landscape gardener. The course is of two years, and includes practical gardening and floriculture, and the fee is £110. Certificates are granted to competent students, and they will be aided to acquire professional work. This, however, is not a condition of studentship.

In the second division, Practical Gardening and Floriculture, the fees are less—£30 per annum; and wages are given—10s. per week the first year, 15s. the second, and £1 1s. the third year. The advantages are less too. We do not think that the present resources of the Crystal Palace are sufficient for the efficient training of young men for "professional gardeners or nurserymen;" and unless the Directors have made extensive additions since we inspected the working department of the establishment, or are prepared to make them, they will not, we think, succeed in their object. Lectures and theoretical instruction may be readily provided; but the "demonstrations on practical operations in horticulture" must, it appears to us, be unduly limited. The nursery

work of the Palace falls far short of that in private trade establishments. The propagation of a few genera of plants in great numbers and the preparing of plants for decorative purposes is very elementary practice in the vocation of either nurserymen or gardeners. It is not in this work that the latter fail, but in the regular supply of vegetables and fruits. This is the most important branch of gardening; and unless a young man acquires a thorough knowledge of the varieties and their characteristics in these sections, and has practical experience in forcing them when necessary, so as to ensure a supply of a given crop at a certain time—unless he learns by actual experience the time required to have each crop ready for use and the mode of producing it in its best condition, his knowledge on striking cuttings and potting plants will be of little avail. The Crystal Palace, so far as we are aware, offers no adequate facilities for this work, and there is no intimation in the prospectus that provision is to be made on a scale sufficiently large and varied to enable the teaching in this section to be of anything like equal value to that obtainable in hundreds of private gardens. When the Crystal Palace Company commenced growing plants for sale in a small way for visitors we thought that certain kinds of fruit, such as Grapes for instance, would have been equally acceptable to them and lucrative to the vendors. Possibly fruit culture is in anticipation, but we shall require to understand the particulars of it, and also those of the growing and forcing of vegetables, before we can regard the "school" of substantial value for those learning practical gardening. However competent an instructor may be, his teaching cannot be efficient without the means of demonstrating by actual practice the value of the lessons he must desire to impart; and these means, so far as we are acquainted with the establishment, the Crystal Palace Company have not yet provided.

Full particulars may be obtained on application to Mr. F. K. Shenton, Superintendent of the Crystal Palace School of Art, Science, and Literature.

### NOTES ON PANSIES.

PANSIES are now improving a little in cold frames after the winter and previous to being planted out. I sent a few plants away the other day, and could not help remarking what a difference the state of the cutting makes in the rooting capabilities of plants and their general healthiness. I prefer short healthy growths a couple of inches in length; but when our cuttings were taken the plants were dying in great numbers, and I could not exercise much choice with regard to their quality. The short cuttings were lifted with a network of roots and healthy growing tops, whilst the long strips were either not rooted at all or had a few short roots protruding at the end of the plant, the tops being more or less sickly. Last summer was a most unfortunate one in some gardens and nurseries. One large firm lost their entire stock of Show varieties. The Fancy varieties endure the sun and drought incomparably better, and are much superior for ordinary growers to the first-named section. The strongest we have were from Bath, but the majority of the sorts raised there do not open their lower petals here. Possibly the influence of climate may alone account for this failing. I ought also to state that this applies to Fancy varieties alone. The selfs succeed as well here as those raised in the north.

Doubtless the way to secure the finest blooms is to plant in a bed composed of fresh loam and manure; and it will be found that if the loam is somewhat heavy the blooms will be firmer in texture, the colours brighter and more clearly defined, than if grown in a lighter soil. I much prefer to have them in beds or borders in lines, with several flowers on each, than to have them in regular exhibition style. There is not much difference between the two systems if the soil has been well prepared and a mulching of decayed manure laid around the plants after being planted out. We set them out in lines a foot apart, and keep flowers picked off until the plants are well established, though these early blooms are as a rule very fine. In fine weather the plants make rapid progress, and it is necessary to allow a very restricted number of growths to remain if large blooms are desired. On the other hand, the larger plants will be much more showy where no prize blooms are wanted.

Pansies are easily raised from seed, which merely requires sowing on some light soil on a border. If in the summer time cover the bed with a mat until the seedlings appear, and when strong enough transplant them.

When the plants are somewhat exhausted in summer it is a good plan to pinch back the flowering growths and allow fresh ones to start, at the same time applying another mulch of manure to the surface of the soil. Cuttings may be taken at any season when growth is active. If kept cool and shaded they strike freely; in

fact, if selected from the base of the plants many of them will have roots when taken. Most of our cuttings are inserted at the beginning of September; they are dibbled into prepared beds in brick frames.—R. P. BROTHERSTON.

#### LYCASTE SKINNERI.

THIS very beautiful and useful Orchid is now well known and valued in most gardens where such plants are grown in moderate

numbers. The size, substance, and delicate colouring of the flowers render them very attractive, and a few good specimens are of considerable utility in any collection. An excellent example of what careful culture will effect with this Orchid is shown in the specimen represented in the engraving (fig. 63). This plant was grown by Mr. J. R. Stirling, gardener to H. H. Vivian, Esq., Park Wern, Swansea, and has had a dozen flowers open at one time, all from the single fine pseudo-bulb shown in the cut. Some of the flowers were  $7\frac{1}{2}$  inches in diameter, and

Fig. 63.—LYCASTE SKINNERI.

the pseudo-bulb itself was 5 inches long and  $6\frac{1}{2}$  inches in circumference. As such satisfactory results are not often obtained it may interest our readers to learn Mr. Stirling's mode of treatment, which he thus briefly describes.

"I find that *Lycaste Skinneri* succeeds well in a compost of good fibrous peat, chopped sphagnum, and charcoal or potsherds broken small, with a little silver sand added, never allowing the compost to become very dry during winter, and giving the plant very liberal supplies of water during the growing season, which is now commencing. We grow our plants in the coldest end of a succession Pine pit, a situation which seems to suit them admirably. I think too much cannot be said in favour of this lovely Orchid on account of its rich colouring, comparatively easy culture, and adaptability for decorative purposes. The plant in question has been flowering for the last month, and is

now placed in the house, where it will probably remain in bloom for a considerable time."

#### MARÉCHAL NIEL ROSE.

As you invite particulars respecting *Maréchal Niel Rose* it may interest you to know that I planted one in the greenhouse here between ten and eleven years ago, and under singularly unfavourable circumstances. The root is inside the house under a plant bench between a pipe and a brick wall, and so near to the former that I have put a slate packed with moss between to prevent the stem being scorched. No preparation was made, the soil being a clayey loam. The Rose is budded on a 2 feet 6 inches Briar stock. The longest growth is 30 feet. It is trained like a Vine up one rafter, and then spreads right and left at the top. It is in

vigorous health, and only has the weak old wood cut out. It has now about three hundred blooms on it in various stages. I cut the first about a fortnight ago, and I purpose sending you a sample Rose and foliage as soon as we have had a few more sunny days to colour the flowers well. I give liquid manure liberally to the Rose as soon as it commences growing.—THOMAS RENSHAW, *The Gardens, Ashbourne Hall.*

[The blooms are very beautiful, rich, and full; and the foliage is equally indicative of good health and culture.—ED.]

#### TRINITY COLLEGE BOTANIC GARDENS, DUBLIN.

SPRING flowers here are lovely. Hepaticas, Dog's-tooth Violets pink and white, *Iris reticulata*, *I. caucasica*, *I. Kolpakowskiana*, Violets of sorts, *Primula rosea*, *P. erosa*, *P. pulcherrima*, *P. abysinica* (verticillata), *P. acaulis* in variety, *P. Henryi*, and others. Narcissuses are strong; and some, as *N. minor*, *N. maximus*, and vars. of *N. Tazetta*, are very effective in the open air. Mr. Harpur Crewe's tiny *Bulbocodia* are charming in pots; and the rare double *N. Eystettensis*, figured by Parkinson 250 years ago, is fresh and lovely. One of the prettiest of all Primulas is *P. marginata*; and year-old seedlings of the tiny *P. scotica*, or Bird's-eye Primrose, are pushing up strong and fresh, as are also Dr. Regel's bulbs from Turkestan and the Caucasus. *Tulipa biflora* (white var.) is now pretty, so also are *T. triphylla* and *T. iliensis*. *Corydalis Ledebouriana* and the giant species of *Eremurus* are producing their great glaucous clusters of leaves. *Lilium giganteum* in a cold frame is a most effective fine-foliage plant; and the other Lilies—*L. auratum*, *L. Hansonii*, *L. Washingtonianum*, *L. speciosum*, *L. japonicum*, *L. longiflorum*, and *L. Kramerii*—are pushing up their great Asparagus-like shoots both in pots in cold frames and in open sunny borders. *L. testaceum* is stronger than last year, when it bore fifteen flowers on a stem 7 feet high.

There are two sides to Lily culture in the open air—sun *versus* shade. *L. auratum* and *longiflorum* and others on sunny borders are now growing, and I hope they may not be injured by those erratic frosts of April and even May. The same species planted at the same time in shady places are still below ground, and so may be better off eventually than their early neighbours.

*Ouvirandra fenestralis* is doing well in the Orchid house. It is now making leaves 10 inches long by 4 broad. It grows in a milk pan placed on two 4-inch hot-water pipes. The plant is potted in pure peat in a 4-inch pot, the water being thus kept clean and sweet around and below the plant by watering overhead with a fine-rosed waterpot. *Conferva* is kept away by dense shade, a mat being nailed permanently on the roof above the plant.—VISITOR.

IT is announced that the SOCIÉTÉ ROYALE DE FLORE DE BRUXELLES will hold the 103rd Horticultural Exhibition in that city on the 1st, 2nd, and 3rd of May of the present year. The schedule enumerates 118 classes in three divisions; about forty gold medals being offered ranging in value from 100 to 500 francs, and a large number of silver and gilt medals are also offered. Fourteen classes are devoted to new plants; fine-foliage plants such as Ferns, Dracenas, Palms, and Crotons are similarly well provided for; Orchids, miscellaneous flowering plants, and groups have also numerous classes devoted to them. One section is devoted to fruits, in which fourteen classes are named, for Apples, Pears, Pine Apples, Grapes, Strawberries, and general collections. As the period of the year is one at which the Belgian horticulturists can exhibit to the best advantage, a satisfactory Show may be confidently expected.

— A CORRESPONDENT thus describes the good old mode of FORCING KIDNEY BEANS IN BOXES—“These Beans are frequently grown in pots, being either sown in the pots and top-dressed as they advance, or are sown in small pots and shifted. At Longleat a simpler and a commendable practice is adopted. Boxes

about 9 inches wide and 12 inches deep and made of a portable length are employed, thereby saving much labour in watering. Labour is also economised by sowing the seed in the full depth of soil, no top-dressing being then required. Bean roots certainly do to a certain extent find their way up into rich top-dressing. At the same time the stems, as Mr. Taylor pointed out, emit no roots; and why not, then, give them the full depth of soil in the first instance? Top-dressing unless properly performed—that is to say, at the right time and with warmed soil, is apt to seriously check the growth of the Beans, and in other ways do more harm than good.”

— THE same writer observes—“The list of LATE-KEEPING GRAPES is small, and what few we have do not meet with general approval. Much of course depends on the culture given, especially with Gros Colman and Black Alicante. Both are more attractive in appearance than Lady Downe's, but oftentimes are far from equal to it in point of quality. Black Alicante as grown at Longleat is excellent, but neither this nor Lady Downe's can compare with Mrs. Pince for quality. Mr. Taylor is one of the few who has retained this variety, hoping that it may recover its constitution so much impaired by over-propagation, and it would seem he is perfectly correct in his anticipations. Its great fault is the extreme redness of the berries, and this has improved; so that if not actually black it will still be very acceptable at the table on account of its noble appearance, plumpness and solidity of berries, and very agreeable flavour.”

— THE second edition of the schedule of the MANCHESTER INTERNATIONAL EXHIBITION, to be held in August next, as already noted, contains, in addition to the classes there mentioned, one for the best collection of Apples, “three of a kind, in distinct kinds. The fruit to be grown north of a straight line drawn from Carnarvon through Chester and Lincoln to the German Ocean,” the prizes being £5 and £3, offered by Messrs. Paul and Son of the Old Nurseries, Cheshunt, the same firm also offering £2 for the best dish of autumn Strawberries. Messrs. Webb and Sons, Wordsley, Stourbridge, offer four prizes of the collective value of £6 16s. 6d. for six distinct kinds of vegetables.

— A CORRESPONDENT writing from Canterbury observes—“I have read with much pleasure the account of a lovely plant I have had for the last three or four years, the CHOROZEMA CORDATUM VAR. SPLENDENS, which is now blooming in my greenhouse. It is 8 feet high, and planted in the ground like a Vine; it covers 14 feet of glass, and almost reaches the top of the house. It commenced flowering at the beginning of February, and will continue for some weeks. It spreads out in many branches, the tips of each bearing flowers profusely like the specimen I send you. The temperature of the house does not exceed 50°.” The spray sent indicates that the plant is in vigorous health, the leaves being large and deep green, and the flowers also of good size and richly coloured.

— AT the recent sale of the first portion of Mr. DAY'S ORCHIDS the total amount realised was £1847 7s., which included the following sums for rare species and varieties, and unusually fine specimens:—*Aerides Fieldingii*, £11 11s.; *A. Lobbi*, fine specimen, £19 19s.; *A. Schroderi*, £31 10s.; *Angraecum Ellisii*, £11 6s.; *Calanthe Textori*, very rare, £10 10s.; *Cattleya Bluntii*, said to be the only two plants in the country, £17 17s. and £44 2s. each; *C. exoniensis*, very strong plant, £23 2s.; *C. Mendelii*, fine variety, £11 11s.; *C. labiata Warneri*, £7 10s.; *C. labiata*, £23 2s. and £13; *Cypripedium Stonei* var. *platytænium*, 140 guineas; *C. Spicerianum*, £26 5s.; *Cœlogyne cristata Lemoniana*, £34 13s.; *Laelia elegans euspatha*, £16 5s. 6d.; and *L. alba*, £23 2s.

— “W. J. M.” sends the following upon THE WEATHER IN MUNSTER:—“The weather for the past fortnight has been very

remarkable. While there was any moisture either in the atmosphere or in the soil near the surface, we had sharp frosts (several degrees) every night, with scorching hot sun during the day, and a persistent dry north-east wind. At present, with a view from our windows of several miles, I cannot perceive anything green. Had the dreaded simoom from the African deserts paid us a visit I cannot imagine an effect more parching. I have been watering my outdoor hardy plants for the past week to keep them alive until more genial weather comes. Early buds and tender flowers have been dried up from the combined causes named. At present there can be no frost, because there is no moisture to freeze."

— WE learn that at a recent meeting of the DARLINGTON GARDENERS' INSTITUTE Mr. J. Bousfield read an excellent treatise on the "Mixed Flower Border," in which he gave particulars of the plants to be employed, and the mode of arranging them to provide a succession of flowers from early spring until late autumn. In the course of his remarks he thus referred to *Tropæolum Hunteri*—"I saw this fine *Tropæolum* at Raby Castle. It was dwarf as a *Viola*, and a mass of scarlet flowers even surpassing *Vesuvius Pclargonium*. Mr. Westcott valued it highly, and said he would propagate some thousands of it. He had it from Mr. Hunter of Lambton Castle, but though called by his name it was not raised by him."

— THE following GARDENING APPOINTMENTS have recently been made—Mr. W. S. Campbell, late gardener to Wm. Garnett, Esq., Lucan House (Fair Lawn), Ripon, has been appointed gardener to R. S. Donkin, Esq., Camp Ville, North Shields; Mr. Charles Warden, late foreman at Sarsden House, Chipping Norton, succeeds Mr. Frisby as gardener to Col. Bathurst, Clarendon Park, Salisbury; Mr. D. Judd, late gardener at The Castle, Warwick, succeeds the late Mr. Gray as gardener to C. Seeley, Esq., M.P., Brooke, Isle of Wight; Mr. William Hazel, late foreman at Warnham Court, Horsham, has been appointed gardener to Lady Ormathwaite, Warfield Park, Bracknell; and Mr. J. Legge, late foreman at The Castle, Warwick, succeeds the late Mr. Broadbridge as gardener to Sir Charles Mordaunt, Walton House, Warwick.

— AT the recent annual meeting of the NEWCASTLE-ON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY Mr. Gillespie, the Secretary, read the report, which stated that to place the Society on a firmer basis it had been resolved to incorporate it under the Board of Trade, with powers to form a botanic garden, should there be an opportunity at any future date. The Treasurer's report was read, which showed a deficiency of £234 3s. 7d. On this account the Committee have decided not to hold an autumn show this year. The loss from that source last year was £300. Mr. J. G. Riddell, Swinburne Castle, was elected President, and the Mayor of Newcastle, Alderman Angus, Vice-President for the present year.

— "W. R. K." writes as follows on the EFFECT OF THE WINTER ON ROSES NEAR MANCHESTER—"The last two winters have been the more disastrous to outdoor Roses than any since 1860, and amongst others I have lost many of the older varieties that have weathered all seasons till the last, notably Charles Lefebvre, Etienne Levet, Madame Charles Wood, Victor Verdier, Madame Victor Verdier, Général Jacqueminot, John Hopper, Eugène Appert, François Michelin, Sénateur Vaisse, Beauty of Waltham, and Mrs. Rivers, also the Baronne de Rothschild, which till the last frost appeared to have weathered the winters. Out of forty-eight varieties planted last season I have lost nearly three-fourths; the season of 1879-80 not quite so many. Last season many were cut down to the snow line, and afterwards made noble plants. This they appear to have suffered a little below the surface; but as I plant my Roses rather deep I hope to see good strong

growth again, but expect very few flowers except on those planted this month, which so far look very well indeed."

#### MR. WILLIAM ROBINSON.

MR. WILLIAM ROBINSON is apparently galled at losing his action for libel against us, and shows his chagrin in the last issue of his paper in a manner which we have no intention of imitating: we therefore will not bandy personalities with him. With reference to his puny threat "to notice our doings" in the future, the public when they see these "notices of our doings" will judge henceforth by what spirit our critic is actuated, and whether it is to gratify a feeling of rancour or to advance the interests of "the profession." As the statements he has made are only the puling of a twice-defeated person we let them pass, with an expression of regret that horticultural journalism should have been made the vehicle of so much ill-feeling engendered of disappointment. The charge he has brought against Dr. Hogg is absolutely false, and is of a very serious nature. It accuses him, while holding an official appointment in the Royal Horticultural Society, of using influence which that appointment was supposed to give him to injure Mr. William Robinson. He says, "Dr. Hogg when Pomological Director of the Royal Horticultural Society would not allow the *Garden* to be taken at Chiswick for the young men's reading or for the office." We are in a position to state that this is untrue, that all orders are and have been carried out through Mr. Barron, and that the following letter to Dr. Hogg received from Mr. Barron is a complete refutation of this base calumny—

"Royal Horticultural Society, Chiswick Garden, W.,  
"April 4th, 1881.

"SIR,—I observe a statement in the *Garden* of Saturday last, that whilst you were Pomological Director of the Royal Horticultural Society you 'would not allow the *Garden* to be taken at Chiswick for the young men's reading room or for the office.' I think it is due to you for me to say that this statement is untrue. As a fact the *Garden* was not one of the gardening papers taken in at Chiswick at that time, but I was never forbidden by the Board or yourself to order it, and since you have been Secretary it has been taken in regularly. I shall write to Mr. Robinson to correct the statement.

"I am, Sir, your obedient servant,

"A. F. BARRON."

We are at a loss to conceive what good purpose can be served by the course Mr. William Robinson is pursuing. Horticultural journalism has for the present generation at least been conducted with every sense of propriety, good feeling, and good taste; but the course he has adopted, not only towards ourselves, but with one or two exceptions to every one of his contemporaries, is devoid of either of these. He assumes the part of a censor of men superior in every respect to himself, and he criticises his contemporaries in a style which can only be characterised as impertinent. We will not treat our antagonist as he attempted to treat us, believing as we do with a daily contemporary that "there is no more pitiable confession of weakness than for one journal to appeal for legal protection against another. How can a newspaper which has so little faith in its own ability to defend itself expect to be respected by the public generally as a powerful organ of opinion?" We now part with Mr. Robinson as Uncle Toby parted with an overgrown fly that buzzed about his nose one day at dinner. "Go, I'll not hurt thee, says my Uncle Toby, rising from his chair and going across the room with the fly in his hand—I'll not hurt a hair of thy head: Go, says he, lifting up the sash, and opening his hand as he spoke, to let it escape. Go, poor creature, get thee gone; why should I hurt thee? This world surely is wide enough to hold both thee and me."

#### ABOUT FLOWER SHOW SCHEDULES.

SOME time since an esteemed friend of the writer, who is well known as an excellent contributor to your pages, drew the attention of your readers to certain matters in connection with the framing of schedules of prizes at flower shows. Many of the smaller societies which hold shows in the months of August and September will now be constructing or reconstructing their prize lists; therefore if the subject of classifying the various fruits and vegetables that are usually shown in collections could be discussed in the pages of the *Cottage Gardener* much good might be done, much dissatisfaction at the judges' awards avoided, many reflections on flower-show committees would be stopped, and generally speaking everybody interested, from the visitor to the judge, would be more certain of the objects aimed at and better satisfied with the results.

Collections of fruit or vegetables are one great source of annoy-

ance and of dissatisfaction; they also leave more room than anything else for cavillers and for the exhibitor who "never gets his ain." At a local show last year, where the term "collection of vegetables of eight sorts" was used, much dissatisfaction was expressed because of the winning collection being of no better quality than some of the others in any other respect save that of containing a dish each of Tomatoes and Globe Artichokes, which the judges, very properly I think, considered a better class of vegetables than Carrots or Turnips. This year the Committee, to obviate the difficulty, have inserted a clause prohibiting Tomatoes and Artichokes; at the same time they show their appreciation of the Tomato by offering a prize for six, of the same value as the prize for two heads of Celery. If some authority could lay down any rules by which the relative values of fruits and vegetables could be easily understood, such blunders as the one just referred to would be easily avoided. Of course the value of different vegetables or fruits would depend greatly on the season or time of year at which they were exhibited. In the same prize list alluded to the prize for one pint of Gooseberries is equal to the prize offered for six dessert Pears, while double the amount is offered for one Melon as against six Peaches. The same absurdity

of arrangement and apportioning of prizes is seen through the whole of the schedules of the shows in this neighbourhood.

Fruits and vegetables are not alone in the extraordinary manner in which they are valued by flower-show committees. The remarks apply equally to cut flowers and plants. Here is one specimen: For six exotic Ferns (varieties) exactly the same money is offered as for six Zonal Geraniums. Cut Flowers.—Twelve French Marigolds and six Hollyhocks are upon equal terms. Such is the state of things with us; and if Mr. Witherspoon will once more give us some of his ideas gained by a lengthened experience in these matters some good may be obtained. Surely gardeners and exhibitors will not allow such absurdities to exist in prize lists for ever. Let us have some standard authority whereby we can measure the relative value of each subject in each month of the year. There ought not to be any more difficulty in this matter than there is in deciding what should be the "weight for age" in horseflesh.—PETER FERGUSON, *Mere Knolls, Monk Wearmouth.*

#### FICUS STIPULATA.

EVERY gardener is acquainted with *Ficus stipulata* under its

Fig. 64.—*FICUS STIPULATA* (FRUITING AND BARREN BRANCHES).

more common but less correct, name of *Ficus repens*. In many gardens it is largely used as a neat and effective shrub for covering moist and shady walls or rockwork, a purpose for which it is unusually well adapted; but not the least interesting feature connected with the plant is its dimorphous character as occasionally shown under cultivation. If I mistake not, this may be seen in both its large and small-leaved phases in one of the plant houses in the Chelsea Botanical Garden, but I am not aware that fruit is produced there; indeed the fruiting of this plant in cultivation is a very rare occurrence. A few weeks ago, however, Mr. Bewley of Blackrook, near Dublin, very kindly brought me fresh specimens of the fruiting branches, one of which is shown in the accompanying illustration, along with a twig showing its small-leaved and usual growth. Both branches and fruit are shown of the natural size, and so distinct are the fruit-bearing branches from the creeping slender-growing ones that we might be excused for doubting their specific identity, the large-leaved fruit-bearing branches being more like those of *Ficus barbata* in general appearance than those of the species to which it really and truly belongs. Wonderful as the dimorphous characters undoubtedly are in the plant we now figure, there are analogous if not precisely similar instances of it in other genera, the common

creeping and the sub-shrubby or erect-growing forms of the common Ivy for example. Among aquatic plants *Pontederia* (*Eichornia*) *azurea* and *Ranunculus aquatilis* both exhibit dimorphism in an unusual degree, nor must we omit to notice one or two species of *Pothos* and the allied *Maregravias*. Again, the first leaves of the *Sagittaria* are simply strap-shaped and floating, and quite unlike the erect arrow-head-like leaves produced by the same plant later in the season. Some *Acacias* and the Australian Gum Tree (*Eucalyptus*) also have dimorphous leaves; but of all the cases of dimorphism known to me, none is more striking or more interesting than that of *Ficus stipulata* as here engraved.—DUBLINENSIS.

#### GYMNOGRAMMA SCHIZOPHYLLA.

FERNS are now so largely represented in most gardens, and their gracefulness so generally admired, that the demand both for the old well-known species and for novelties is very extensive. In consequence immense numbers of Ferns are grown for sale, and there is a corresponding influx of rare or previously unknown forms which collectors in various parts of the world are constantly finding and despatching to this country. To such an extent indeed is the dis-

covery of new Ferns now carried, that a very high authority upon the subject has estimated that additions to the list of known species or varieties are being made at the rate of fifty or sixty per annum. Many of these are only received in a dried state, and of the others comparatively few are sufficiently distinct or elegant to merit much attention from horticulturists. One of these few is, however, the new member of a well-known genus represented in fig. 65, which was obtained by Messrs. Veitch & Sons of Chelsea from Jamaica a short time since, and as it is likely to become one of the most graceful basket Ferns, it well deserves the attention of all who are interested in such plants.

*Gymnogramma schizophylla* does not possess the beautiful dusting of gold or silver farina which renders the fronds of many of its relatives such popular favourites, but the extreme elegance of its habit and the graceful contour of the fronds amply compensate for the absence of the characteristic covering. The fronds are very finely divided, tripinnate or decompound, the ultimate divisions being small, linear, notched at the apex, and bright green. In a young state the fronds are tapering or lanceolate in outline like those in the centre of the plant represented, but as they

become older the opposite pinnae about the middle or towards the base extend considerably, thus imparting somewhat of a triangular appearance as seen in the lower fronds of the engraving. They scarcely exceed a foot in length upon the living specimens I have hitherto seen, but dried fronds have been received nearly twice that length, and proliferous towards the extremities as in some *Aspleniums* and other Ferns. The graceful arching habit of the fronds renders the plant especially adapted for culture in baskets, as the woodcut which was prepared from a specimen in the Chelsea nurseries admirably shows; and suspended from the roof of a warm fernery sufficiently low to enable the whole form of the plant to be seen, it can scarcely be rivalled when in good condition. The quick growth and healthy appearance of young plants suggests that this Fern would not be difficult of cultivation provided due attention be paid to ensuring efficient drainage either in pots or baskets, but if grown in the former the plants need elevating upon something owing to the fronds drooping over the sides. One great recommendation of the plant is that it can be readily raised from spores, which, like those of several of its allies, grow very quickly, and a stock of young plants can thus be

Fig. 65.—GYMNOGRAMMA SCHIZOPHYLLA.

soon obtained, for the spores seem to be produced freely after the specimens reach a moderate size.

The Royal Botanic Society awarded the introducers a certificate for the plant at the recent show. It should be grown in every collection of Ferns.—L. CASTLE.

#### ROSES ON THEIR OWN ROOTS—THE WINTER.

MANY thanks to Mr. W. Taylor for his contribution to the subject of Roses on their own roots. His practical experience would rather seem to bear out my views that it is quite worth while to try them, and I do not doubt that those who follow his directions will not regret the trial. Last year will not, I fancy, prove a very favourable season for the experiment, for although my cuttings in the frame are looking fairly well, those outside are, I fear, nearly all lost. Mr. W. Taylor mentions the ease with which the Teas strike, and there again we have what I have mentioned before in writing of the Hybrid Perpetuals—an almost thornless wood. Whether it be the case or not that thornless varieties strike more successfully, I still trust that many of my amateur brethren may try the experiment and report progress. "OXONIAN" thought my previous letter on the subject proved that it was a difficult and lengthened affair to have Roses well established on their own roots. If he were to see the Teas that Mr. W. Taylor can produce I fancy

he would be somewhat surprised. Had I any frames I feel certain that more than half would strike. I am going, however, a little further. Since I wrote in reply to "OXONIAN" I have paid a visit to the garden where the bulk of my plants are, and I was dismayed. It is situated low, and it is exposed to the full effect of the braeing north-easter. There was a blackened mass of sticks of varying shades, scarcely a solitary stem retaining any appreciable green. Protection for several inches had been given, and with a heavy heart I proceeded to remove a little of this, and was rejoiced to find the colour below different. That was six weeks ago. The last ten days—it is now the 17th—I have been pruning, and no one going to that garden would believe I had any Rose trees; they would see some beds with apparently a little litter on them, and here and there might recognise a Rose stump, for out of about six hundred dwarfs (excepting the forty or fifty on their own roots) not twenty could be pruned leaving 2 inches above ground, and many have been pruned an inch below the surface. Shall I have any Roses? Well, I live in hopes, but I am convinced that it is no use trusting to wood that is practically dead, though many will say, "Dead! Why, look how it is pushing out shoots." Well, May and June will prove the value of such shoots. Out of the forty or fifty on their own roots certainly half are less damaged by the severe cold than are the old plants, and I have been able in several of them to leave some inches above the surface. This

may be accidental, but the plants are all together, and no difference made in them, and the result is quite unexpected to me.

At the back of my house, in a far more sheltered spot surrounded by buildings, I have about three hundred dwarfs, and these I fondly flattered myself were not so much damaged. The buds were becoming full and the tops bursting into leaf, only one here and there appeared black; but they will not bear inspection, and nearly all must be cut to the ground before arriving at sound pith. Beautifully as many seem to be growing, cutting-off shows a stem green on the outside truly, but the heart as brown as possible. We had 28° of frost in Wiltshire before the snow came, and afterwards 32° was registered by a neighbour, whose thermometer had but recently been proved. I cannot but think that for such temperatures a well-established plant on its own roots has a better chance than any budded specimens.

"A. C." speaks of his standards. I have but a dozen. One, Annie Wood, I should say is hopelessly gone; another, John Hopper, and another, La France, now look like "A. C.'s" knobs on a stick, and I cannot help thinking they will do as much without the knob as with it! Another great favourite, an old-established plant, from which I generally cut from twenty to thirty blooms, Jules Margottin, has old wood as thick as my finger, the pith of which is intensely brown. I do not expect to see it bloom again; the others I have not cut. I was in a neighbour's garden to-day. She is a devoted worshipper of Roses, and she did not think hers were hurt, but the standards are all the same. I was also in a cottage garden where the poor woman takes a pride in her Roses, and where she had recently filled the gaps in her beds by new plants. I went to one and cut off one of the two shoots on it; the result was the same—pith quite brown. Here I believe that unwittingly dead plants have actually been sold; and if I state my own belief, it is that very few standard Roses in this neighbourhood are good for anything but firewood, and they are not valuable for that, as their thorns are in the way.

All this is the more grievous, for I verily believe that more persons joined the ranks of Rose enthusiasts last year than ever. I ordered several hundreds for various friends. Mr. W. Paul, writing to me not long since, said he had never known so many new persons "going in for Roses;" and what a damper this will prove if many standards and not a few dwarfs are lost. My few Teas I have not yet examined, but Souvenir d'un Ami, dwarf and resting against a greenhouse, and forgotten as to protection, is, thanks to the wall, better than any Rose I have yet cut. Triomphe de Rennes (a standard) against the wall is only a knob, and that I fear dead, whilst a dwarf alongside is cut to the ground.

One word to my old friend "WYLD SAVAGE." He used to be a grower of Teas. The Tea election proved there were not many worth much, but still I fancied that "WYLD SAVAGE" could have named twenty-four that would grace a stand. What has happened to his beloved Marie Van Houtte? Again, cannot Cloth of Gold be added to the list? One of your correspondents has named Jean Ducher and others that certainly at their best are fit for a stand. I agree with "A. C." in believing that Comtesse d'Oxford has suffered terribly.—Y. B. A. Z.

#### KITCHEN GARDEN.

ANY deficiency in the plantations of Rhubarb through the roots being lifted for forcing purposes should now be made good. Plants for this purpose are generally those that have been used for forcing, but they are not so good as plants taken at once from the ground. Divide the roots, reserving two or more crowns to each. Plant in rows 4 feet apart and 3 feet asunder, and for permanent plantations allow a foot more distance between the rows and plants. Healthy portions 4 to 6 inches in length of Seakale roots that have been reserved in sand as the crowns were lifted for forcing, have now formed a callus, and should be planted in well-prepared ground 2 feet apart in rows 1 foot asunder. Crowns that have been lifted for forcing and afterwards hardened off by placing them in sand in a cool shed should also be planted out, and they will be again available for forcing when the time comes round. Roots that were rejected as too small for forcing must now be planted, and if they have prominent crowns and are likely to start into flower-heads remove the point with a

knife. Where seed is intended to be sown sow it in drills about 18 inches apart, and thin the seedlings to about 12 inches. The protecting material may shortly be removed from around the crowns of Globe Artichokes, and should be replaced with a mulching of manure about 3 inches thick. To secure large heads of this esteemed vegetable it is essential that vigorous young plants be obtained, and for ordinary purposes a new plantation should be made every year about this time; these plants will afford a moderate quantity of heads this autumn and produce abundantly next season. Retain a portion of old root to each division, choosing pieces with two or three suckers, or if more reduce them to that number, planting rather deeply in rows 4 feet apart and 3 feet asunder. Water if necessary, and mulch to prevent evaporation. Planting out autumn-sown Cauliflowers, Cabbage, Lettuce, and Tripoli Onions has been impeded by the weather, but no time should be unnecessarily lost in proceeding with the work. Cauliflowers, Cabbage, Brussels Sprouts, and Lettuces that have been raised in heat, pricked off, well grown, and hardened, should be planted out when the weather is favourable. Peas sown in pots or turves may be planted in warm borders, placing the sticks thickly as a protection. The principal sowing of Broccoli should be made at once; Penzance, Cooling's Matchless, Leamington, Lauder's Goshen, and Model are good sorts for early spring succession and late use; and for late autumn and winter Snow's Winter and Veitch's Protecting Autumn. Sow Brussels Sprouts, Savoy, Borecoles, and Cabbages of the early varieties for autumn use, and Cauliflowers, Walcheren and Veitch's Autumn Giant, for a supply of heads from August or September onwards. The young plants from earlier sowings of Brassicas when large enough should either be thinned out or be pricked off in prepared beds to secure a sturdy habit. Sow Celery in rich soil on a sheltered border; plants from this sowing are for late use preferable to those raised in heat. Attend to the requirements of Peas in earthing up, staking, and guarding against the ravages of birds and slugs by dusting whilst damp with soot, dry wood ashes, or quicklime. Make successional sowings of Peas and Broad Beans according to the probable requirements. Sow also the principal crop of Carrots for winter use and Beet for early use, Egyptian coming in quickly, deferring the principal sowing until the early part of next month. Salsafy and Scorzonera may now be sown in deep rich soil in drills about 15 inches apart, covering an inch deep, and guarding against mice. Sow Basil, Sweet Marjoram, and Summer Savory on a warm border, and on a sheltered one Thyme, Sage, and other perennial herbs that may be raised from seed. Divide and replant herbs generally when necessary. Complete the planting of early Potatoes, proceeding with the second early.

*Forcing Department.*—Supply water if necessary to Potatoes before earthing them, but less will be required as the tubers attain to a size for use, as too much of it will deteriorate the flavour. Thin-out later crops of Carrots, and plentifully supply them with water, also Radishes and Lettuces. Prick off Celery from seed pans in rich soil over slight bottom heat, affording sufficient warmth to ensure steady progressive growth. Sow Tomatoes and Capsicums. Transfer Tomatoes into their fruiting pots, and remove all side growths, one stem being most suitable for plants in pots. Whenever the weather is favourable ventilate freely all frames or pits containing vegetables. Earth up advancing crops of French Beans in pots or in pits, supplying water copiously, and if necessary liquid manure. Sow as needed to maintain the succession unbroken.

#### PLANT HOUSES.

*Greenhouse.*—Cuttings of Salvias should now be inserted so as to have good plants by autumn, also Linum trigynum and Libonias. Bouvardias and Tree Carnations require to be struck early and to be potted and well grown to procure strong plants. Sow seeds of Primula sinensis for autumn flowering, employing good loam with about a third of leaf soil and a little sand; also sow Cinerarias for autumn flowering. Calceolarias should be potted as they require it, selecting the most vigorous and such as are not yet showing flowers, and when they are rooted in the fresh soil supply liquid manure. These plants like a humid atmosphere and to be kept in a cool position, fumigating upon the first appearance of aphides. Supply Pelargoniums now showing their flowers with weak liquid manure, and if the pots are

filled with roots the soil must not be allowed to become dry. Keep the shoots well trained and tied out. Plants intended for July flowering should have the points of the shoots pinched out to cause them to break back, and if in comparatively small pots shift into others a size larger. Keep a strict look-out for aphides, and fumigate promptly upon their first appearance. Repot Fuchsias, stopping the shoots until the plants are sufficiently furnished, which more particularly applies to those required large for conservatory decoration. Syringe every afternoon to keep down thrips and red spider. Chrysanthemum cuttings that were inserted late last year are now ready for potting off or shifting into larger pots. Employ good loam with about a sixth of decayed manure and a sprinkling of bone dust. Pinch out the points of the shoots of such as are required to break back, but those for specimen blooms should be stopped. Place the plants on ashes in a cold frame, and ventilate freely in favourable weather. Acacias will now be making a fine display, and must not lack water at the roots. When they cease blooming cut in any irregular growths, and if there be any white scale free the plants of it with an insecticide. Camellia plants that bloomed early will be growing, and should be placed where they can have slight shade, and a temperature of 55° at night and 10° to 15° advance by day. Afford plenty of moisture at the roots, supply weak liquid manure to plants in small pots. Those that bloomed at midseason will also be growing, and should be encouraged with moisture, shade, and a slight increase of temperature. Late varieties, such as C. Beali, red, and C. candidissima, white, must be shaded and kept as cool as possible.

Epacris that have flowered should be pruned, and if the plants are as large as required they may be cut back to within an inch or two of the old wood. These plants bear cutting-in annually to a greater extent than most other hardwooded plants, hence the size of the plants can be regulated according to the taste and requirements of the cultivator. If cut back freely the plants must be confined to comparatively small pots, or they will not thrive satisfactorily. A slight increase of temperature and the damping overhead from a syringe in the afternoon will be beneficial.

Heaths should now be examined, training their flowering shoots in the position they are required to be when in bloom; in doing which use as few sticks as possible—only sufficient to keep the plants in proper shape. Any plants required for blooming later should be placed in a house where they will be less exposed to the sun, but must only be shaded with a light material during the hottest part of the day.

Ferns are now growing fast, and must be well supplied with water at the roots and have increased atmospheric moisture. Tree Ferns should have the stems syringed twice a day, being careful to see that the roots at the bottom of the pots or tubs do not become too dry, as the surface may appear wet. If the pots or tubs be small, healthy vigorous plants will require water twice a day.

#### CALENDAR OF OPERATIONS IN THE APIARY.

##### APRIL.

FEW seasons would show more clearly the advantage of a special calendar than the present one. The lateness is here extreme, the temperature low, and the "weather forecast" not encouraging. In early springs Peach blossoms have been open on a south wall of ours on March 1st; but now, April 4th, the fully swollen buds are yet waiting for a change before expanding. The present danger is from two sources—shortness of food in the hive, and over-haste in the bee-keeper; and that the latter is not imaginary is evident, as we have already been asked whether it was not fully time to force swarms and divide for increase. In regard to food, do not suppose that combs fully stored and sealed and quite outside the brood nest will keep bees breeding. These combs indeed are, unless used by the bees, a hindrance rather than a help, as they cool the colony by obliging the hive to be left larger than would otherwise be necessary. Such combs may be uncapped, when the bees will be stimulated by removing their honey into more central portions of the hive, but the majority of colonies will be found now to have empty combs on the outside of the cluster, and judgment will be required in determining whether these had better be removed or no. If empty and not im-

mediately needed either for store or brood they had better be removed, as they actually cause a consumption of honey for heat-production by their presence, while as the bees increase and expand, as they presently will with more genial weather, they can easily be restored. Of course, all depends upon varying conditions. My colonies are now generally densely packed in seven frames, and such could not be contracted; indeed, a rising thermometer will demand for them new frames in quick succession.

FLOUR CAKE should still be given and the supply kept up, when breeding will not be relaxed; but in the giving of liquid food during such biting wind as is now prevailing it is important that the supply should not be continued during the day; or the bees, learning that store is really being found somewhere, will surely fly abroad to be chilled and destroyed in large numbers, while those that do return will do so empty and exhausted. I have the last week been especially trying syrup-feeding upon two stocks, giving twenty others flour cake; the latter have all been quiet, flying for water and artificial pollen, as the weather has seemed to warrant, while the former have been in continued unrest. The owner of skeps should especially remember that as the winter has disposed of the honey of the previous season, while brood-raising now requires a good income to make both ends meet, feeding is increasingly essential in unfavourable weather. If this be forgotten the bees as the pinch comes stop raising brood, while they suck the juices from the larvæ, and tear the chrysalides from their cells and eject them from the hive. When these are seen they are sometimes described as "white bees;" but this sign of starvation does not present itself till immense mischief has been worked and the profitableness of the stock reduced probably for the whole season. Instant feeding is in such cases the remedy.

Queenlessness may be suspected if stocks carry few and small pellets of pollen while others are busy with large well-formed loads. Should the owner of a queenless colony, which is also a fairly strong one, be also unhappy enough to possess one having foul brood, it will be wise to give a frame of brood to the queenless lot from some other healthy colony a week after destroying carefully all queen cells, and then caging the queen from the diseased stock upon the brood comb and liberating her in two or three days in the usual way. Uniting is, however, the best course in most cases of queenlessness. Artificial pollen is yet of immense service, and my bees are taking it greedily at every opportunity the weather gives. Water is very important, and much bee life is spared if the foragers have an unfailing supply at hand. When honey is being freely gathered it is at once food and drink, but in dry east winds water is essential, and the drinking fountain will then be the best frequented spot in the apiary.

Those who intend raising queens of any special race in advance of the usual season so as to favour pure impregnation should insert a frame of drone comb in the midst of the brood nest of the colony intended to supply the drones. Robbing is likely to occur if there be any untidiness with the syrup. Spilling a few drops about a hive when honey is scanty brings a host of inquirers, and often they get inside what they have failed to secure without. Contract the mouth as a remedy, and especially try giving to the entrance the form of a narrow tunnel.

Section crates, guide combs, foundation strips, and all the paraphernalia of the busy season should be prepared at leisure while transferring, and all work of this kind had better be deferred till next month. I shall be happy to show my stocks to those who are interested.—F. CHESHIRE, *Avenue House, Acton.*

#### THE BEES OF THE ISLAND OF CEYLON.—No. 2.

##### A JOURNEY TO THE INDIES—IMPORTATION OF CYPRIAN AND HOLY LAND BEES INTO INDIA.

(From the "Ceylon Observer," January 28th, 1881.)

It was a long journey that brought me from the island of Cyprus to this place. Several hundred miles of the Mediterranean Sea had first to be crossed, then after a short delay at Port Said the Suez Canal was passed, and our steamship the "Sindh" of Marseilles entered the Red Sea. Six days steadily she bore southward, greeted only by shifting hot desert winds. For a time Mount Sinai looked down upon us, then we saw no land until we neared the Strait of Bab-el-Mandeb. At Aden the anchor was cast; but as our stay was to be of only a few hours' duration, I could not think of giving the bees I had brought with me a chance to fly, though they had "worried some" under their confinement during the Red Sea journey. I landed in hopes that by going to the town of Aden, some three miles distant, I might find some bees. I was told that it was seven days' journey to the region where there were any tillable lands, and no one knew where there were any bees. Although our steamer was a fast mail boat we were as long going from Aden to Ceylon as it often takes to cross the Atlantic Ocean. The journey seemed all the longer to me, as there were many thousand tiny voices pleading for liberty. The officers of the ship afforded me every facility available to insure the safety of my charge, but the heat of the torrid zone was severe, and though the shipping boxes were well provided with wire-cloth ventilators, nothing but a flight would benefit some of the colonies; it was, therefore, a gratifying sight when the rich Palm-covered island of Ceylon rose as it were from the dreary waste of waters.

As soon as I could I unloaded my precious freight and proceeded to secure a place to stand the bees for a flight. I obtained the

privilege of putting the hives on the back porch of an unoccupied house, and the little immigrants from Cyprus and the Holy Land were soon making the air resound with their humming. I found to my joy that every queen was alive and most of the colonies in good order, those to which I had given sugar and water during the latter part of the journey having commenced brood-rearing. The colonies in the best condition were those whose food up to the last few days of the journey had been wholly honey in the comb and whose hives contained 850 cubic inches, into which four frames 9 by 10 inches had been placed. Of course I was eager to see the bees of Ceylon. From all previous accounts I was led to suppose that *Apis indica*, a small bee, and *Apis dorsata*, a very large bee, existed in Ceylon. From the moment I landed I made inquiries as to where the bees were to be found, but the reply invariably was, "Only in the jungles." No horses could be obtained, and carriages go but a short distance from the town; so, staff in hand and a man to act as guide and interpreter, I started for the jungles. We had only travelled about an hour and had not yet reached the jungles, when a native in the dress of the poorer people—simply a cloth about the hips—volunteered to show us a tree containing bees. He brought us to a large Cocoa-nut Palm, and about a dozen feet from the ground honey bees were flying in and out. Very strange-looking and very swift-winged little bees they were with loads of pollen and honey. I could not, for some time, catch one in my fingers, but at last I succeeded. Another tree containing the same kind of bees was shown us a few rods away. These were low down, and I put my hands into the hole and broke off a piece of comb. I could not but laugh outright at the tiny hexagonal cells, which suggested that these were only baby bees playing; they were real grown-up folks gathering honey and pollen against a time of need.

The new-found guide assured me through the interpreter that he could take us to a tree containing some of the large bees, which, however, turned out to be hornets. There are contradictory reports regarding the existence of a race of large honey bees in the interior of the island. Everyone has noticed that in general our large humble bees pass the smallest flowers unvisited, and white Clover amongst others, which we know contains much honey. Now just as the idea has come to me that if we could secure a large race of honey bees, such as is perhaps *Apis dorsata*, which could obtain honey from red Clover and other large blossoms, we should find it a great gain to apiarian interests; so, also, I have wondered if the smaller race or sort would not collect the honey which must be found in the tiny blossoms and more accessible to the small bees alone. I believe there are possibilities in this direction quite worthy of consideration, and that the two sorts might be kept in the same locality with no detrimental division of the field. Already I have observed that my little friends of Ceylon do not scorn very humble blossoms upon which I have never seen our ordinary-sized honey bees. Some of these small blossoms are very rich in nectar. To sum up, then, I would say that I believe the probabilities are in favour of the newly acquired bees. I do not mean to say they can or will supplant our other bees, but only that it seems likely they can be profitably raised in those countries—possibly in the same apiaries—where other races of bees are kept. They may be somewhat inclined to rob other hives, but as regards their own disposition to collect honey and pollen, the prolificness of the queens, the great beauty of the bees, the fact that the drone comb made by this race can be used as worker comb in our hives of ordinary bees, together with the great ease, rapidity, and safety with which they can be manipulated, are certainly strong points in their favour. Should I succeed in transporting to my native land (America) living bees of this species alone I shall feel that my stay in Ceylon has not been in vain, for even if they should not prove to be of great practical value, still their introduction will help to increase our knowledge of apiarian science.—FRANK BENTON, *Point de Galle, Island of Ceylon.*—(Communicated by Alfred Neighbour.)

**Books** (*A. N. Hansen*).—All the works you name can be had from this office post free for 4s. 8d. sent to the publisher. The Rose you name is not grown in England under the name of Queen Victoria, but may be on the Continent. On this point you may obtain information from the author of the article to which you refer, and whose address is incorporated therewith. Relative to this subject we have received the following from an eminent amateur rosarian—"re an international Rose election. Teas Souvenir d'un Ami and Queen Victoria surely are not synonymous. There is a well-known H.P. Queen Victoria, and I remember many years ago having a Bourbon climber of that name. Manifestly there must be some mistake about the latter. The results of the poll are a little inaccurate otherwise—to wit, Which five H.P.'s are the freest and most abundant bloomers for the summer? La France, Jules Margottin, Général Jacqueminot, and two others our friend Mr. Hinton would hesitate at admitting—Bourbons Souvenir de la Malmaison and Louise Odier (Madame de Stella). Then, again, the ten novelties from 73 to 78 are mentioned by name. I do not think an Englishman would have chosen them without 'the slightest hesitation;' but foreigners do these things differently. Still they should be accurate.—C. H. B."

**Double Cyclamen** (*W. H. Manser*).—Your flower is to a certain extent novel, but it is quite a matter of taste whether a variety having more than the

normal number of petals is more attractive than large-flowered single forms with broad smooth petals. But although your flower is novel it is by no means the first of the kind that has been sent to us, as we have seen flowers with a greater number of petals than in the example before us. Double flowers are, however, not numerous, and your variety is worth preservation.

**Designs for Carpet Beds** (*C. Lamb*).—You will find designs such as you require in the following numbers of this Journal, which may be obtained from the publisher, post free 3½d. each:—Nos. 910, 914, 916, 918, 932, 939, 940, 945, 995, 996, 997, and 999. There is also much information upon the subject, with numerous plans, in the "Royal Parks and Gardens of London," published at this office, post free 5s. 5d.

**Auriculas in Yorkshire** (*J. L. Herts*).—Mr. Douglas's descriptions of Mr. Horner's Auriculas at Kirkby Malzeard, and Mr. Simonite's at Sheffield, are included in Nos. 790 and 791, the issues of May 18th and 25th, 1876. The numbers can be had from the publisher, price 3½d. each. The subject is not continued in other numbers, but you will find an article on the Auricula by Mr. Douglas in the same volume on page 325, No. 787. If you will state your missing numbers we will inform you if we can supply them. If an Auricula is unhealthy and not showing bloom we should at once remove carefully most of the old soil from its roots, and if these are not in good condition we should place it in smaller pot well drained, in a compost of sweet turfy loam and a liberal admixture of crushed charcoal.

**Grapes not Setting** (*W. C.*).—In your cold and exposed position you have not the means for providing the necessary amount of heat for succeeding with Muscats and the other late varieties that you name when the Vines are started in December. That your treatment is good is evident by the state of the Foster's Seedling and Black Hamburgs, and we think that under the circumstances you have done well to secure a good crop of these. As early Grapes appear to be important, the house ought to be divided, the late varieties being grown in one division, the early ones in the other nearest the boiler. In this case a little addition would be required to the piping, with the necessary valves for admitting the heat when requisite into the second division. By this arrangement you will succeed better with both early and late Grapes. The latter ought not in your case to be started before February.

**Hubbard's Squash and Butter Beans** (*Thomas Harris*).—The former vegetable has been grown in many British gardens, and seed used to be offered in some seedsmen's catalogues. We have grown it, but its quality was not generally appreciated. Butter Beans are regularly cultivated in this country, and may be had from nearly all seedsmen. Thousands of Castor-oil Plants are grown in England yearly for decorative purposes, notably in the London parks, but you are in error in stating they are quite hardy. They grow freely during the summer, and occasionally flower in the autumn in England, but the frost usually kills them before they arrive at the flowering stage.

**Marechal Niel Rose Sporting** (*E. M.*).—It is not unusual for flowers more or less tinted with rose to be produced by this variety. Many similar to yours have been sent to us from time to time. We are unable to state the cause of the change, but it is not caused by the sun nor from any error in culture.

**Boxes for Packing Peaches** (*An Inexperienced Lady*).—We use boxes made of half-inch deal, 12 inches long, 10 wide, and 3 deep, all inside measure, sufficiently large to hold a dozen of the largest fruit, and proportionately more of those of less size. The fruit is first wrapped in tissue paper, and then in cotton wadding. A little bran is placed in the box sufficient to cover the bottom about half an inch thick, the fruit being then introduced, and the interstices between the fruit filled with bran, quite filling the box with that material, the lid being put on and secured with screws. It is important that the fruit be very carefully handled and packed tightly in the boxes without pressure on the fruit. We send a great number packed in this way every year nearly three hundred miles by rail, and they invariably arrive in good condition. Any carpenter can make the boxes. The boxes may be made larger to accommodate a greater number of fruit, but we prefer the size given, and place them in another larger box with moss or other material about them to prevent their moving in transit.

**Pea Hurdles** (*Idem*).—Wire Pea hurdles are not only neater but quite as effective as Pea sticks, and last many years. They are, however, rather costly, as they require to be placed on both sides of the rows of Peas. They may be had from those advertising wire netting and Pea guards in our columns. We cannot depart from our rule not to recommend dealers.

**Vines Dying** (*G. C.*).—It is probable that the Vines, being planted outside, have had the stems frozen and their tissues destroyed, so that the sap cannot ascend, in which case they will push fresh shoots from near the base if there are any dormant eyes. There may be local causes that have conduced to the death of the Vines irrespective of the frost, which, however, we think the most likely cause from the severity of the winter and the inefficient protection of the stems. Probably those that are "looking very well" have had more efficient protection for the stems. Overcropping is a great evil, and if long continued causes complete enfeeblement and not infrequently death; in fact, from the Grapes not colouring well last year it is clear they were either overcropped or were not in good health. Afford in future more efficient protection for the stems in winter, and mulch over the roots with litter to protect them from frost, especially about the collar. Encourage more foliage, and crop moderately, and those that are "looking very queer" will in all probability improve.

**Flower Garden Arrangements** (*C. G. S.*).—An effective and harmonious arrangement may be made by planting in the large central bed 7, *Vesuvius Pelargonium* with a broad edging of *Marechal McMahon*. The four corner circles 1, 1, 1, 1, *Crimson King Verbena*; edging *Golden Feather Pyrethrum*. Four central circles 3, 3, 3, 3, blue *Lobelia*; edging *Crastium tomentosum*. Long beds 2, 2, 4, 4, broad central stripe *Christine Pelargonium* with a stripe of *Flower of Spring* or *Bijou* on each side; edging *Iresine Lindenii*. The flowers to be kept picked off the white variegated *Pelargonium*, the required colours being pink, white, and crimson. Long beds 5, 5, 6, 6, central stripe of *Scarlet Pelargonium Tom Thumb*, with a stripe of *Purple King Verbena* on each side, and *Mrs. Pollock Pelargonium* with the flowers kept picked off outside, the colours required in these beds being scarlet, purple, and yellow. The plants you have will, however, afford greater variety if required; but do not plant the beds in pairs as you propose, rather repeat the same arrangement in opposite corners 5, 6, or 2, 4. The circles 3, 3, 3, 3, should in any case have soft tints or neutral colours to break and subdue the brighter tones of the long beds. *Iresine* when used for an edging must be kept pegged and pinched. *Echeveria californica* may be used outside it, but as your beds are probably small it will be better to keep to single edgings. If stripes are not liked for the long beds, have simple masses of one colour in them—there might be *Christine Pelargonium* edged with *Flower of Spring*; *Purple King Verbena*, edged with *Mesembryanthemum cordifolium variegatum*; *Marechal McMahon*

Pelargonium edged with dwarf blue Ageratum; and Bijou Pelargonium edged with Lobelia.

**Tank Heating (E. C.).**—The mode of conveying hot-water pipes through tanks in horticultural structures is not done with the object of "excluding frost," but when the tanks are covered for affording bottom heat to plants and crops, such as various kinds of stove plants, Cucumbers, Melons, Pines, &c.; when open for maintaining a warm and very moist atmosphere in houses devoted to the culture of aquatic plants. For affording top heat hot-water pipes must be exposed in convenient positions, and in quantity in accordance with the temperature that is required by the plants or crops, and governed also by the height and exposure of the house. The subject of heating horticultural structures is referred to in its various phases by Mr. Fawkes in a new work that has recently been published. It can be had from this office, price 10s. 6d., post free 11s. 2d. Tanks are not suitable for heating greenhouses.

**Bone-meal (Inquirer).**—We do not remember having published a special article on this subject. The value of bones in various forms as a manure is admitted, and bone-meal has been frequently recommended in our columns as a good and safe manure for plants and crops. We extract the following from our small manual "Manures for the Many" (post free 3½d.).—"All bones contain more than half their weight of phosphate of lime, and are beneficial as a manure, because that chief constituent phosphate of lime is also a constituent of all plants; and the gelatine which is also in bones is of itself a source of food to them. The bones must be applied to the crops in very small pieces, or in powder; and 10 lbs., at the time of inserting the seed, are enough for 30 square yards, if sown broadcast; and a much smaller quantity is sufficient if sprinkled along the drills in which the seed is sown. There is no doubt that bone-dust may be employed with advantage in all gardens and to all garden crops; but it has been experimented on most extensively with the Turnip and Potato, and with unfailing benefit. Mixed with sulphur, and drilled-in with the Turnip seed, it has been found to preserve the young plants from the fly. Mr. Knight found it beneficial when applied largely to stone fruit at the time of planting; and it is quite as good for the Vine. To lawns the dust has been applied with great advantage when the grass was becoming thin. As a manure for the shrubbery, parterre, and greenhouse, it is also most valuable; and crushed as well as ground, is employed generally to mix with the soil of potted plants." The value of bone-meal has been rendered in the following expressive and suggestive verse, which students in schools of agriculture might well commit to memory—

"No bone-dust, no Turnips; no Turnips, no Wheat;  
No Wheat and no Turnips, no cattle, no meat;  
No Turnips, no cattle, nor manure in the yard,  
Make bills for the doctors, and farming go hard."

**Espalier Fence (Deodar).**—There is no objection whatever to the bar fence you propose to erect. We know similar fences that have been erected half a century, and they are furnished with splendid trees. The height of the fence is very much a question of taste and adaptability to position. We have seen them of all heights, from 4 to 10 feet. A height of 6 feet makes a fine fence, the lowest bar being 15 inches from the ground, and the highest near the top, with five other bars at equal distances between. By this arrangement you will have seven branches on each side of your trees. A 5-foot fence, which is a good and useful height for espaliers, would afford the means of training six branches from each side of the trees.

**Varnish for Iron (Baillif).**—The following has been recommended, which we publish, as you request us to state a mode of making what you want; but we advise you to do as we do—purchase the varnish that has often been advertised in our columns, and which is inexpensive and good. To make black varnish:—One gallon of coal tar, half a pint of spirits of turpentine, 2 ozs. of oil of vitriol, stirred, and laid on like paint. Mix with a piece of wood or stick the tar and vitriol, and then add the turpentine, and apply it with a brush. Mix no more than you can use at once, and then apply it as it becomes thick.

**"Can a Boiler Explode when the Flow is only a Quarter on?"**  
(An Under Gardener).—This is an important question, and your case is a common one—namely, that of a boiler, &c., to heat a conservatory, and coils of pipe in the mansion so arranged as to be heated separately or together, as is clearly indicated by the directions on the board by the valves, which states "that the valves of one circulation are not to be shut unless the other circulation is open." This means that the water must have means of circulation or the boiler must, from the expansion of the water in heating, explode. Instructions of this kind are rarely given, but they are highly necessary for those stoking, many young men not being acquainted with the principles of heating by hot water; indeed, we have more than once known a boiler heated by the fire with all the valves closed, and the water from its expansion making the boiler move in its place. If it had not been noticed soon enough there would have been an explosion, not more perhaps than to have attributed the disaster to a flawed plate, bad rivetting, or the boiler not being properly constructed, when in fact the real cause of injury would have been ignorance or neglect on the part of the stoker. Instructions of the kind named above ought to be in every stokehole where the boiler heats more than one compartment separately or together, and if attended to many a breakdown would be averted. As to the complaints about the heat in the mansion not being regular, that depends entirely on the stoker, although he may not know the heat other than as you state by feeling the pipes. If the pipes are hot either the coils are not sufficient for their purpose or more heat is wanted than can be had from hot water, but we do not think this is exactly what is wanted. Heat is wanted in the mansion, and none at the same time in the conservatory. Why should not the coil pipes be worked so as to heat the mansion when heat is not required in the conservatory? Surely heat is not to be expected without fire, and as no heat was required for the conservatory it appears to have been supposed that none was required for the mansion. This appears to us as if inviting complaint, for what sun would do for a conservatory it would not for a mansion, it not passing through walls the same as through glass. We now come to your point. The heat was turned entirely off the conservatory, the "fire was checked, the draught shut off, and the house circulation valve turned about a quarter of its full distance." We do not wonder that on telling your chief what you had done he stated "you were running a great risk, as the hot water having a large body of heat round it must have vent somewhere." Clearly you did not follow the instructions on the board, as "one valve was not to be shut unless the other was open." The furnace was at its full heating power or near thereto, hence the checking of the fire and draught, and the house circulation valve was only turned on a quarter, whereas, as no heat was wanted in the conservatory, it should have been turned on full. With a "quarter on" it was straining the boiler by diminishing the waterway, and were there a weak place in it, it was a sure method of finding it. It was no use checking the circulation of the water to keep down the heat in the mansion, for it would rush through the "quarter on" rapidly; for as your chief truly stated, "it must go somewhere," and if it could not get through fast enough then must come an explosion, the boiler plates or surface being unable

to resist the pressure. We are glad of the opportunity of stating our conviction that more breakdowns occur with boilers through inattention to the requirements of a free circulation of the water than to what our correspondent has been led to conclude, as many others have done—viz., "driving very hard." If a boiler will not do its work without being driven, the sooner it is taken out and replaced by one that works properly the better. There is nothing so wasteful about a garden as boilers requiring to be driven, as in that case more heat escapes from the chimney than is abstracted by the water.

**Plants for Name (W. H. W.).**—Our rule is not to name more than six specimens at the same time from a correspondent. These must be in good condition and fair examples of the species. Flowering plants can only be named from flowering sprays, and Fern fronds must have spores. When sprays of shrubs and trees are sent, some particulars of their habits must accompany them. Specimens always arrive in the best condition when packed with a little damp moss and sent in tin boxes. Sprays simply enclosed in letters arrive every week, and the majority of these are either so much crushed or withered as to render it impossible for anyone to determine their names. In some cases a piece of the root of flowering plants, if it possesses any marked characters, is a great assistance in naming the specimens.

**Names of Plants (S. B.).**—1, *Cypripedium barbatum*; 2, *Sedum earneum*; 3, *Adiantum assimile*; 4, quite shrivelled. (A Young Gardener).—The spray and cone are of *Pinus Pinaster*. (Mrs. C. Edwards).—*Iris fimbriata*. (Acron).—The spray is quite insufficient for identification.

#### COVENT GARDEN MARKET.—APRIL 6.

#### POULTRY AND PIGEON CHRONICLE.

#### THE UTILISATION OF WASTE LAND.

(Continued from page 263.)

LET us compare the advantages of planting after a well-made fallow and that of digging holes in a hard and untilled surface. In the former case the trees would root quickly and spread under ground without difficulty during the whole period, until they may be felled whilst young or left for maturity as timber. In the latter case, however, when planted in such strong land, with merely holes dug to take the trees, it will prove the grave of the far greater portion, and any which may survive never can make a profitable growth, nor can the untilled surface be horse or hand-hoed, so as to keep the land clear and free from weeds. We therefore assume that the cost of fallowing is money well expended, and without it the land had better be allowed to continue in the same wasteful state as before planting had been decided upon. As it may be desirable in the opinion of some landowners to plant Firs only for a crop of ripe timber, we beg the reader to refer to the article upon this subject in this Journal dated the 6th of May, 1880. In following up the subject of quick returns, however, we will refer to the close system of planting as before stated, in which case the small ridges we have named of 10 feet wide will

be just suitable for bearing four lines on each ridge. In each alternate row every other plant is spoken of as being planted with Ash; but as the growth of Ash would be slow and unsuited to heavy land we must find a substitute if it is intended to retain a plant of underwood for future profit; we therefore consider that Sweet Chestnut would be well to take the place of Ash on strong soils, especially as it is easy to obtain the plants from the nurserymen. On the other hand, we have a strong idea that one or more sorts of wood well adapted for quick growth and valuable purposes may be made available instead of Ash or Chestnut trees. They would be more profitable, although it would be far more difficult to obtain plants unless they were raised direct from seed, as the trees we refer to are not kept in stock by nurserymen except for sale as ornamental objects, and in consequence could not be purchased in a wholesale way, or in quantity for extensive planting, except at a price which would be prohibitory for profitable growth. We shall, however, in continuing the subject refer to this matter at some length before concluding our observations. After the Firs and underwood trees are set upon small ridges they will with deep furrows throw off the water quickly. Whether the land has been previously pipe-drained or not, cross open water carriers will be required to take the water away quickly, and these should be 30 inches wide at top, 18 inches wide at bottom, and 30 inches deep. This will be necessary under any circumstances, because pipe drains will not act long in woodland.

We have previously stated that we should refer to sorts of trees capable of being grown to produce either timber or underwood upon such soils as may be too strong for the common Ash to flourish upon as they do upon light and poor soils. The first tree we will notice is not used to our knowledge in plantations generally, either for growth as timber or underwood. We, however, very well remember when the Locust Tree of America was introduced to public notice by the celebrated William Cobbett, and was recommended by him in his "Weekly Register" in 1823. As he had a great many of these plants for sale at that time we shall notice some of his statements as to the value of the timber and wood, the purposes for which it is adapted, and the mode of raising and planting the trees.

The Locust Tree of America is *Robinia Pseud-acacia* or Bastard Acacia, sometimes called Thorn Acacia, and it is found in most nurserymen's catalogues under one of these names. Up to the present time we suppose it has only been grown as a shrub or tree for ornamental purposes. As, however, we have reason to rely upon the statements made by Mr. Cobbett and other writers in America who have recommended its being extensively planted in England, we shall make some quotations from the "Register" dated 1823. After stating that he had a hundred thousand Locust plants for sale at a price named he says, "They require a strong loamy soil; the land should be moved at least 18 inches in depth, keeping the best soil on the surface, and in planting for profitable growth the plants should be set at 4 feet apart each way." He further says that his "first sowing seeds of the Locust Tree was in 1806. Some of the plants raised were set out in 1807, 1809, and 1813, close by the village of Botley in Hampshire; and those trees planted in April, 1807, after seventeen years' growth were from 38 to 42 feet in height, and were from 60 to 68 inches round at the base. Those planted in 1809 were in the same proportions of growth at fourteen years, whereas those trees planted in 1813 and raised from seed sown in 1812 at eleven years' growth varied from 37 to 40 feet in height, and from 32 to 38 inches round at the base." When these trees were cut they were seen by a friend of ours, who last week told us that they cut up remarkably solid, being all spine, without any sap as is seen in our native Oak wood, and the wood of a light and bright brown colour, something like Box wood. The height and girth of these trees shows at once the extraordinary growth which they will make when properly planted

and cared for, and it seems that at any age or size the wood is of the same enduring quality—a matter of immense importance in estimating the value of underwood; and it is stated that Locust wood for hop poles would last for a long period without requiring fresh pointing; in fact, Mr. Cobbett says the wood is very durable.

Of the writers in America the first was Judge Mitchell from Long Island, who states that posts to a fence taken up after standing twenty-eight years were as sound as ever in parts underground as well as above. Mr. Henry Lawrence certifies that a post which he knew for forty-four years was perfectly sound, both above and below the level ground, when removed, and that he remembers hearing his father say that it was an old post when he knew it, and it must have been there for upwards of eighty years. Mr. Daniel Smith certifies that a post placed 2 feet under ground by his ancestors in the year 1709 was examined in October, 1820, and found to be without the least decay; this information was obtained by Dr. Peter Townsend of Smith's Town, Long Island. We have abundance of evidence as to the durability of this timber, and also as to its rapidity of growth and its being suitable for every purpose to which wood is applied, including hop poles, hurdle gates, pail fencing, boarding, and for all sorts of posts, doors, floors, and sills, &c., which may be required on the farm premises or elsewhere. We have nothing growing in this country as timber or underwood which can furnish such value as this for all and every purpose at any age of the wood—not even the heart or spine of the best Oak comes near it in endurance; and as regards early maturity, we have nothing known yielding the same quality in so short a period. As we are quite unable to disprove the evidence here given we cannot do otherwise than to recommend the growth of the tree in preference to Ash or any other description of wood. It must, however, be raised from seed for the special purposes of planting, because it cannot be obtained from the nurserymen except at prices which would make the charges of planting objectionable in every respect.

We will now take up the question of management after planting. We do not, however, insist upon the method of growing it in conjunction with Larch Fir, although no doubt it may be done with advantage. We should prefer to make a plantation entirely of Locust Trees, and when planted at 4 feet apart each way on a fallow and prepared surface as previously described, with proper horse and hand hoeing, they would make the most rapid progress. It is stated that after the trees have taken well they should be cut down close for producing underwood, as two stems may be left for the growth of poles to be cut early; but for trees a single stem only should be left. It is, however, confidently stated by Mr. Cobbett, and we hope this will be tested, that a plant cut close in the second year will become of much larger dimensions and active growth at the end of any given number of years than that which had grown direct from seed without cutting or mutilation in any way. We have seen various other kinds of trees recommended for planting, such as the White Oak (*Quercus alba*); however, when we have compared them with the American Locust we decide immediately in favour of the latter. No doubt this underwood would be very valuable, because if we grow two hop poles to each tree fit for use and sale in seven years the number of plants per acre at 4 feet apart each way would be 2720, so that by taking two poles from each plant we should have for sale 5440 poles, worth, compared with Ash poles, at least 6s. each; we have only to deduct about 6 per cent. for failures and crooked poles (the latter being fit for trunnels, used in ship-building), leaving not only a large return, but a quick one.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—The sowing of Barley, Oats and drege, and the planting of Potatoes and Cabbages, have been continued lately without much hindrance; at the same time we must not neglect to consider the importance of sowing the Lent corn with Clover and grass seeds, and the young Wheat also where it has been sown after Potatoes, Mangolds, or early Turnips: in the latter case we have always succeeded with broad Clover. The chief point to be observed is that the seeds shall be alternated, for when the land is cultivated either under a four or five-course rotation, it is necessary to avoid sowing the same kinds of seeds as were grown in the previous course; for instance, if broad Clover and Alsike with some Saintfoin mixed were grown before, white Clover and yellow Suckling should now be sown except when the land is intended for two or three years' lea, the seeds then required being white Clover 5 lbs. per acre, Alsike 5 lbs., Timothy Grass 6 lbs., Cocksfoot 6 lbs., and Pacey's Perennial Rye Grass 10 lbs. By either of these changes broad Clover will not occur oftener than once in ten or twelve years. It is very necessary to recollect that broad Clover fails very frequently when the land has borne a similar crop in the former course, and it is a common observation amongst farmers that the land has become Clover-sick. This is an expressive term, but it by no means indicates the cause of failure, which has recently been

attributed to the fact of a full crop of broad Clover having previously absorbed a large portion of the manurial elements in the soil necessary for the production of the crop, and this accounts for the failures in succession that are often seen. Upon the hill farms, and those without any pastures or water meadows, where a stock of breeding sheep is kept, some land may have Italian Rye Grass sown in the Wheat, for although Mangolds may be considered specially adapted to prevent scarcity, yet Italian Rye Grass and Rye itself sown in the autumn are first-rate provision when the spring food for sheep and cattle is short. The land where Rye Grass has been fed off may be ploughed, pressed, and sown with Rape or Thousand-headed Kale; that which has been occupied with Rye fed off in conjunction with Italian Grass will be suitable for Mangolds or Swedes after once ploughing. If, however, it is foul with couch the green crops must be superseded by a naked fallow before sowing the seeds for root crops.

**Hand Labour.**—Men and women are now employed in timber cutting and stripping off bark from the Oaks, the women setting up the bark. All other timber, such as Elm and Ash, have been cut during the winter, especially for the purposes of repairs; it is also advised by many, and we approve it, that the Oaks when required as timber for the home farm should be cut in the winter months before the sap has risen, and consequently without taking off the bark. Men are now much required in connection with the various kinds of farm work going on, such as preparing manure for Mangolds and the late kinds of Potatoes. The women may be employed in cutting the Potato sets, for we agree that they should be cut before setting, so that not more than two eyes are left on each set, unless in the case of some sorts, especially the early ones, which have but few eyes. In those sorts, however, which show a large number of eyes the planting of small Potatoes are objectionable, because they produce numerous stems forming quite a bunch of leaves. We prefer to have one or two strong stems only.

**Live Stock.**—The dairy cows should now go out on the pastures at daytime chiefly for airing, for as yet there is but little grass on the best pastures, but returning to the stalls or courts at night, and there receiving their allowance of artificial foods, chaff, and roots mixed, and if with malt to make it attractive as well as forcing the milk so much the better. The home farmer may now with advantage have his middling or inferior Barley malted at a cost of about 4s. 6d. or 5s. per quarter, and by the increase in bulk as well as quality secure an article for various purposes of increased value as compared with barley meal. We must caution the farmer against allowing dairy cows or store cattle to feed on any pastures which are intended to be laid up and cut for hay, as all such should be laid up and rolled not later than the first week in April. Swine require particular attention, for it is not customary to arrange for the sows to farrow about March or April. The young pigs will then have the advantage of favourable weather, but it is dangerous to allow pigs under twelve weeks old to eat Mangolds promiscuously in the yards whilst being kept only in store condition, as they often die unexpectedly, and are found to have the lungs decayed. Of course if a fair allowance of meal is given and mixed with pulped Mangolds they will do very well. The closing of markets in various districts has been a great source of inconvenience to the home farmer in the sale of his stock, whether in a fat state or merely in store condition. In most districts, however, the foot-and-mouth disease has nearly disappeared, although this disorder seldom occasions death, and rarely lasts beyond a few weeks in the herd, yet the future loss and disturbance of health of the animals in consequence never can be calculated, and is often very serious; it is therefore necessary that it should be stamped out by isolation as quickly as possible. The manner in which the sheep are attacked and the estimated condition of the animals is often very unsatisfactory, because the symptoms of foot-rot attended with internal fever is often mistaken for the foot-and-mouth disease.

### VARIETIES.

**AGRICULTURAL PROSPECTS.**—The cold days and frosty nights of the past week have not improved the appearance of growing crops of any kind, and all vegetation remains very backward. The open weather, however, has enabled a great deal of work to be done on the land, and Barley sowing has been pushed forward very rapidly on light soils and loams. On the heavy lands the surface has been getting very hard during the last few days, and, with the exception of fallows made before Christmas, the clays are very troublesome to work, the cold wet clay turning to brick under the drying winds. A warm shower or two would now do great good to the land and all the crops upon it, for nothing seems to grow; in fact everything seems to be getting smaller day by day. Winter Beans make but a poor showing, and the average of spring Beans planted must be a very small one. Peas, too, have gone in on a small acreage, because the season was late and other work was pressing. Keep of all kinds is now very scarce, and stock are being turned out prematurely in many districts: this is bad policy in every way. Store cattle are generally in rather low condition in England and Scotland, but in

Ireland they have wintered well and come very fresh to the spring fairs. Sheep are not doing very well, as they are mostly on short keep, and the lambs do not get as much from the ewes as they require. In fact, the liberal use of feeding-stuffs has again become a necessity which may not be neglected with impunity.—(*Mark Lane Express.*)

— **THE ADULTERATION OF DAIRY PRODUCE.**—We are glad to observe that attention is being directed to the alarming extent to which the adulteration of Irish butter is being practised. Adulteration of all substances is not only a dishonest, but it may also be a dangerous practice, and those who carry it on should be subjected to severe punishment. We regret that latterly there has been only too good reason to believe that the adulteration of butter by oleomargarine or butterine is being perpetrated extensively in different parts of Ireland, more especially in the larger towns. More than one public body throughout the country have petitioned Parliament on the subject; while at a meeting of the Council of the Royal Agricultural Society of Ireland last week, the Rev. Canon Bagot referred to the matter with the view of pressing it upon the attention of the authorities in Dublin.—(*Irish Farmer's Gazette.*)

— **OLEOMARGARINE.**—Much is heard of this substance, and the following, which has been published relative to it, may not be devoid of interest:—"Oleomargarine, which is derived from beef caul fat, the average yield being 35 per cent. of the fat used. This product is used in America both for the adulteration of butter and for the manufacture of butterine or counterfeit butter. It is also largely exported to the United Kingdom and to Holland for the purpose of adulterating butter in those countries. 2, Suene, made at Chicago, and consisting of 50 per cent. of hog's lard, and 50 per cent. of western dairy butter. 3, Butter on a soapstone basis, which consists of a large admixture of the mineral known as 'soapstone,' which is ground to an impalpable powder, and is used as filling to make weight in flour, sugar, soap, paper, and many other articles, as well as in butter and cheese. The Food Adulteration Act is not sufficient to meet the requirements of this new traffic, or, at all events, its provisions are habitually evaded."

— **THE USES OF MAIZE.**—During his Budget speech last Monday night Mr. Gladstone spoke as follows on this subject:—"I wish to give a little detail about the case of Maize, because it is an interesting illustration of the mode in which, where freedom is given to industry, private enterprise discovers methods of making that freedom gainful. Maize was considered somewhat hard for brewing, and it was also found, when the experiment was seriously made, that it contained too much oil, which was a very grave objection. But this further discovery was made, that this excess of oil was not diffused through the general body of the grain, but lay entirely in that which is called the germ; consequently the wit of man thus provoked and stimulated extracted the germ from the grain and turned it to its proper account—viz., that of making oil, which we can burn in our lamps. The Maize, relieved of the excess of oil and now made suitable for brewing, was applied for that purpose; and I understand that the result is not only satisfactory as regards the beer which proceeds from it, but likewise it is satisfactory in this point, that the residue is found to be even more available and decidedly more profitable for feeding cattle than the residue formerly obtained from Barley."

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 203.)

#### GENERAL PRINCIPLES.

THERE are certain general rules or principles of breeding which have been ascertained to be correct by the experience of fanciers. A knowledge of these is indispensable to the beginner. During the formation of the strain these rules have to give way in some degree to the paramount object in view—namely, the establishing of a family, all the individuals of which bear a strong resemblance to a common ancestor, and are prepotent as to the points of that

ancestor. Even at this early stage these principles may frequently be applied, and later on they are all-important. Chief amongst them are those which relate to the influence of each parent over the qualities of progeny. First, as to size. Here it is universally admitted that the influence of the mother predominates. It is most important in breeding for size that the hen should be large and of a large strain. We do not for a moment suggest that a very undersized cock or cockerel should be bred from, but a cock of medium size mated with a large hen will produce a far greater proportion of large chickens than will result from the mating of a medium-sized hen with a large male bird. A very small bird of either sex should not be bred from unless the smallness has been occasioned by late hatching or under-feeding, and the bird is of special value for some other points. If the small bird be a very late-hatched one, and its blood is of special value, it had better be kept over until its second year before being used in the breeding yard. In most breeds the progeny of a bird which is small only on account of one of the above reasons will recover the lost size, but in such cases special care must be taken to give the chicks every advantage of early hatching and liberal feeding. Just as on the one hand, small size occasioned by what may be called accidental circumstances may be disregarded, so on the other hand extra large size occasioned by forcing the growth of the birds with much meat or other such food is of no advantage in the breeding pen. On the contrary, it has been found that these very large birds are frequently unproductive, or produce only weakly and degenerate offspring. Extra large size which has been produced by natural means is, where size is a point of merit, a distinct gain, and can if desired be perpetuated by in-breeding in the same manner as any other point.

Although the hen has the most influence over the size of the progeny, the influence of the male bird is also material, and it is much better where it can be managed to breed only from large birds of each sex, but if it is necessary to breed from a small bird on one side the above rule must be followed. The breeder should never mate undersized birds, no matter how produced, together, as this cannot fail to lead to a deterioration in the size of the strain.

When breeding, as in the case of Bantams and some varieties of Pigeons, for smallness, the converse plan must be adopted, and special care taken that the hen at least is as small as possible.

In general structure and shape the hen has also the most influence, but it must be remembered that this influence does not affect the cockerels amongst the progeny to such an extent as the pullets. The chickens of each sex show a tendency to inherit the properties of their ancestors of that sex, and although this tendency can be modified by the influence of the qualities of the other sex, still too much must not be expected. We may illustrate our meaning thus:—A Dorking breeder finds that his strain has a tendency to throw cockerels which are deficient in depth of breast. By selecting hens which are specially good in this respect to breed from he will probably find that nearly all the pullets inherit the form of their mothers and have deep breasts, but that the cockerels are affected to a much less extent, and that many of them are as shallow-breasted as their father was. Some few will show a marked improvement, but that is as much as can be expected from the process in the first instance. It is only by its repetition several times that the general character of the cockerels can be influenced.

The statement that the female parent has most influence in these points may be illustrated by supposing the Dorking breeder to attempt to remedy the defect indicated by merely breeding from a full-breasted cock with hens somewhat deficient in breast. Here it would be found that nearly all the chickens, as well cockerels as pullets, were deficient in breast, and if the hens were very bad in this respect the probability of getting a really good chicken of either sex would be slight indeed.

In regard to points other than size, shape, and structure, the male parent has the most influence, and nothing short of phenomenal excellence in any point in the hen can be relied upon to counteract in any degree a great defect in that point in her mate. Thus a cock with a very defective comb should not be used in the breeding pen if it can possibly be avoided. The chance of obtaining even one chicken with a perfect comb from such a parent would be infinitesimal, and both cockerels and pullets would be alike defective. A hen with an imperfect comb may, however, be bred from with a fair prospect of good results provided the cock mated with her be very good in this respect. Similar results will be obtained in regard to other fancy points, such as earlobe, colour, leg feather, and many others which might be mentioned.

The breeder must never lose sight of the fact that the issue of any given alliance take as much after their more remote ancestors as after their parents, and that this may modify very considerably

the results of the alliance. Regard must therefore be had in mating a pair of birds not only to their personal qualities but to those of their ancestors, and to the greater or less degree in which any particular quality has become developed and settled. Thus a bird which is defective in any particular point in which the strain generally excel may with safety be made use of where a precisely similar bird whose family were equally defective would have to be rejected.

Again, a bird which is of great merit in a point in which his ancestors were defective can only be expected to produce a very slight improvement in his offspring until in-and-in-breeding has been resorted to.

This brings us to a matter of some importance which cannot be too strongly insisted upon—namely, the general rule, that a bird defective in any material point should never be in-bred to. Such birds may be used with advantage for the purpose of strengthening a strain in points in which it is deficient, and they are of exceptional merit, but having served that purpose should not be used again. The converse of this is equally important—namely, that a bird which is of fair general excellence and of great excellence in any one point should be used as largely as possible in order to fix the good feature as a characteristic of the strain. It is only by thus seizing upon and breeding-in to what we may call accidental perfections, that the various breeds have reached their present respective high standards, and it is only by similar processes that any improvement can now be effected.

#### CROSS-BRED POULTRY.

"I AM a trifle puzzled with one sentence among the admirable remarks of your correspondent 'C.' upon cross-bred poultry. He mentions that two objects should be aimed at with cross breeds—viz., to produce good table fowls and good layers, and remarks that in the latter respect pullets 'as a rule' follow their mothers. If 'C.' can point out a single instance in which in this respect a pullet has followed its father it will be to me quite a new sensation.—J. S. D."

The above was forwarded to "C.," who replied as follows:—"We really cannot quite comprehend whether 'J. S. D.' seriously expects an answer to his question, or simply wishes to enliven our columns with his wit. Certainly his sense of humour is greater than his appreciation of logic. We repeat that 'as a rule pullets follow their mothers.' We drew no contrast between the influence of mothers and fathers; we never mentioned the latter parents. It is possible for pullets, as good or bad layers, to be like their mothers, or not to be like them. What we assert is, that as a rule they are like them. It strikes us that 'J. S. D.' in trying to convict us of an Hibernicism has been guilty of one himself!—C."

[We insert the above question with "C.'s" answer as an example of the curious way in which readers will occasionally misinterpret words which are perfectly clear in their meaning. While upon the subject we may, however, point out to "J. S. D." that it is of importance in breeding for laying qualities that the father as well as the mother should be bred from a good laying strain. A pullet may follow her female ancestors on the father's side.—EDS.]

#### RECOLLECTIONS OF DORKINGS.

My letter on "The Modern Dorking" has brought me several private inquiries, chiefly as to the colour of this breed before so much uniformity in it was required as is now generally thought necessary. I will therefore, if I may, supplement my former observations with a few recollections which occur to me of the subdivision of the coloured classes, and of the changes in fashion as to colour, that have taken place since I have been actively interested in the breed. Novices are often puzzled with the term "Coloured," and naturally so. It originally signified other than White. "Coloured" Dorkings might be, and certainly at first were, of many colours; then a subdivision was made between the light-coloured birds, which were called Silver-Greys, and the dark-coloured, which were often and still are somewhat incorrectly called "Coloured," and by more precise fanciers "Dark Dorkings."

When first I remember the Birmingham Show (in 1865, I think), the subdivision had not taken place formally, though some people had begun to breed carefully for the silver colour, and birds of it had long been known as "Lord Hill's breed." Mrs. Arbuthnot, writing about 1866, speaks of the subvariety as well established yet ignored by some judges. I think it had special classes in 1868 at Birmingham. From the time that the lighter birds were bred for feather there has always been, in my humble opinion, a

tendency to breed the darker ones also for feather, and to keep them darker than any originally were for the sake of contrast with the Silvers. As I said before, I cannot help admiring the beauty of the rich dark brown hens, but I much regret that that colour should be considered a *sine qua non* for a first-class winner. Why a much greater diversity of colour in the cocks of the dark variety should be tolerated than in the hens I never have been able to discover. Cocks are occasionally found in the prize pen which might do duty as Silver-Greys, and others which are almost black; but to please some great judges the hens must be all of a particular brown, and of late have been required to have black neck hackles. This last is, I venture to think, a particularly unnecessary new point, for some of the prettiest and finest hens in shape, and of rich dark colour too, will have straw markings on the neck hackle.

It may interest some of the inquirers if I briefly describe some of the various Dorkings which I remember in past years at the Birmingham shows and elsewhere. There was little difference in the cocks from those seen now. Some had more and some less dark marking in their hackles; some had brown on their upper wing coverts and back, and some silver or straw colour. From the same cocks pullets of various shades were then bred, and may still be bred, following as they do the colour of their mothers. The hens varied much more in colour than they do now, and it is of them that I will attempt to give a description.

1, There were hens of a shade approaching Silver-Greys, but with much darker and more cloudy neck hackles, and a browner and more indistinct tinge all over the body. I cannot say that I admired them, but they often were very large. I bought one when quite a novice from Mrs. Arkwright's yard, and a magnificent bird she was.

2, The commonest colour, I think, was what I described in my last letter as much lighter than the now fashionable brown with darker edging or spangling to most of the feathers. Such even now sometimes win.

3, A very beautiful type of hen was not uncommon, which I remember hearing called "Dark Silvers." Their general colour was very dark brown with a white shaft to each feather, their tails almost black, but their breast of a pale salmon colour, and their neck hackle silver and black. They were very handsome and striking, but are, I fancy, birds of the past.

4, Really brown hens were common fifteen years ago, but the brown was more rusty and less uniform than the favourite brown of to-day. The first Dorkings I ever possessed, hatched from eggs bought of Mr. Baily of Mount Street, were of this type; they were square, and short-legged, and were not large hens. I subsequently bred pullets from them like their mothers, and also light pullets from light hens (No. 1) by the same cock.

It may be asked, What is the use of recalling what Dorkings have been when we have so beautiful and magnificent a bird as the best Dark Dorking of to-day? My object is to show that a few years ago there was not required so great a uniformity of colour in Dark Dorkings as at present. All fanciers know to their cost how many birds fall short of the colour standard; and what I would advocate is that an otherwise fine bird should never be rejected for too rusty a wing or too light a hackle, or indeed for any colour point which did not clearly show impurity of race. Some will say that a strain which shows much diversity of colour cannot possibly be a pure one. This seems to me by no means self-evident. There are many distinct breeds of horses and other animals which show great variety of colour; and given in a race of fowls several distinctive characteristics of form—such as comb, feet, thickness of body, and roundness of breast—I cannot understand why these should not be sufficient evidence of its genuineness, and some diversity of plumage be permissible. The general form and characteristics of the Dorking are most ancient. Modern breeders may laugh at the supposition that they were imported into England by the Roman invader, because the description of the best fowls given by the Latin naturalists is certainly like them. This, however, I can testify—that on the walls of Pompeii I have seen in mosaic fowls with all their characteristics; where, by-the-by, are also to be seen many of our fancy Ducks—conspicuously the Mandarin and Shell-drake. A race whose form has essentially been preserved through such ages can hardly be one the purity of which should be judged by a tinge of colour.—O. E. CRESSWELL.

P.S.—Since writing the above lines I have read with much interest the letters which have followed my former communication on the "Modern Dorking." Every word written by a fancier of such long standing as Mr. Harrison Weir, and who has, it seems, had such exceptional opportunities of observing the Dorking fowl, is worthy of careful consideration. I am therefore anxious at once to explain myself on one or two points where he has perhaps misapprehended my meaning.

1, Mr. Harrison Weir says, "I think Mr. Cresswell is scarcely within the mark when he writes somewhat slightly of those fanciers who from various causes do not exhibit." I can find no words of mine which contain such a slight, but if any seem to do so I beg most emphatically to disclaim all intention of slighting such fanciers. On the contrary, I have the greatest respect for them, and have repeatedly written to the effect that I believe there are many of the truest and best fanciers who never exhibit; and I added at one time that if poultry shows were not more jealously guarded from malpractices, that I believe most true fanciers would cease to exhibit.

2, Mr. Harrison Weir says that I am "somewhat wrong, though possibly right in the main," about Dorkings having been formerly more judged by weight than now. I base my opinion solely on facts. In former days nearly everybody who wanted a Dorking from my yards inquired the exact weights of birds, now such a question is hardly ever asked; but, what is more to the point, for six or seven years I have never heard of such a thing as Dorkings being put into the scales in judging. In my earlier days of poultry fancying I have several times seen this done.

3, I quite agree with Mr. Weir that large bones are objectionable in a table fowl. I always look for small-boned Dorkings, and have frequently written to the effect that large bones are generally weak. I can, however, see no reason why a large fowl should not have bones small in proportion to its size. I agree, too, with Mr. Weir that a 4-lb. chicken is, as a chicken, better for eating than an 8-lb. one, but the advantage which I find in the modern Dorking is that one can grow the 4-lb. chicken in three months instead of waiting six months for it. It is also convenient at times to have 8-lb. and even larger fowls. Turkeys are troublesome to rear and to accommodate. I find a large and well-fed Dorking fowl if stuffed like a Turkey as nearly as possible its equal on the table. Large Dorkings are so dressed in my house, and I have many times heard visitors observe that they could not tell them from Turkey poult.

In answer to Mr. Smyth's query whether I consider spots on the legs of Dorkings worse than dark feet, I can only say that I consider them both equally blemishes, though spots are more likely to escape the notice of a judge than a general dark tinge.—O. E. C.

[We find by a reference to our former volumes that the Silver-Greys had special classes at Birmingham as early as 1862. These classes, however, were omitted in subsequent years down to 1866, when the Silver-Greys definitely took the position they have since maintained.—EDS.]

## HOMING.

THERE has been much that is interesting written on the powers of the Carrier Pigeon—the length and rapidity of its flights and the modes of training it, as also speculations as to its guide for its homeward course; these latter point to the theory of this bird flying by sight alone. I find that the Rev. E. S. Dixon, in his very interesting work "The Dovecote and Aviary," takes this view. I always hesitate to place my opinion against that of such men of letters as Mr. Dixon, still on this point—the guide of the Carrier on the wing—I beg most respectfully to differ from him. It is pretty well known that I am not an Antwerp Carrier fancier, and do not encourage the Antwerp as a bird that ought to be in the fancy, for several reasons which I shall not discuss at present; but I keep Antwerps for two purposes—first as feeders for my young Pouters, and second for table use. For both these purposes I find them most suitable.

First, then, as to the power of wing possessed by this bird. So far as my personal experience goes I do not think this point is yet fully developed in this country. The plain narrative of what I have experienced may be interesting, and I hope it will not weary your readers. Several years ago when in Manchester I called on the late Mr. W. Millward, a bird dealer, from whom I got all my Belgian Canaries. He had lately arrived from the continent, and brought with him a stock of Antwerp Carriers, which he then found to be most unprofitable. Not having previously seen any birds which I could be sure had been imported I purchased three pairs. The stock consisted of mostly Blues, some Mealies, and some nameless colours; but all were self-coloured, and all showing a cross of the Owl, and having a slight division of the feathers on the breast. Some of them had the breast feathers slightly turned, indicating the frill. They were wild as newly caught Hawks, and strong enough to carry before them a pane of window glass, as indeed one of them did when in my possession. After much care and caution I got them to take to their new home, and found them to be hardy birds. They bred almost the whole year round; indeed, I was never without some few young ones. During the summer season, when there was early light, they took two flights per day—the cocks and unoccupied hens at about 7 A.M., and the hens and unoccupied cocks about 1 P.M. The flock invariably flew southward, and were away for about an hour and a half each time. I have seen them fully ten miles south still holding in that direction. When first noticed on their return they were always at a very great height, but if it were blowing hard (the

weather seems of little consequence to them) they often returned from the northward, having no doubt been carried to the east or west beyond their home.

Three years had passed when a friend came on a visit from Ledbury, Herefordshire. This gentleman saw my Antwerps, and expressed a wish for a pair or two to breed for table use. After he had left for home I caught three pairs, all bred in my Antwerp loft. They were put into a box (not a basket or cage), and addressed to a mutual friend in Manchester, as they could not reach Ledbury in one day from Glasgow. They reached Manchester in the evening, were re-booked for Ledbury next morning, and reached their destination that evening, but till then were not taken out of the box in which I had placed them. Before sending the birds away I had pulled the flight feathers out of the right wing of each bird, and my instructions were, "Keep them confined with such a netting as will let them see the locality till they have each had a nest of young ones, and are sitting upon their second eggs." Those instructions were rigidly adhered to. One night when they were sitting on their second eggs the netting was removed, and the next morning the birds found themselves at liberty. A man was set to watch them. The cocks took sundry flights, and by-and-by relieved their mates who had been occupied in incubation. The hens came out and at once took wing. The date I cannot now give precisely, let us call it the 18th of July. On the morning of the 20th I had a letter from my friend dated the 19th saying, "The birds were let out yesterday morning as you instructed, but two of them have not returned; I am afraid they are lost." While I was in the act of reading my friend's letter, my man who attends to the birds came into my office saying, "I think two of Mr. —'s birds are back." Scarcely believing him I went into the yard, and there certainly were two of the hens I had sent to Ledbury.

Now, I can tell to a mile the distance between Glasgow and Ledbury, Herefordshire, by railway, but I will let your readers measure the distance as the crow flies, and decide whether or not this was a very long flight. Mark, first, that these birds had never been trained; second, that they had never been in anyone's hands till caught by me, when I pulled the flight feathers from one wing of each bird. The birds left their cote at Ledbury about 10 or 11 A.M. on the 18th, and as I did not know what day or week they were to be set at liberty, of course I did not expect them. Indeed, I never expected they would return to Glasgow on the wing. For all I know they may have reached on the evening of the 18th, or during the day of the 19th.

Two months after this I gave to a friend in Paisley a pair of young ones; they had only been two days outside the loft, and had never left it beyond a hundred yards. They were taken away squeakers and confined with a netting in front for three weeks, when let out they were at their birthplace in ten or twelve minutes. It is only seven miles to Paisley, but these birds had never been flown.

Secondly, What is the compass by which the Carrier is enabled to steer his homeward course? "By landmarks," it is commonly said. We know that all Pigeons have a homing propensity to some degree. Purchase a pair of young common birds, confine them a reasonable time, and give them liberty. After trimming their feathers they start on a flight, which is usually composed of one, two, or three circles, and as a rule, unless a strong wind carries them aside, they will alight on the highest attainable point above the place from which they started. Should they be unable to reach their new abode from fear, wind, or other cause, you will at night find them roosting on some window-sill, ledge, or house top nearly above the place from which they had started. Should they be old birds they will either be off trying to find their old home, or from greater power of wing and from more experience having less fear, they will be found at night comfortably roosting in their new home. It is the nature of the Pigeon to "fly to their windows." There are no known landmarks in such cases. The birds no sooner reach the outside of the building than all is strange; still they return to the spot they started from by some very wonderful instinct, whether that spot be in the city or in the country. It is not so, however, with the true Carrier set free in a strange or unknown place. The whole language of his flight and powers is—Home!

"Where the free of soul were nursed  
Is the place that I love best."

I am told that the training of this bird is managed in this wise: He is first taken ten miles away and set at liberty, then twenty miles, and so on in the same direction. In some parts of England three or four towns or villages can be seen from one point, and it would require the powers of reason to distinguish one from the other. I do not suppose that the Carrier is endowed with reason. When the Carrier is let loose, say a few miles from home, he immediately rises in a spiral flight, the object of which is not to survey the strange locality, but to reach a certain altitude. When this has been attained he shoots off in the direction of home. It may be a few points to the right or to the left, but the rule is he holds on in the homeward direction. I have seen some birds go off in the contrary direction till nearly out of sight, when they will suddenly turn and retrace their way as if drawn by some unseen magnet. Now, if the bird does not take time to make himself acquainted with the first point, how can it be a landmark for time to come? The same thing applies to all the other points to which he is taken. For the sake of argument let us allow that landmarks are indispensable. What of the landmarks when the bird is carried in the course of his flight by strong winds

many miles to the right or left, or to such a distance that even the eye of the Carrier cannot reach? Were these birds to fly above our highways or railways we could understand the assertion that landmarks were indispensable; but when their path is, as it were, in the sea, ever varying, never twice the same, I do not think landmarks are of any consequence.

I have noticed Carriers returning from the northward when they should have come from the south. I account for this by strong winds having carried them beyond their home to the right or left, and I think this fact alone sets aside the question of landmarks. The Rev. Mr. Dixon, to whom I have alluded, seems to think that high grounds intervening are apt to make the birds lose their way. Now my birds that came from Herefordshire must have surmounted many very high hills—namely, the Westmoreland hills, unless, indeed, they were carried by high winds, east or west, nearer to the coast—still they reached the place of their birth safe and sound. How can this be accounted for? Although I hold the old writers on ornithology in the highest respect, still I can see that too many of them are mere copyists. One touches a possible chord, and many others follow by striking the same strings. There is not that independence of thought which this theme deserves.

I am told that on some parts of the continent keepers of the Carrier fly their birds during the night. This is worth inquiring into. If it is a fact—which I believe it to be—then the idea of landmarks is out of the question. But it will be asked, How do I account for the wonderful performances of the Carrier without the aid of landmarks? My reply is, that I believe it to be all embraced in the four lines of the old poet—

"I hear a voice you cannot hear,  
Which says I must not stay;  
I see a hand you cannot see,  
Which beckons me away."

As to training, I believe the whole use of it amounts to giving the bird confidence and strength of wing, and I believe he will come from any other direction with the same precision as the one to which he has been trained.

This subject seems to me to be one of vast importance both scientifically and commercially, and to deserve the attention not only of all Pigeon fanciers but also of scientific men. I invite all your readers to give their experience and ideas upon it. Surely it possesses an interest far above any other point connected with our pastime.—JAMES HUIE.

## OUR LETTER BOX.

**Profitable Ducks (B. E.).**—Unless you have means of separating them you cannot keep more than one breed of Ducks pure. Aylesburys, Rouens, and Pekins are the three most suitable sorts. If you intend to rear ducklings for the early spring markets, the first-named will be best. Rouens are also good table birds, but do not come in so early. Pekins are perhaps the best layers of all, and although hardly so weighty on the average as the others, are easily reared, and make good table birds. If you mean to sell eggs for hatching, the Pekins will probably pay best, as they are a comparatively new sort and are fashionable at present. As regards egg-production much depends upon the laying qualities of the strain, so you should be careful to obtain information on this point, if possible, before purchasing your stock.

**Fowls Trespassing (F. Wood).**—It would be illegal to shoot them. Your neighbour is bound to keep his fowls from trespassing; send him a written notice that if he do not restrain them you will sue him in the County Court for the amount of damage they do. Galvanised-iron netting, 2 feet high, without any bar at the top, placed above the wall would prevent the intrusion.

## FIBRELESS COMPOSTS.

**A**MATEURS, possessors of a greenhouse and a few plants, occasionally ask me what kind of "dirt" gardeners employ to grow their plants in. There is a very apparent feeling amongst amateurs who have not had a long experience in growing plants that gardeners are far ahead of them in this matter of "dirt," and that much of the trouble and want of success they experience would be overcome could they be quite sure about the proper medium to grow their plants in. Amongst gardeners who are hindered from obtaining any fibrous turf for potting, we occasionally hear a little "grumble" about the want of interest employers take in their garden and the trouble they have to get a suitable compost. It is certainly annoying to be debarred a few loads of turf annually, when, perhaps, there are hundreds of acres to pick from, and to be expected to grow plants as well as your neighbours who have their stocks of turf always in good condition. However, the fact remains, that many proprietors will not have grass land cut up, and flowers and plants are looked for just the same as if a fertile meadow were always at the gardener's command. There is no use grumbling about these untoward circumstances, the wiser plan is to make the most of the material that can be obtained. In the hope, then, of helping gardeners living in the midst of grass land which they dare not touch, and amateur cultivators who cannot obtain turf except at a dear rate, I will relate my management of soils for potting.

When I first settled here and inquired about turf for plants, I was referred to an out-of-the-way plot of grass which had been covered with trees, but it was so sandy and the turf so poor as to be useless. I also tried some from the sides of roads, but with such unsatisfactory results that I at last had recourse to some heaps of soil which had in various corners been allowed to accumulate, but this was only employed for the choicer plants. For bedding plants almost any soil is used, with the addition of a third part of spent Mushroom-bed material, and the plants do well for the short time they are in this compost. For winter-flowering plants, which are grown in the kitchen garden through the summer months, I sometimes employ the garden soil, adding a similar proportion of manure. For such plants as Chrysanthemums, Carnations, Primulas, Cinerarias, Fuchsias, and Pelargoniums, I have always been able to obtain fresh loamy soil. At present I am employing a loam heap which has been formed from the roots of Twitch Grass gathered off some of the fields, and Potato shaws. This makes the best base for a compost of any I have yet tried; it is quite as good a material as many "turfs," and

much better than anything in that way which I have yet had here. There is no fibre in it with the exception of Nettle roots, which would be much better absent; but after a few years' experience with soils devoid of fibre, we learn from failures how to make the most of any material.

A compost for pot plants should be rich in plant food, and at the same time of a texture that will stand the necessary daily waterings without becoming soured. Turfy loam answers the last of these requirements perfectly, and in a greater or less degree the former also. In a compost of common soil openness of texture is required which the roots of grasses naturally supply in turf, and, therefore, lasting properties must at the same time be secured. Good loams are richer in plant food than common garden soil, and that has also to be considered in mixing the compost. All fertile soils have the constituents necessary to plant life present in varying quantity, with the exception of the elements derived from the atmosphere and water. Lime, potash, phosphoric acid, and nitrogen may be, one or other or all, present in insufficient proportions for the well-being of the plants, and the cultivator in compounding his heap must see that there is a sufficient amount of each added. In horse and cow manure we find the most ready means of at once procuring these manurial agents, and also a medium of openness in the soil, which lasts for the great majority of plants as long as it is required. Some turfy loam is capable of supporting plants for a long time without any addition of manure. Ordinary garden soil will not do so. Only stunted growth will be made in such a soil in comparison to what it ought to be, and a soured condition will very soon be apparent at the roots of the plants. An addition of at least one-third of manure is as little as most plants will flourish in when potted in fibreless soils. If the manure is used in proper condition and prepared aright, the above proportion of manure serves as plant food and also opens the soil. Horse manure I always use in the form of Mushroom-bed refuse. It is not of much lasting value, as the manurial constituents are to a great extent exhausted in the production of Mushrooms, but for plants which are to remain only a month or two in pots, and which are required to grow quickly, such as bedding plants, it answers well.

Some flowering plants, such as Fuchsias, succeed in a mixture of the above and cow dung; but as a rule I prefer cow dung alone as a manure for most plants in pots. The last-named manure must be employed in a fresh state to at once obtain the most beneficial effects from it. I obtain it in dry weather from the park, where it dries quickly without losing much of its manurial qualities, and is in a fit condition to rub down into small flaky particles. The soil and the manure must be evenly incorporated throughout; for many plants, after having been roughly mixed with a shovel, it is passed through the hand, all lumps of soil being rubbed down at the same time. I have discontinued the use of leaf soil entirely, as I believe either of the manures I recommend is better. Bone-meal and prepared half-inch bones are employed, also soot. Chemical manures I have tried in the compost, but I do not think that is the best way to use these; periodical dressings of manure on the surface of the soil are preferable. When fibreless composts are used it is of the first importance to have the pots thoroughly drained. In preference to broken pots I employ sifted cinders. These retain moisture much longer than potsherds, and are, moreover, a more efficient means of drain-

age. It is also of importance to apply just sufficient water to moisten the soil without allowing a quantity to pass through, thereby wasting the food of the plant which the water carries away in solution. It should be understood that the rationale of "watering" consists in supplying the plant with constituents which form a great bulk of its system, and to place within reach of the roots the other constituents necessary to its life and health, and which are held ready in the soil. We cannot in practice keep the soil at all times in just the proper condition; but care in supplying water before dryness is at all advanced, and in just sufficient quantity to merely moisten the soil, with as little waste from drainage as possible, is what should be aimed at.

In connection with this subject of fibreless soils is the intimate one of the application of liquid manure. I do not think it possible to do anything like justice to plants in such soils without supplying liquid manure in far greater quantity than is necessary for plants in fibrous composts. It is a general rule amongst gardeners to give no liquid manure until the plant has been finally potted, and then only when the roots have well filled the pot. I find it necessary to apply stimulants much earlier. I employ water mixed with the manures already mentioned, also with soot, but do not find these as efficient as chemical manures. Nitre is sometimes used alone for inducing rapid growth, as it is rich in potash and nitrogen, but we want flowers in proportion to the growth. Moreover, nitre by itself is expensive. Here is a manure which, while rich in nitrogen, has also the other necessary constituents in proportion. It is from the formula of an eminent agricultural chemist, and will cost about half as much as nitre alone. To make 1 cwt. employ 37 lbs. of superphosphate of lime, 19 lbs. of nitre, 24 lbs. of sulphate of ammonia, and 32 lbs. of plaster of Paris. This contains the following per-centages of fertilising matters—Nitrogen, 6.5; phosphoric acid, 5; potash, 8; and lime, 17 per cent. I am using a simpler and cheaper mixture now, prepared from superphosphate of lime, nitre, and plaster of Paris. As already noted, the best mode of applying these manures is as surface dressings, though I occasionally dissolve a little in the water. It is further to be borne in mind, that there is no use in applying any chemical manure one day and allowing a month or six weeks to pass before another application is made. Plants to be kept in robust health require a dressing from once a week to once in ten days in the warmer months of the year, and about once a fortnight throughout the winter. It will be understood that plants in a growing state, and not in a condition of rest, have been alluded to throughout in these remarks.—R. P. BROTHERSTON.

#### RAISING RHUBARB FROM SEED.

RHUBARB has much to recommend it, as its season of usefulness lasts so long. Coming naturally in April it is capable of furnishing a supply of stalks weekly until the month of October. It can be grown, too, in small gardens in town or country where space and climate preclude the possibility of fruit trees being profitably cultivated. Rhubarb differs much, and a good variety or two will always give most satisfaction. The St. Martin's and the Albert are my favourites. These are of good colour, and bear heavily under the same attention as the more common kinds. Many who grow Rhubarb do not give it a fair chance. Half a dozen good roots in the best part of the garden will produce more useful stems than a score in the customary "odd corner." Allowing the roots to remain for years in the same place has always a degenerating tendency.

Raising a few new plants from seed is a better way of obtaining fresh stock or a new plantation than dividing the old roots. If all growers of old Rhubarb would only be advised to act on this they would reap the advantage in after years. Some who have tried seed may have a word to say against the practice if they have sown it in the open ground and never had a plant from it. I have had the same misfortune, and it induced me to discontinue sowing in the open, and I now raise the young plants under glass. Here they can be obtained early, with great certainty and with little labour or space. In most gardens three dozen new Rhubarb plants would be ample for a supply, or a good addition to the old stock, and the only space required is that needed to hold thirty-six 3-inch pots.

The seed should be sown at once; indeed, I have often found the advantage of sowing much earlier. I sow three or four seeds

in each pot, and place them in any house or frame with an intermediate temperature, where they remain until the young plants are through the soil, and ready for placing in a frame or other structure, to be hardened off prior to planting out. The soil where they are to be planted is trenched to the depth of 18 or 20 inches. If very poor, old vegetable refuse may be worked in near the bottom, and after the whole space has been trenched a quantity of good manure should be dug into the surface.

The seedlings will be found to turn well out of the pots, and they may be planted from 3 feet to 4 feet apart each way. For the first year or two some other crops—such as Spinach, Turnips, or Lettuce—may be grown between the Rhubarb. Preventing the growth of weeds is the only attention needed the first summer. When the leaves die in autumn the crowns are covered to the depth of 2 or 3 inches with manure, and this is allowed to decay, as the young growths push up through it in spring. By the time the roots are sixteen or eighteen months old many of the stems are ready for use, and it is better to remove some of them than allow them to become crowded. The crowns, too, become better ripened in autumn when they are not closely shaded with leaves; and having them thoroughly matured is of considerable importance, especially when the roots are intended to be forced during the winter.

As these notes are intended more for those who grow Rhubarb for summer use than winter forcing I will not enter fully into the latter process now, but may remark that where a large number of forcing roots are wanted annually spring seedlings would keep up a better supply than dividing old roots. Those who may have any difficulty in obtaining pure seed should select one of their own best plants for seed, and so improve their "strain."—PRACTITIONER.

#### ZONAL PELARGONIUMS FOR WINTER.

THERE has been so much written from time to time on the Pelargonium, that perhaps very little more can be said about it to interest your readers. But there still appears to be very few who know the best varieties for winter flowering in a cool greenhouse. As I have given some attention to them for the past few years, perhaps a few remarks might not be out of place. A Pelargonium with from six to ten good trusses of bloom in the dull months of winter is very beautiful, and would be appreciated in any establishment however great the variety of plants grown. They are so much better suited for room decoration in winter than in summer. One good plant in winter will last as long as three in summer. I might name a whole catalogue of good summer-flowering varieties, which would also do well in winter in a house having a temperature about 10° higher than an ordinary greenhouse; but as very few have a house of that description, and those who have one may not require information, I shall name only a few of the best varieties suitable for a cool greenhouse.

*Vesuvius*.—This is well known, but cannot be too well known, for it never fails if properly managed. I noticed two plants of this variety in a cottage window here during the severe weather of the past winter in full bloom. All the care bestowed on them was to remove them from the window at night.

*Charles Smith*.—A beautiful dark crimson variety, and one of the most valuable for winter flowering. I do not know of one to equal it. It may be called a perpetually blooming variety. The trusses are large and well formed. A plant with six to ten good trusses is very beautiful in a vase.

*Rev. F. F. Tenn*.—A very good scarlet variety, and first-rate for winter flowering, bearing very large trusses. I think it would also make a good bedder, but we have only tried it in pots, for which it is most suitable.

*David Thomson*.—A dark crimson variety. The trusses are large, but not so well formed as Charles Smith. They hang rather loosely, the stalks of the single flower being much longer than any of the other varieties. They are very useful for button-hole bouquets if worked-in singly in a half-open state. I made some bouquets this winter of them, with double white Primulas and Violets, and they were much appreciated.

*Colonel Holden*.—An excellent scarlet variety. The trusses are large and well formed. I have measured trusses 12 to 16 inches in circumference in midwinter. It should be in every collection either for winter or summer flowering.

These are five of the best varieties I know for winter flowering. The two I prefer are Charles Smith and David Thomson, which according to my experience are undoubtedly the best. They are all well adapted for planting near the back wall of a vinery. I have them trained up the wall of a late vinery; they flower very freely, and are admired by all who see them. The present is our season of propagating plants for winter flowering. The cuttings are inserted singly into small pots. When rooted they receive their

final shift into sizes suitable for all the purposes for which they are required. I never employ larger pots than 5 or 6 inches in diameter; the plants flower well in these, and are suitable for most decorative purposes.

The soil employed is light fibry loam from an old pasture. It is cut about four weeks before using, pulled to pieces, and placed in a heap till required. The only addition to this is a little leaf soil, a small quantity of charcoal, and a few ground bones. In this compost sturdy plants are obtained that are more likely to give satisfaction than those in a lighter compost. As soon as the weather is warm enough they are placed out of doors on a bed of ashes fully exposed to the sun. They are never allowed to become too dry, and soot water is freely supplied, proving very beneficial, as it is for most plants in pots if used judiciously. I sometimes think that if a little of the extra care given to Roses was bestowed on useful winter-flowering plants, we should have brighter conservatories and flower houses in the dull months than are usually seen.—J. McK., *Leadenham*.

#### THE BARNET NURSERIES.

MESSRS. CUTBUSH & SONS' Highgate Nurseries are well known to most horticulturists, but many are unaware that a very large number of their plants are propagated and grown at the High Barnet nursery, indeed the chief bulk of their stock is raised there. What are termed hardwooded plants constitute the chief feature under glass; and in the open air Conifers, Roses, and Hollies, with numerous ornamental shrubs and trees, are grown in large numbers. During a recent visit I took a few notes in each department, which may possibly be of some use to readers

Fig. 66.—*Erica primuloides*.

intending to purchase and requiring a small selection of good plants.

**EPACRISES.**—These popular and useful plants are largely represented, though at the time of my visit the chief portion of the stock had been cleared out; and the extent of the trade in such plants may be estimated from the fact that more than thirty thousand are annually propagated of all the best varieties in commerce. Being sturdily grown, and gradually shifted as they progress until they are in 48-size pots, they constitute extremely useful plants for decorative purposes, though of course many are disposed of at a smaller size. The chief point to insure the satisfactory flowering of Epacrises—as, indeed, with most other plants—is to have the wood thoroughly ripened, and without that is effected little success can be expected. The following varieties would form a collection suitable for most gardens, but where an extensive collection is grown many other beautiful varieties might be added. *White*.—*Alba odorata*, fragrant, fine white flowers. *Hyacinthiflora candidissima*, one of the best whites; flowers of

excellent form. *Impressa alba nova*, very neat. *Impressa candida compacta*, similar but dwarfer in habit. *Lady Panmure*, a beautiful variety. *Mont Blanc*, pure white; a general favourite, and largely grown. *Nivalis*, *nivalis compacta*, and *onosmaeflora*, all good white varieties; with *The Bride*, very delicate and pretty. *Scarlet, Rose, and Crimson*.—*Ardentissima*, medium size flowers, bright scarlet. Brilliant, fine crimson. *Campanulata*, crimson; with the forms *grandiflora rubra* and *maxima*, both red. *Copelandi*, fine scarlet flowers. *Etna*, bright carmine. *Fireball*, excellent crimson. *Fulgens superba*, scarlet. *Hyacinthiflora* and *rosca*, two excellent rose-coloured forms. *Impressa ignea* and *eoccinea*, scarlet. *Lucifer*, very bright scarlet. *Model*, beautiful pink, large lobes; and *Vesuvius*, bright glowing crimson. *Bicolors*.—*Butterfly*, white tube, rosy limb, late; a good variety. *Coruscans*, rose, tips of lobes white. *Eclipse*, an extremely useful variety, bright red tipped with white. *Grandiflora rubra*, white and carmine. *Lady Alice Peel*, delicate rose tubes, white limb. *Miniata splendens*, bright crimson tube, white lobes; rather loose habit, but an excellent variety. *Racemosa*, rose-red tube, pink lobes. *Salmonea*, salmon tube, carmine lobes; and *Sunset*, pale orange tube with blush-tinted lobes.

**ERICAS.**—Heaths are grown even more extensively than the Epacrises, the annual stock propagated exceeding sixty thousand. Numerous varieties are represented, but a few, such as *E. hyemalis*, *E. gracilis*, *E. melanthera*, and *E. Willmoreana*, are grown in large batches to supply the demand that exists for these popular and comparatively easily grown forms. The season was not one at which a selection could be made, as there were few in flower, but the vigorous health of the whole stock was remarkable. Many hundred feet length of frames are devoted to plants in all stages of growth, and all appear to be equally thriving. In the houses are some excellently trained specimens of the choicer varieties, comprising those of slower growth, which require considerably more care in their culture. What they require they certainly have, for the majority of the specimens could not be surpassed in health and neatness. Of the few species in flower one particularly attracted my attention—namely, *Erica primuloides*, the *E. dilecta* or *delecta* of gardens, a spray of which is represented in fig. 66. It is remarkable for its dwarf compact habit, and the small but extremely pretty flowers being borne four or five together at the points of the branches. The flowers are white with a faint pink tinge and a dark circle near the centre, which contrasts markedly with the delicacy of the other portion of the corolla. It was introduced to this country from the Cape early in the present century, but is still comparatively rare.

In the general collections of hardwooded and New Holland plants many pretty rarities are included, besides a good stock of the best kinds. *Eriostemons* receive some attention, especially *E. scabrum*, which is of dwarfer growth than several of the other species, and also flowers very freely. *Genetyllises*, *Darwinias*, *Dracophyllums*, *Boronias*, and many more genera are represented by the most useful forms known. A charming little myrtaceous shrub, *Hypocalymma robustum*, that is very seldom seen, was flowering very freely and well deserves to be more generally grown, for when a plant about 2 feet high and the same in diameter is bearing a profusion of its small bright rose-coloured flowers it is very attractive. The accompanying sketch (fig. 67), of a spray shows the character of the flowers and the mode in which they are borne on the shoots, but the latter are frequently more branched. The flower has five small rounded petals and numerous stamens, the leaves being narrow, and when crushed they emit an odour resembling Lemons. The plant succeeds

Fig. 67.—*Hypocalymma robustum*.

admirably in a compost of loam, peat, and sand if care is paid to draining the pit thoroughly, an ordinary greenhouse temperature being suitable for it. Seeds were originally obtained by Messrs. Lucombe, Pince, and Co. of Exeter, from the Swan River Territory, and the plants raised were first distributed about forty years ago.

Camellias, Azaleas, and many other plants are also extensively grown under glass, while the stock of Hollies is remarkable, comprising over fifty thousand specimens of various sizes and many varieties, respecting which a few notes will be contributed at a future time.—L.

### NEWCASTLE SPRING SHOW.

THE fifth spring Show of the Newcastle-upon-Tyne Incorporated Horticultural and Botanical Society, which has been established fifty-six years, was held on the 6th and 7th inst. in the Town Hall and Corn Exchange, which as usual were effectively decorated for the occasion. It was an immense improvement on any of the previous spring exhibitions of the Society; the Azaleas especially were represented in greater numbers and of much superior merit than heretofore. The plants that secured the premier honours shown by Mr. Yule, gardener to H. Pease, Esq., Pierremont, Darlington, elicited the highest encomiums from experienced critics. Such old-fashioned spring flowers as *Dielytra spectabilis*, Wallflowers, and *Spiræas* were shown in more than ordinary excellence, and visitors from London considered the Exhibition superior to those that have been recently held in the metropolis.

In Class A, open to all, for four specimen plants in bloom, no less than eleven lots were staged, many of which were of great excellence. Mr. Yule was an easy first with a good plant of *Genetyllis tulipifera* over 4 feet through, splendidly flowered and coloured. *Dendrobium nobile*, 5 feet through, crowded with flowers; a good *Aphelaxis macrantha*, and *Clerodendron Balfourianum* constituted his stand. Mr. John Crozier, gardener to J. W. W. Wilson, Esq., Shotley Hall Gardens, being second with a superior plant of *Erica Wilsoni* in excellent bloom; *Dendrobium nobile* and *Azalea Criterion* were also very good. Mr. James Noble, gardener to Theo. Fry, Esq., Woodburn Gardens, Darlington, was third, his noteworthy plants being *Tetratheca hirsuta*, which was grand, and *Erica barbata* major, very good. In the other stands many good specimens were staged, notably those from Mr. John Thompson, nurseryman, Newcastle, which comprised a magnificent plant of the rare *Cymbidium eburneum* bearing twenty-two open flowers. This plant elicited from all sources much admiration, and a special prize was awarded for it. Mr. Neil Black, gardener to Misses Pease, South End, Darlington, exhibited an excellent plant of *Rhododendron Countess of Haddington*; and Mr. Battersby sent a fine *Anthurium Schertzerianum* with very large spathes.

For four specimens of *Azalea indica* there were ten competitors against two last year; the plants extended in one row the entire length of the hall, and had a most charming effect. The training was much superior to former occasions. Mr. Yule was first with four good plants of *Roi d'Holland*, Mrs. Wm. Bull, Iveryana, and Perfection. They were very open in size and symmetrical in form. Mr. Methven, gardener to J. Lange, Esq., Heathfield House, was an excellent second. His plants were taller than the first, but very profusely flowered. Mr. Neil Black was third with very fine pyramid specimens, and the flowers were excellently coloured. Many excellent Azaleas were shown, some of which were not in bloom, which might have been remedied had they been placed in a higher temperature. In the corresponding class for two Azaleas thirteen collections were staged, all of excellent merit, Mr. Yule being first and Mr. W. L. Thompson second. For three *Rhododendrons* (dissimilar) Mr. Yule was also first, followed by Mr. Noble with fine plants of *R. Gibsoni*, *R. Countess of Haddington*, and *R. Nuttalli*. In the corresponding class Mr. Yule was also first, followed by Mr. Anderson.

For six plants of *Dielytra spectabilis* Messrs. John Thompson and Sons were first. Seven collections were staged; being just placed above the following plants they had a very effective appearance. The foliage was of good colour as well as the flowers. It is seldom they are seen done so well. In the B division Mr. Yule and Mr. Blanchard, gardener to Mrs. Burrell, Low Condercum, Benwell, were first and second. *Spiræas* in both A and B classes were excellent, some of them exceeding 3 feet in diameter; the foliage good and the flower spikes numerous, Mr. Noble being first in both classes. The *Cinerarias* were fine in both classes. In the A class eight collections of six were staged, which were much admired. Some of the plants had heads of flowers 2 feet across. They were placed in a high position at one end of the room, from where all visitors had easy access to inspect them. In the A division class Mr. G. Pattison, St. Ann's Hill Nursery, Carlisle, was first. In the B division class Mr. Yule was first among six competitors. Primulas were very numerous, Mr. T. Lawson being first with six very fine specimens in 6-inch pots. Mr. Woods, gardener to H. N. Middleton, Esq., Fenham Hall, was first in the corresponding class of division B. The display of spring flowers was still further augmented by the handsome *Cyclamens*. Mr. Yule continued his extraordinary success here by taking first in both classes with plants,

appearing not more than two years old, superbly flowered. Mr. Pattison was second with plants that had been very fine, but were slightly past their best.

Lily of the Valley was shown in greater numbers than in any previous spring Show. In the A division class for six pots five competitors entered, Mr. Yule being again first, Messrs. Thompson & Son second, and Mr. Lawrenson third, all showing admirably, both foliage and flowers being good. In the corresponding B division class Mr. Noble was the chief exhibitor. Hardy perennials, Scillas, and Hepaticas were also well shown. In all the Society's Shows table plants form a strong feature, no less than twelve collections of six being staged. Mr. Whiting, gardener at Shot Tower, being first, followed by Messrs. W. Lawrenson and Yule.

Auriculas were not shown so numerous nor so well as last year, which is accounted for by the Show being a week earlier and by the past severe winter. Handsome prizes were offered by the Society for these plants. For twelve Auriculas (dissimilar) Mr. Thos. E. Hay, Killingworth Colliery, was first with Glory, four pips; Mrs. Sturrock and Pizarro, nine; Ruby, nine; Blackbird and Lancashire Hero, six; Charles Perry, ten. Mr. Edward Adams, Swallow, second, and H. Sanderson, Whalton, third. For six dissimilar varieties (Alpines excluded) Mr. Hay was also first, and Mr. Adams second. For four dissimilar varieties (Alpines excluded) Mr. Jos. Watson, nurseryman, Fenham Park, was first. For single specimens of green-edged, grey-edged, and white-edged varieties Messrs. H. Sanderson, E. Adams, and Thos. E. Hay were respectively first. For one Auricula, premier plant in Show, Mr. Thos. E. Hay was first with Lancashire Hero containing six pips. Polyanthuses were also inferior to those of last year. For six gold-laced varieties Mr. Atkinson, florist, Winlaton, was first with Formosa, Beatrice, Diadem, and some seedlings finely laeod; Mr. Wm. Henderson, gardener to Col. Cowan, Blaydon Burn, was second, his stand containing a flower named Queen of the Tyne. For six Polyanthuses, other than gold-laced, Mr. Atkinson was first.

Hyacinths formed one of the grand features of this Show. For the Society's prize of £5 six collections of twenty-four were staged, Mr. Jos. Watson being placed first with handsome specimens bearing massive spikes and healthy foliage. Messrs. John Thompson and Son were second with good specimens, but in some instances a little past their best. Messrs. Nairn & Son, Pilgrim Street, were third with moderately fine examples. In the corresponding class for twelve Hyacinths Mr. Jos. Watson was again first with plants equal to his twenty-four; Mr. Nairn was a good second. In the corresponding B class Mr. J. Brown, gardener to Mrs. Joicey, Whinney House, Gateshead, was first; and for six Mr. T. Liddell, Low Fell, obtained a similar position. Double and single Tulips both in divisions A and B were very good, Mr. Jos. Watson winning both prizes in the former class, while Messrs. J. Woods and J. Storrie were successful in the latter. The display of Polyanthus Narcissi was magnificent. In each class forty-five pots were shown, and each pot contained ten to twelve spikes of flowers.

*Cut Flowers and Table Decorations.*—For these there is strong competition at all the Society's shows, and the present one was no exception. For twelve Camellia blooms Mr. W. L. Thompson, gardener to Captain Bell, Wolsington, was first. Mr. Yule was first for twelve *Rhododendron* trusses. For twelve Azalea blooms eleven collections were staged. Mr. J. Short, gardener to A. Pease, Esq., Hummersknott, Darlington, was first with fine flowers. Roses were not numerous, Mr. Pattinson being the chief exhibitor, and was placed first with twelve *Maréchal Niels*. The first prize of £2 10s. for an epergne brought out in the A division class twelve competitors, and ten each in the B and C division classes. They were arranged on the central table of the Town Hall, which were flanked on each side by the numerous bouquets. In the A division Mr. Whiting was first. His stand was very effective. The top tier consisted of *Salvias*, *Anthurium Schertzerianum*, and *Deutzias*. The base consisted chiefly of *Eucharis*, Azaleas, and *Amaryllis*, the whole being draped from the top tier with *Fuchsia* sprays. Although heavy it was admirably arranged. Mr. Thompson, gardener to Lindsay Wood, Esq., South Hill, Durham, was second. He had his usual March stand. The top consisted of *Oncidium sphacelatum*, *Spiræas*, and four large spikes of *Oncidium excavatum*. This hung down to the bottom of his stand, and gave it somewhat a heavy appearance. Twelve bridal bouquets were shown, Mr. R. Pattinson being first. His arrangement was very effective, consisting of white Camellias, Roses, *Spiræa*, *Phalænopsis amabilis*, and *Odontoglossum Bluntii*, which were evenly arranged with *Adiantum gracillimum*. Amongst greenhouse plants *Genistas* were shown well, also *Acacias*, and the display of *Richardia æthiopica* was certainly not by any means the least effective part of the Show. Several neat designs in the hand-painted unbreakable flower pots were shown by Mr. W. H. Hilton, London Road, Liverpool, not for competition. Mr. John McIntyre also submitted an excellent dish of Strawberries, apparently of President and Garibaldi.

Mr. Gillespie, the Secretary, and his numerous assistants were successful in carrying out all the arrangements satisfactorily to both exhibitors and visitors. The Committee were indefatigable in rendering every service necessary, and we were informed that the receipts on the first day were nearly £40 more than last year. The object of the Society being incorporated was to provide against contingencies of failure, as each one of the Council now becomes responsible for any financial deficit that may be incurred. Only

10s. subscribers are termed members, and that have any voice in the management of the Show. Of 5s. members there are nearly two thousand, while the 10s. members have not at any time exceeded two hundred. The former are now called associates only. Amongst the general body of these members there is a feeling of estrangement at their power being nullified. Whether the Committee have done wisely in instituting the new order of things no one can tell. There is not the slightest doubt they acted so for the best, and their reason for not admitting the 5s. subscribers as members was that the incorporation would have cost six times more than it has, and that the general body of members have never taken part in the annual meetings.

#### MARIE VAN HOUTTE ROSE—HARDY FLOWERS.

"*Humanum est errare.*" This must be my apology to all your readers who feel aggrieved at my omitting Marie Van Houtte from my list of Tea Roses. Shall I ever hear the last of this omission? I have tried to explain how this came about; but as another letter on the subject appears in the Journal this week allow me to apologise once more, and to say that I hold Marie Van Houtte to be one of the finest, if not the finest Tea Rose in cultivation.

Shall we ever have done with this terrible winter? Snow fell early in October, and now we are in the middle of April, and dire winter, or worse than winter I hold such east winds as these, still reigns. I went down to Tooting one day this week to see Mr. Peter Barr's Narcissi and Daffodils. A howling wind blew the dust in my eyes, and did its best to prevent my getting there at all; but I struggled on, and at last reached the nursery, to find few plants in bloom. The Hellebores were over, and the Daffodils only just beginning to bloom. Here and there you might find a choice one, but most were the ordinary single Trumpet Daffodils, and these seemed to shiver in the wind. I had not the heart to go further and investigate matters at Mr. Parker's, so my journey in the cruel north-eastern was a bootless one.

Talking, however, of hardy flowers, may I ask if any of your readers have noticed how these are now neglected in Kensington Gardens? Whole beds of herbaceous plants are being done away with. At Queen's Gate there used to be long beds full of these plants; now these have been dug up, the ground has been levelled, and grass is sown. Where there are a few plants hens are allowed to hunt and scratch for worms, and the whole herbaceous grounds seem to me to be most neglected. All that has been done this winter has been to put some leaf soil on the surface of the beds; the plants are not divided, but left to multiply and grow just as they like. It seems to me a great mistake on the part of the authorities to do nothing to promote the cultivation of herbaceous plants, and I hope you will allow the Journal—which is, I know, read and valued by the Curator of the Gardens—to draw his attention to this matter. Might not also labels, with the names of the plants clearly written as at Kew, be added? This is done for all the trees and Conifers; why not, then, for the Paeonies, Irises, McGaseas, &c.?—WYLD SAVAGE.

#### SHEFFIELD FLORAL AND HORTICULTURAL SOCIETY.

A SPRING Exhibition was held by this Society in the Cutlers' Hall, Sheffield, on the 4th and 5th inst., and such a fine display of Azaleas and early spring flowers has seldom been witnessed in Sheffield. Among the principal features of the Show were groups of plants (foliage and flowering) arranged for effect. The first prize in this class was taken by Mr. James Keeling, gardener to D. Ward, Esq., with a very tastefully arranged group, containing well-flowered examples of *Dendrobium Wardianum*, *D. crassinode*, and *D. nobile*, Camellias, Azaleas, *Imantophyllums*, *Anthurium Schertzerianum*, and Cinerarias, healthy plants of Crotons, Palms, and Ferns. Mr. James Udale, gardener to H. E. Watson, Esq., was second with an excellent group containing very fine Azaleas, a handsome seedling *Rhododendron* with large pure white flowers, and good Hyacinths and Tulips. Mr. J. Walker, gardener to B. P. Broomhead, Esq., was third with a group of smaller plants, which were, however, very fresh and bright, especially noticeable being a number of well-grown plants of *Lachenalia tricolor*. In the class for six varieties of *Azalea indica* Mr. J. Udale was first with remarkably well-flowered plants of excellent varieties. For a single specimen *Azalea* the same exhibitor was again first with a grand plant of *A. Stella*. For three Orchids Mr. Keeling was first with *Cœlogyne cristata*, *Cattleya Trianae*, and *Odontoglossum Alexandræ*; Mr. Udale being second with *Dendrobium Schröderii*, *D. densiflorum*, and *D. crystallinum*. For a single specimen Orchid Mr. Keeling was first with a very finely grown *Dendrobium Wardianum*.

British Ferns were shown in very satisfactory condition considering the severe winter they have just passed through. In the class provided for a group of these Mr. John Eadon was first with fine *Scolopendriums*, representing upwards of twenty varieties. British Filmy Ferns were well shown by Messrs. H. Davy, J. G. Newsham, and

J. Eadon. Cinerarias, Mignonette, and Hyacinths were chiefly exhibited by Mr. J. Walker, who was placed first in the classes provided for each. The Cinerarias and Mignonette were greatly admired. Narcissi were shown by Messrs. T. B. Hague and J. Walker, who were first and second respectively.

Messrs. Fisher, Son, & Sibray of the Handsworth Nurseries exhibited a splendid bank of plants not for competition, especially noticeable amongst which were fine groups of *Cyclamen persicum giganteum*, *Lily of the Valley*, *Azalea indica* and *A. amœna* in large numbers. *Rhododendrons* of the Princess Alexandra and Taylori type, which are finely grown at Handsworth, were represented by well-flowered specimens. Healthy specimens of *Cymbidium eburneum*, *Oncidium concolor*, *Odontoglossum cirrhosum*, *O. Alexandræ*, and several *Dendrobiums* were also staged. Mr. Crossland of the Richmond Nurseries exhibited a group containing a large number of finely grown Hyacinths, good specimen plants of *Arancaria excelsa*, and a number of good Azaleas. A Fern case was shown by Mr. H. Davy of Pitsmoor, containing a collection of varieties of Filmy Ferns in luxuriant health.

Cut flowers formed a fine display; the chief prizetakers were Messrs. J. Udale and Keeling, and Walker. Mr. Keeling was also first for a buttonhole bouquet, which consisted of a single bloom of *Dendrobium crassinode*, with a small spray of *Euphorbia splendens* and *Hotæia japonica* behind and above it, with a single small Fern frond for the background—a very tasteful arrangement. A grand pyramidal-trained plant of *Gloire de Dijon* Rose about 5 feet high, and 4 feet through at the base, loaded with expanded blooms, was shown by Mr. Udale, and deservedly obtained the first prize.

The Show was opened to the public at 1 P.M. on Monday by the Society's President, H. E. Watson, Esq., in a very appropriate speech. He was supported by the Vice-President, W. Chesterman, Esq., Master Cutler, and several patrons. The general arrangements of the exhibits were under the direction of the Curator, Mr. B. Simonite, who succeeded in giving general satisfaction.—W. K. W.

#### WOLFF'S GARDEN PENCILS.

THE utility of these pencils was established after much discussion in our columns, and the manufacturers now ask us to direct the attention of our readers to a mode of making the pencils with a new swivel attachment, which admits of a string being tied to the pencil for the purpose of hanging it in the greenhouse or potting shed, and so preventing its being mislaid, and of securing it to the dress of the owner so as to be always ready at hand. The usefulness of this simple arrangement is at once apparent on reference to the accompanying figure.

Fig. 68.

#### PLANTING POTATOES.

THIS very important crop ought to be planted now the ground is dry. It is essential that the soil be in good condition for Potatoes and the sets well prepared. Both points will have been gained by those who have delayed planting, and a start will be made equal to that of last season, which contributed materially to the production of heavy crops.

The owners of small gardens who do not attempt to grow many Potatoes should confine themselves to the growth of early kinds only, as this will admit of the ground being cleared in time for a profitable successional crop. *Mona's Pride*, *Rivers'*, *Veitch's*, and *Myatt's Ashleaf* are all suitable, and on a hot sandy soil *American Rose* or an improved form of it. *Extra Early Vermont* will crop heavily and be of good quality. The rows of the four former may be placed 2 feet apart, and the sets 9 inches apart in the rows. On strong soils the rows should be 30 inches apart, and the Americans should also receive this space. If it is intended to crop between the rows, and which is advisable where other space cannot well be spared for Brussels Sprouts, Kales, Autumn Cauliflowers, and Broccoli, the rows of the Ashleafs ought to be disposed 3 feet apart, and the stronger growers 42 inches.

The ground cannot well be too loose for Potatoes, and for this reason the old plan of drawing drills is still commendable, especially if the ground be dry. Where the ground is undug the Potatoes may be planted as the digging advances, using a line and clearing the drills with the spade. This practice does away with the necessity of trampling on the soil, which in many instances has to be guarded against. The sets are sometimes dropped into holes made with a blunt

dibble and covered with the help of a hoe. This is the most expeditious method, but is not recommended to be adopted except on light soils. Shallow planting should be practised on heavy soils, a depth of 6 inches being suitable for medium and light soils. In all instances all side shoots should be rubbed or picked out, carefully preserving the strong central shoot at planting time, as much better results are thus obtained. It is not advisable to cut kidney Potatoes of the Ashleaf type, but the rounds may be cut into sets according to the size of the tuber.

If solid manure is used it should be dug-in well below the sets, and any artificial manure should be sprinkled in the rows at planting time. The latter should be used very sparingly, or too much top growth and disappointingly light crops will result. Snowflake and Schoolmaster are good main-crop varieties, and where there is plenty of space at command Magnum Bonum should be largely grown. Scotch Champion is very suitable for planting in fields.

These notes are written with the object of aiding amateur cultivators to produce a satisfactory supply of Potatoes for the table, and they may also possibly be useful to some young gardeners who have hitherto spent most of their time in the "houses," but are now finding out, as all young men do, that Potato culture is an important element in gardening; and some of them, too, need a reminder that the new fancy varieties that are necessarily costly are not nearly so much prized by a gentleman when they are placed on his table, as they are by the cultivator when he places them in the ground. These varieties are suitable for exhibition, and as such I am not likely to say anything against them, but for everyday table use it is safe to rely on "good old sorts"—at least this is the experience of—A PRIZETAKER.

#### FLOWER SHOW SCHEDULES.

MR. FERGUSON'S letter on page 275 refers to a subject of great importance. It is simply impossible for a judge to please all in any competition, but the difficulty is immensely increased if the schedules are not strictly accurate. In every schedule the exact exhibits should be mentioned, and the number of each sort—viz., If vegetables, best collection of six varieties; nine Potatoes, nine Tomatoes, three Cauliflowers, nine Onions, nine Turnips, one peck and a half of Peas. If twenty collections are staged half would be weeded out at the first glance, and at the second another half, having five left. If the judges cannot otherwise decide, every point should be taken, the points added, and, of course, the larger number stands—No. 1, first; No. 2, second; No. 3, third. Respecting fruits the case is precisely the same. For example: if only one dish of Grapes is mentioned, A shows Hamburgs, while B shows Muscats, causing confusion and dissatisfaction; while if both staged the same variety the test would be easy, and, unless to the confirmed grumbler, the case satisfactory.—R. GILBERT, *Burghley*.

#### ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE Spring Show of the above Society was held in the Waverley Market, Edinburgh, on the 6th and 7th inst. The first day's Show was remarkable for the intense frost of the preceding night, 12° to 16° of frost being quite common in various localities, while at Floors Castle near Kelso as many as 18° were registered. It might have been expected that many exhibitors would be absent, but few were missing, and the Show was good. The Azaleas have never been so large and fine before, and the same may be said of the Orchids, while the hardy spring-flowering plants were very attractive.

Turning to the prize list the first nine classes were devoted to Hyacinths and other Dutch bulbs. These commonly form one of the chief attractions of the Exhibition. This year, however, they were shown in much smaller numbers, and the quality was also below the average. The first prize for twelve Hyacinths was secured by Mr. A. Crombie, Royal Asylum, Morningside; and the first prize for nine by Mr. J. Pearson, gardener to Lady Dundas, Beechwood, Corstorphine. These were the only fine Hyacinths exhibited by gardeners. Messrs. W. Penn, Greenpark, Liberton, and G. Drummond, Edinburgh, were the principal prizetakers in the other classes. Messrs. J. Pearson, Crombie, A. McDonald, Asbfield, and Gordon, gardener to Major Wauchope, Niddrie, exhibited Tulips and Narcissi well, securing the chief prizes. For one specimen Azalea Mr. Paul, Gilmore Place, was first with a grand example of Duc de Nassau; Mr. J. Patterson, Millbank, being second. For four Azaleas the same positions were maintained by the above exhibitors. In the class for six stove or greenhouse plants in flower Mr. Paterson was first with good specimens, Mr. Paul following closely. Fine-foliage plants were below the average, the best six being staged by Mr. S. Graham and the best two by Mr. Paterson.

Passing to the table of plants, 20 feet by 5 feet, we noticed that Mr. Priest, gardener to the Marquis of Lothian, Newbattle Abbey, won the first place with a bright collection of flowering and foliage plants: two fine forms of *Odontoglossum Pescatorei* and a fine *O. Alexandræ*

were particularly noticeable. The second place was gained by Mr. R. M. Reid, South Oswald Road, Edinburgh, with a very effective group; Mr. Paul being third with a group chiefly remarkable for the number of Orchids it contained and its bad arrangement. Several collections of hardy spring-flowering plants were shown, Mr. McLure securing the first prize. Some of the other arrangements were more effective, but in this instance the great variety of plants influenced the decision of the Judges. In the class for two Orchids Mr. Priest was placed first with a fine variety of *Dendrobium fimbriatum* and a healthy *Cypripedium caudatum*. For one Orchid Mr. Paul took first prize with a remarkable specimen of *Odontoglossum Pescatorei* with three branched spikes having respectively over forty, fifty, and sixty flowers each, with several spikes of unopened flowers to follow. The same exhibitor staged the first-prize collection of six exotic Ferns, all large healthy specimens. Passing a number of exhibits of little interest, Mr. Pearson showed some fine examples of Lily of the Valley, Messrs. Paterson and Priest showing pot Roses in good condition. A number of cut Roses were shown, but all of inferior quality.

Fruit was represented by several dishes of good Apples, a Pine Apple, a dish of Strawberries, and eight pairs of bunches of black Grapes; Mr. Anderson, Oxenford Castle, being first with Lady Downe's, and Mr. Kemp, Langlee, Galashiels, a very close second. Only two collections of vegetables were staged; Mr. Potter, Seacliffe, North Berwick, being first with excellent Brussels Sprouts, Seakale, French Beans, Celery, Leeks, and new Ashleaf Potatoes.

The competition amongst nurserymen was very limited. Messrs. Downie & Laird had first prizes for Hyacinths, Rhododendrons, Cyclamens, and Azaleas. Some of the Rhododendrons were enormous specimens, more like young trees than bushes. Messrs. Todd & Co. were successful in the bouquet competition; Messrs. Bryson, Helensburgh, and Sinclair, Prestonkirk, for cut Roses; and Mr. Robertson Munro for hardy flowers.

Several nurserymen contributed groups of plants: Messrs. Downie and Laird, and Methven & Sons having chiefly Rhododendrons; Messrs. Ireland & Thomson a collection of stove and greenhouse plants. Drummond Bros., Mr. Taylor, Hermitage, Leith, and Mr. G. Sinclair, Prestonkirk, East Lothian, and the Lawson Seed and Nursery Company, Edinburgh, also contributed interesting collections of plants. Mr. Potts, Fettes Mount, Lasswade, staged a collection of 260 kinds of Saxifrages, a lemon-tinted-leaved seedling named *S. Fetestonia aurea* receiving a first-class certificate. Messrs. W. Thomson and Sons exhibited some remarkably tasteful bouquets, crosses, and wreaths. Stuart & Co. had on exhibition two of their new patent granolithic vases designed for West Prince's Street Gardens. The material is exactly like sandstone. First-class certificates were awarded to the following plants—*Rhododendron Thomsoni*, large sweet-scented white variety from Messrs. Ireland & Thomson; *Soldanella minima alba* from Mr. Robertson Munro, and the above-named Saxifrage. Four Vanda trusses from Mr. McIntyre, The Glen, Peebles, were highly commended; as was also a basket of flowers consisting of double and single Pelargoniums and blue Cinerarias from Mr. McMillan, Broadmeadows, Berwick.

#### ROSE AMATEURS.

I AM acquainted with numerous Rose growers and Rose showers. May I through your columns be permitted to ask the Committee of the National Rose Society to deal promptly with what is likely to become an important question? We wish to know what constitutes an amateur, what he may and may not do. I do not desire to enter into particulars, but I think I am justified in saying that if the Committee do not clear away doubts on this point a serious difficulty will arise at their Rose shows. I know many others who, like myself, feel keenly about it, and who, although not likely to protest, still think that they are not having fair play. If the matter is taken in hand by the Society everyone will be satisfied; but if it is neglected the evil will grow, and what can be remedied now with little trouble and no ill-feeling may hereafter endanger the welfare and even the existence of the Society. A word from you, sir, would go a long way. If you can, please say it in behalf of—A GENUINE AMATEUR.

[We consider "an amateur," in the sense referred to by our correspondent, is a grower of Roses, but not for sale.—ED.]

#### DOUBLE ZINNIAS.

THERE are few more gorgeous flowers than these that can be so readily raised from seed and easily grown in pots for the adornment of the conservatory. They are represented in various colours, some being of great richness, and the symmetrical forms of the flowers are highly imposing. It is not always that plants which bear blooms equal to those represented in fig. 69, can be raised from an ordinary packet of seed, but I have seen many in no respect inferior the product of seed that has been saved from well-grown plants and selected flowers. Seeing how readily and profitably seed of popular half-hardy annuals can be raised, it is somewhat surprising that some of our enterprising florists and seedsmen who have light glass structures at their disposal do not

make an effort to raise seed from selected plants, and so establish equal or superior strains to those of the foreign growers, and keep more of English money in this country. British florists have surpassed the continental growers in raising superior strains of such plants as Primulas, Cyclamens, Calceolarias, and Cinerarias, and why cannot they do the same with Stocks, Asters, Zinnias, &c.,

that are indispensable for gardens in summer? There appears to be a wide field for trade enterprise and cultural skill open in this direction in England. In a small way seeds of such plants as those referred to have been raised "at home," and the results have been so good as to encourage the practice on a larger scale. But to return to the Zinnias. Flowers equal to those referred to

Fig. 69.—DOUBLE ZINNIAS.

have been raised from English-grown seed, the plants having been grown in pots and the seed ripened under glass.

Only gentle heat is requisite for raising Zinnias from seed, and a cold frame for growing the plants. The present is the time for sowing, and it is of the greatest importance that the plants are not drawn and "coddled" in their early stages. Neither must the roots be much injured during transplanting and potting. To

produce vigorous plants and fine blooms the soil must be rich; that in the lower half of the pots in which the plants are intended to flower should be mixed with fully half its bulk of rich manure, the top portion being lighter, or the young plants may "go off." Zinnias make splendid beds in the flower garden, and for this purpose the singles are, perhaps, as effective as the doubles; but for growing in pots for the conservatory the double are far

pre-eminent, and are certainly deserving of more attention than is at present accorded them.—AN ENGLISHMAN.

### HOLLY HEDGES.

As this is the time of the year when many are thinking of forming hedges it may be of advantage to submit a few practical notes to the readers of our Journal. The best hedge plant is certainly the common green Holly, as it forms an impenetrable and ornamental fence, and when well established acts as a capital break to cold winds. The results of my experience here given have been bought at a great cost, for I have had hundreds of Hollies killed by injudicious or careless planting. The most important matter to be attended to is the purchasing of the Hollies. It is a wise plan to purchase the plants near home, and to see and examine them before buying. The plants which are most suitable for moving have an abundance of fibrous roots; to such the soil adheres well. If the plants have long straggling roots from which the soil easily falls they will very likely be killed by removal. Nurserymen who grow Hollies extensively are careful to transplant them very often, so as to encourage the formation of fibres at the root. On stiff land Hollies cannot be grown satisfactorily for removal unless manure and peat are worked well into the soil. From the above remarks it will be seen that a judicious buyer will have several plants taken up so that he may examine the roots. Before the plants are lifted everything should be prepared so that they can be planted in the required positions without any delay, as it is most injurious to keep Hollies long out of the ground. One of the strongest points in my mode of procedure is to transplant quickly. I have had Hollies lifted in the morning, conveyed ninety miles by rail, and planted before night. There is the great danger of the roots becoming dry, which must be carefully avoided. If by accident the roots do become dry it is a wise plan to dip them into a bucket of water. In planting the soil should be trodden only moderately firm. The best compost to work round the roots to assist the formation of fibres is a mixture of well-decayed stable manure and bog or peat; this worked in liberal quantities into the soil as the work of planting proceeds will keep the roots moist, which is important, especially for young plants. I prefer the months of April or May for planting, but I am guided generally by the weather. We are unable to plant in this locality (Cheshire) at present, as the cutting easterly winds are very severe. I prefer moist weather for transplanting Hollies, no matter what time of the year it be. There are now in this neighbourhood splendid Holly hedges which I planted in a moist July.

In suburban districts many Holly hedges are planted in the front of villa gardens. I have seen hundreds of plants killed by injudicious planting in such positions. Villa gardens of the class I refer to have usually at the front a small stone wall about 3 feet high. The border is made to slope from the level ground to within a few inches of the top of the wall, and the Holly hedge is planted so that it shows well above the wall; it is thus exposed to the wind, and is in danger of becoming dry at the roots. In such a position the wonder is that the plants live at all. Any danger from this cause is easily avoided by allowing the soil to come only within a foot of the top of the wall. The appearance at the outset is not so striking, but in a few seasons the gardener so planting will be gratified by seeing a well-established hedge. Immediately the hedge is planted the soil should be mulched with manure or tan to keep the roots moist. If very dry weather follow the planting the hedge will be benefited by a thorough watering. Gentlemen who have established Holly hedges which are doing badly will find it a good plan to dig well to the roots and work in a liberal quantity of good manure. If care be taken that the roots are not injured the hedge will be found to make a great improvement in a very short time. During the late severe weather Hollies have suffered in many neighbourhoods; it may, therefore, be of use to some to say that when a Holly loses its leaves through frost it is regarded as a good sign, for the plant will in all probability break out into growth when genial weather comes. The mode of procedure mentioned above I have found to be most successful, and the experience which I have pleasure in presenting to the readers of the Journal has been gained over a long period and by many failures and many successes.—VINDEK.

**POTTING CHRYSANTHEMUMS.**—Mr. Brotherston remarked some time since that he gives preference for large pots for the sake of economising labour in watering. Those who wish to grow Chrysanthemums well must not be afraid of such labour, or they had better not attempt the culture. It is not advisable to use larger pots than really are required for the well-being of the plants. Large pots are not required to grow good Chrysanthemums in,

and are rather a disadvantage than otherwise. I may remind Mr. Brotherston that the best blooms I have ever seen produced are not grown from plants in large pots. I do not agree with the advice given in relation to potting. If plants are placed in 5-inch pots at the beginning of April they will grow freely, soon fill their pots with roots, and become root-bound before the beginning or middle of June, then if finally potted into 13-inch pots, they have a shift of 8 inches, which I contend is too large even for a free-growing plant like the Chrysanthemum, especially if the roots have become seriously matted in 5-inch pots.—WM. BARDNEY.

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Major F. Mason in the chair, the following candidates were elected Fellows—viz., Edward H. Allen, Mr. G. C. Armstrong, Mrs. Hope Barton, Lady Cardross, Miss Emma T. D'Eyncourt, the Hon. Hubert Dormer, The Hon. Mrs. Hubert Dormer, John Henderson, Mr. Francis Hornby, Mrs. Little, Miss Lock, Miss Mallard, Henry H. Moore, Frederick A. Mullett, Wilfred Nicholson, the Hon. Mrs. T. Preston, George Russell, Joseph Seel, Mrs. Louisa P. Stevenson, Frank C. Stileman, Mrs. Frederick Streatfield, Frank Whitlock, Major-Gen. F. L. Whitmore, Samuel J. Wilde, Major Woodhouse, and Mr. W. Parkinson Wright.

— AFTER a term of unusually COLD WEATHER—keen easterly winds blowing almost a hurricane night and day for weeks, arresting the growth of vegetation and jeopardising newly planted shrubs—a favourable change occurred in the metropolitan district on Tuesday last, accompanied by a gentle and refreshing shower. From the beginning of March to the 12th inst. only about three-quarters of an inch of rain fell in London; during the corresponding period of last year the amount exceeded 1½ inch. The weather has at least been favourable for drying the land, hundreds of acres of which were not long ago submerged, and for expediting the working of the ground in fields and gardens. In the north of England and Scotland the weather obstacles have been more serious, for during much of the time the ground was dry and in good condition in the south it was deeply covered with snow in the north, which lingers yet in shaded places. Fruit blossoms are late, and on the whole, in the south at least, the late term of cold may possibly in the end prove more beneficial than injurious.

— WE may remind our readers that the Southern Show of the NATIONAL AURICULA SOCIETY will be held in the Royal Horticultural Society's Gardens, South Kensington, on Tuesday next April the 19th, when prizes will be offered in the customary classes, and a satisfactory display is expected. Mr. George Smith of Edmonton will offer three special prizes for the best plant of Polyanthus Smith's Duke of Wellington. An interesting feature of the meeting will be the delivery of a lecture on the Auricula by the Rev. F. D. Horner of Kirkby Malzeard, who has so often enriched our columns with notes on the flower of which he is such a skilled cultivator and ardent patron. We also learn that the Northern Show will be held on April the 26th in the New Town Hall, Manchester, when Auriculas and Polyanthus will be similarly well provided for.

— "D., Deal," writes to us as follows on the CARDIFF ROSE SOCIETY—"The interest that the Rose excites amongst us does not seem to be on the wane, if one may judge amongst other things from the number of new societies which are starting up. The last of these is Cardiff, and one can easily imagine that from its position, its contiguity to Hereford, and the patronage which

it is likely to command, that it ought to be a success. They have made a good start, have obtained the services of that able gardener Mr. A. Pettigrew as their Honorary Secretary, have issued a schedule amounting to £80 in prizes, and have already affiliated themselves with the National Rose Society. The Marquis of Bute has given the Society his patronage, and offers prizes of £5 and £3 for the best boxes of York-and-Lancaster Roses; while the Mayor gives a prize of £2 for the best boxes of Moss Roses, and a Mr. Ware for the best box of the old Cabbage Rose. There are prizes open for general competition as well as for local growers. The Exhibition will be held in the Drill Hall, and with such a start success is well nigh assured."

— MR. W. IGGULDEN sends the following from a letter he has received upon TOMATO CULTURE—"I think the proper cultivation of this delicious fruit-vegetable is far too little known. The taste for Tomatoes seems to be an acquired one, most people having an aversion from them at first. I am exceedingly fond of them both cooked and uncooked, and as a medical man I consider them most wholesome. I grow them largely in pots under glass, and found them infinitely better as regards flavour grown in this way than when in borders even under glass. The most delicious variety I consider is Earley's Defiance, next to this Hathaway's Excelsior. The Trophy makes a capital third, as does Jackson's Favourite—a very large-fruited variety of fine flavour. For a grand crop I have found, so far, no variety to equal the Orange-field Dwarf. From two plants of this in an 11-inch pot I cut seventy-two fruits, some very large."

— IN reference to the PROPOSED INTERNATIONAL FLOWER SHOW AT EDINBURGH, the *Scotsman* states that "a meeting of the Committee of the Caledonian Horticultural Society charged with promoting the International Show which it is proposed to be held in Edinburgh on the 15th and 16th September, 1882, was recently held in the Waverley Market—Professor Balfour in the chair. After discussion it was agreed to appoint a Sub-Committee to draw up a circular, and send it to patrons of horticulture and others interested in it both in the United Kingdom and the Continent, asking their co-operation and support in forwarding the object which the Committee have in view. A considerable amount was subscribed at the meeting as the nucleus of a prize fund; and from present appearances there is every reason to hope that the arrangements for the Show may be carried to a successful issue."

— WE some time ago received from Mr. Miles of Wycombe Abbey a portion of the new PINE APPLE LORD CARRINGTON, a variety which had been certificated by the Fruit Committee of the Royal Horticultural Society a year ago. That which Mr. Miles sent us was even richer and more highly flavoured than the fruit which was exhibited at South Kensington; and what struck us more especially was the fine aroma which seems to be peculiar to this variety. This is no doubt a fruit of the highest excellence, and our note upon it was made at the time when it was received, although delay has occurred in publishing it.

— THE usefulness and beauty of TROPÆOLUM BALL OF FIRE as a winter-flowering plant in a warm greenhouse or any other structure with a similar temperature, is admirably shown at Nonsuch Park, Cheam, the seat of W. R. G. Farmer, Esq. In one of the plant houses there two specimens of this Tropæolum are trained up each side of the doorway and over a portion of the roof, and at the time of a recent visit they were bearing so many hundreds of flowers that the term a "mass of blooms" seemed the only one applicable. They have been in a similarly fine condition since last October, and Mr. Sillence the gardener has found the supply of flowers obtained from them of inestimable value during the duller months of the year. The plants are growing in good turfy loam, and when they become slightly

exhausted from the continuous flowering the pots were placed in pairs of partially decomposed manure, into which the roots rapidly extended, thus again increasing the vigour of the plants.

— THE following GARDENING APPOINTMENTS are announced—Mr. Thomas Nutting, late gardener to Richard C. Naylor, Esq., Kelmarsh Hall, Northampton, succeeds Mr. G. Eldridge as gardener to Henry Hall, Esq., Manor House, Alton, Hants; Mr. George Jordan, late of Westbrook, Hemel Hempstead, has been appointed gardener to Rev. H. Bermens, Harkstead Rectory, Suffolk; Mr. James Galbraith, late gardener to Sir Wm. Parker, Bart., Melford Hall, Sudbury, becomes gardener to Wm. F. Faviell, Esq., Down Place, near Guildford; Mr. Edwin Tame, late gardener to Col. James, Igtham Court, near Sevenoaks, succeeds the late Mr. Blaides as gardener to J. E. Sanders, Esq., North Sandsfield, Gainsborough; Mr. George Roberts, late of Peter-sham House, near Richmond, becomes gardener to Lord Teynham, Tower House, Shooter's Hill; Mr. J. Taylor, late gardener at Isel Hall, has been appointed gardener to F. J. Reed, Esq., Hassness, Cockermouth, Cumberland; and Mr. William Sowards, late foreman at Castle Hill, Southmolton, succeeds Mr. James Shale as gardener at Creedy Park, Crediton, South Devon.

— AT the ordinary meeting of the METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on the 20th inst. at 7 P.M., the following papers will be read—"On the Frequency and Duration of Rain," by Dr. Wladimir Köppen; "Results of Experiments Made at the Kew Observatory with Bogen's and George's Barometers," by G. M. Whipple, B.Sc., F.R.A.S., F.M.S.; "On a Discussion of Mr. Eaton's Table of the Barometrie Height at London, with Regard to Periodicity," by G. M. Whipple, B.Sc., F.R.A.S., F.M.S.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 12TH.

THE meeting on this occasion was not characterised by any very remarkable features, though the exhibits both in the Council-room and in the conservatory were sufficiently numerous to impart much interest to the gathering. This was still further enhanced by a lecture by the Rev. G. Henslow on Daffodils, and the performance of a selection of music by the band of the Royal Horse Guards.

FRUIT COMMITTEE.—Harry J. Veitch, Esq., in the chair. Mr. T. Bonsall, The Gardens, Campsmead, Doncaster, sent a dish of Improved Keeping Onion. Mr. J. Wallis, Keele Hall Gardens, Newcastle, Staffs., sent three bunches of old Grapes, consisting of Gros Colman, Black Alicante, and Lady Downe's, to which a cultural commendation was awarded. Mr. Buchanan, gardener to Dr. Siemens, Sherwood, Tonbridge Wells, sent a splendid bunch of fruit of Musa Cavendishi weighing 74 lbs., and grown as stated under the influence of the electric light. The Committee were of opinion that it was a very fine specimen of the fruit, and awarded a cultural commendation, while they referred the scientific question to the Scientific Committee. Mr. W. Bowell, gardener to Lady Parker, Stawell House, Richmond, Surrey, exhibited a fine bunch of Loquat, the fruit of which was quite ripe, and pronounced to be the finest flavoured ever exhibited before them.

FLORAL COMMITTEE.—J. McIntosh, Esq., in the chair. Among the exhibits in the Council-room the first to be noticed was a group of new and rare plants from Messrs. James Veitch & Sons of Chelsea. A cultural commendation was awarded for a specimen of *Cattleya Mendelii* superbissima with half a dozen flowers. This is one of the finest varieties in cultivation, the petals being very broad, white, with a faint purple tinge; the lip large, rich crimson, and beautifully fringed. A peculiar Japanese shrub, *Corylopsis spicata*, was also shown with spikes of small yellowish flowers on leafless branches. Mr. H. Cannell, Swanley, contributed several collections of Zonal Pelargonium blooms in excellent condition, extremely bright and well selected. Among the scarlet single varieties especially noticeable were the following:—Col. Seely, Mrs. Newdegate, J. B. Miller, Rigoletto, Tom Bowling, General Grant, Commander in Chief, and Lizzie Brooks. The best pinks were Mrs. Strutt, Louisa, Lady Sheffield, and Olive Carr. The best white was Eureka, recently certificated. Many good double varieties were also shown. Double named Cinerarias were represented by several varieties, among which Kate, full pink; Phoebe, purple, very large, and globular; and Mr. T. Lloyd, deep purple, were especially notable. The hose-in-hose and spotted Mimulus Beauty of Sutton was shown, with flowers of the old Cineraria cruenta and Silver Star Marguerites, the latter

extremely fine and pure white, attracting much attention. Mr. Bull, Chelsea, sent several new plants and *Sarracenias*, two specimens of *S. Drummondii* bearing over a dozen flowers each of very deep colour. *Azalea balsamiflora* was also shown very well flowered. It is an extremely neat variety, the flower being of moderate size but of excellent form, and rosy salmon in colour. It is also very floriferous. A very distinct *Dracaena* named *D. Lindenii* was shown with leaves 3 or 4 inches broad, striped with two shades of green, a dark band in the centre, and lighter on each side.

Mr. B. S. Williams, Upper Holloway, London, sent specimen plants raised from their selected strain of double *Cineraria* seed. They were generally of compact habit; the flower neat in form, full, and brightly coloured, especially the purple and crimson forms. Mr. J. Speed, gardener to the Duke of Devonshire, Chatsworth, was accorded a vote of thanks for flowers of the remarkable *Amherstia nobilis*, for which Chatsworth is noted. The flowers are orange scarlet in colour, three of the petals being tipped with yellow, and they are borne on pedicels 2 or 3 inches long in racemes of a dozen or more. Mr. J. Guyett, gardener to Mrs. J. Perrett, Lynton House, Clapham Common, was accorded a vote of thanks for several heads of *Rhododendron Nuttallii*, each bearing four to six enormous flowers, some exceeding 6 inches in diameter, and possessing an extremely rich fragrance. Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, sent a plant of *Pinguicula valisnerifolia* with violet purple flowers and a whitish eye. Mr. J. Wilkinson, gardener to Viscount Gage, Firs Place, Lewes, was accorded a similar recognition for a group of seedling plants of *Anthurium Schertzerianum*, some with very large spathes and brightly coloured. Mr. W. Carmichael, The Gardens, Nowton Court, Bury St. Edmunds, sent two *Azaleas*—one named *D. T. Fish*, with extremely large pale salmon and crimson-tinted flowers over 4 inches in diameter and of good shape; the other, named Mrs. Wills, was one of the *amœna* section, the flowers being extremely dark crimson. Mr. G. F. Wilson, Weybridge, was accorded a vote of thanks for a collection of seedling Primroses in fine condition.

Mr. G. Smith, New Villa, Hedge Lane, Edmonton, exhibited plants of two seedling Polyanthus, one named Byron and the other Nelson, both good gold-laced varieties, the flowers of fairly good form, and the ground colour dark maroon. Mr. R. Dean, Ealing, exhibited several beautiful hardy Primroses and Polyanthus. Primrose Beatrice, with bright purplish lilac flowers, was especially noticeable. Votes of thanks were also accorded to Sir Charles Strickland, Bart., for a specimen of *Cattleya citrina* growing on a block, and to Col. Clarke for a species of *Hippocastrium* with small bright scarlet flowers.

In the conservatory there was a pleasing and bright display of plants, occupying one side of the central path and forming a fine bank, the arrangement generally being very tasteful. Messrs. Veitch and Sons staged a group of Roses in pots, all in excellent health, and the flowers fine for the season. The specimens in the best condition as regards the number of flowers were Dupuy Jamain, Madame Lacharme, and Beauty of Waltham. Plants of the early-flowering *Magnolia stellata* were also shown, with a basket of the dwarf *Primula pubescens*, and several *Amaryllises*. A gold medal was awarded. Mr. B. S. Williams was awarded a silver-gilt Flora medal for a large and handsome group of Orchids in excellent condition. Especially notable were good specimens of *Odontoglossum vexillarium*, *Dendrobium chrysotoxum*, *D. Dalhousianum*, and *D. nobile*. *Cattleya Trianae nivea*, a pure white variety, was also notable, with many choice and beautiful species. Messrs. Barr & Sugden obtained a silver-gilt Flora medal for a fine group of Daffodils, comprising about sixty varieties, some extremely choice, and all more or less beautiful. A silver Banksian medal was awarded to Mr. J. Aldous, Gloucester Road, for a tasteful group of flowering and fine-foliaged plants, chiefly *Azaleas*, *Spiræas*, *Roses*, *Lilies of the Valley*, *Palms*, and variegated *Maples*. Messrs. H. Lane & Sons, Great Berkhamstead, exhibited a group of *Rhododendrons* in pots, the central plant being a specimen of the variety *Snowflake*, bearing about three dozen trusses of white flowers; several other good varieties were also shown, and a large group of *Roses* was also contributed, for which a gold medal was awarded. A group of *Dielytras* and *Cinerarias*, with several *Primulas*, was sent from the Society's gardens, and Messrs. Smith and Larke, Kensington, sent several wreaths and crosses of white flowers tastefully arranged.

First-class certificates were awarded for the following plants:—

*Gymnogramma schizophylla* (Veitch).—This elegant little Fern, of which we gave an engraving last week, was again deservedly honoured with a certificate. The specimen possessed the chief characters of the plant well developed, both the proliferousness and the branching of the fronds being shown.

*Adiantum monochlamys* (Veitch).—An elegant Japanese species, somewhat suggestive of *A. assimile*. The fronds are bipinnate, with triangular light green pinnules, each having the outer margin distinctly notched. The habit of the plant is graceful.

*Dioscorea retusa* (Veitch).—This plant has now been in cultivation several years, and has been previously awarded a botanical certificate. It is, however, very graceful, and merited the recognition it has now received. It is of climbing habit, with dark green digitate leaves and numerous spikes of small white flowers in dense clusters, which are pendulous from the axils of the leaves. When trained on a trellis of some kind, so that these clusters can be easily seen, the appearance of the plant is very graceful. The plant was figured in this Journal several years ago. See vol. xxxi., page 168.

*Omphalodes Kramerii* (Veitch).—A pretty little Japanese herbaceous plant, with lanceolate leaves 4 to 5 inches long and 1 to 2 broad. The flowers about the size of a large *Myosotis dissitiflora*, bright blue, and borne in racemes 6 inches in height. The specimen had been grown in a frame, but would probably prove hardy in sheltered positions.

*Ivy-leaved Pelargonium Anna Pfitzer* (Cannell).—Many members of the Floral Committee considered this the most interesting plant shown on this occasion. It is a variety with fine double soft pink flowers 2 inches in diameter and of good form. The trusses are large and compact, some bearing nine or ten flowers, and the habit of the plant is dwarf. The leaves are deep green and of the usual Ivy-like form characterising this section.

*Cœlogyne cristata alba* (Bull).—A pure white-flowered variety of *Cœlogyne cristata*, exactly resembling the one for which Mr. Richards of Leeds obtained a certificate at the last Exhibition of the Royal Botanic Society.

*Pinguicula Bakeriana*.—A specimen of this very distinct Butterwort was shown by Messrs. F. Sander & Co., St. Albans, who were accorded a first-class certificate for it. It has small, fleshy, spatulate or ovate leaves in a dense rosette, very much like some of the *Sempervivums*. The flowers are borne singly on peduncles 8 or 9 inches high; they are about 1½ inch in diameter, of a rich crimson colour, darker towards the centre, and with a white throat, which relieves the deep colour of the petals. All the characters of the plant shown correspond with those of *Pinguicula caudata* now flowering in the porch of the Orchid house at Kew, where it succeeds under similar cool treatment to that afforded other species of the genus.

*Primrose Amaranth* (Dean).—A pretty variety, with large well-formed flowers, deep crimson in colour shading to maroon, and with a rich yellow eye. The plant was flowering very freely.

SCIENTIFIC COMMITTEE.—*Galls on Artemisia*?—Mr. Pascoe exhibited a specimen from the Sahara, somewhat resembling the woolly gall on *Veronica chamædrys*, of an unknown insect, but the plant resembling an *Artemisia* could not be determined.

*Canker on Apple Wood*.—Dr. Masters exhibited a specimen to elicit opinion as to the cause. Dr. Hogg attributed it to frost, observing that water would often settle in the axils, form ice there, which then destroyed the tissues. Trees which were of a more delicate nature, such as Newtown and Ribston Pippins, were more subject to it than others. If the roots of such trees reached a cold damp soil similar results followed, the general previous condition being an unripeness of the wood which leads to canker. *Hyacinth Bulbs attacked by Acari*.—He showed some bulbs with these insects, but they were regarded only as a consequence and not the cause of the decaying state of the bulb. *Viridescence of Primula sinensis*.—He exhibited an umbel of which every flower consisted of a ball-like mass of green leaves. *Sarracenia*.—He showed a blossom in which the exterior surface of the foliaceous stigma produced folds and tubular outgrowths not infrequent in Cabbage leaves. *Potato Disease*.—He exhibited leaves from a correspondent taken from plants in frames; five kinds were attacked, and the earliest sorts took it last.

*Nolina georgiana* was exhibited by Mr. Elwes, it being the first occasion of its flowering in England. It is a native of the coast of Carolina. Its blossoms resemble a Squill, but with the foliage of *Bomarea*. Cattle are said to eat it greedily, hence it is called Buffalo Grass. He also exhibited a Tulip from the Elbury Mountains near to T. violacea, but with the colour of T. saxatilis, which moreover possesses broad shiny foliage. He also showed *Tulipa iliensis*, allied to T. sylvestris. Mr. Elwes remarked upon the rapid changes which Tulips undergo under cultivation, not merely in the glabrous or downy filaments but in the shape of the stigmas, &c. He commented on the growth of *Arisæma speciosa*, an Aroid from Sikkim. The spadix bears a long filiform appendage. This latter is always found wrapped up in the terminal part of the leaf long before the spathe unfolds.

*Boronia megastigma*.—Messrs. Veitch exhibited plants bearing pale as well as dark-coloured blossoms on the same stem. A discussion arose as to the possible interpretation of this—that it might be the first step towards self-fertilisation.

Dr. Siemens exhibited a bunch of green Bananas from a tree which was only 18 inches high in March, 1880, but had had the benefit of the electric light for the first three months at night. During the summer it had only sunlight, but for the last six or eight weeks the electric light had again been employed at night. The benefit appeared to be due to starting the growth last spring.

Col. Clarke exhibited specimens of Cowslip, Oxlip, and *Primula acaulis*, which seems often to simulate both the others. Mr. G. Bunyard exhibited specimens of the *Mezereon* with tumour-like growths on the stems and roots. They were too old to pronounce as to the cause, whether it be hypertrophy of the bark or of a fungoid character. He also sent flowers of a *Polyanthus* with the petals separate. Rev. G. Henslow exhibited some resin-like inspissated sap from the Alder, from Lord Lytton's Park, Knebworth.

LECTURE.—The Rev. G. Henslow took the Narcissus as the subject for his lecture, there being a fine display from Messrs. Barr & Sugden's nurseries. He drew attention to the characters of the family *Amaryllidaceæ*, to which the genus belongs, and pointed out the sole distinction between it and the Lily family (*Liliaceæ*), that in the latter the ovary is free from the tube of the perianth, whereas the latter organ was adherent to it in *Amaryllids*—it thus becomes

inferior, or apparently below the perianth. Taking *Narcissus* as a typical genus he described the five sections into which it is divided. 1, *Ajax*, which includes the Daffodil, with its very long corona, and having the filaments of the stamens adherent very low down; 2, *Ganymedes*, with a drooping *Cyclamen*-like habit, and reflexed limb, as *N. triandrus*; 3, *Hermione* or *Polyanthus Narcissus*, with its slender tube and shallow corona, such as *N. Tazetta*, which is naturalised at St. Michael's Mount, and flowers three months earlier than near London; 4, *Queltia*, with a sub-cylindrical tube and short corona; and lastly the true forms of *Narcissus*, as *N. poeticus*, with the tube widening at the mouth, &c. Several other genera, such as *Pan-*

*tium* and *Ismene*, have coronas, but it is not characteristic of the majority of genera in the order. It has been regarded as an abortive whorl of stamens, inasmuch as it sometimes bore supernumerary anthers.

The family *Amaryllidaceæ* is represented by three genera in Great Britain—the Daffodil, the Snowflake, and Snowdrop, the two last having free segments to the perianth and no corona. In comparing *Amaryllids* with the *Lily* family, the Daffodil with coherent lobes may be paralleled with the *Hyacinth* and *Lily of the Valley*, while the Snowdrop and *Amaryllis*, with free lobes, would compare with the *Tulip* and *Star of Bethlehem*. With regard to the distribution of

Fig. 70.—*ERIOBOTRYA JAPONICA* (THE LOQUAT). See page 298.

the *Amaryllids*, *Narcissus* and *Galanthus* (Snowdrop) represented the family in temperate regions. *Pancreatum* first appeared on the borders of the Mediterranean, *Crinums* and *Pancreatiums* abounded in the West and East Indies, *Hippeastrums* were numerous in Brazil and South America; but the greatest number is at the Cape of Good Hope, such as *Hæmanthus*, *Crinum*, *Clivia*, *Brunsvigia*, and *Amaryllis*. With regard to the properties of the family, acrid, narcotic, poisonous principles occur. The Daffodil is narcotic in small doses, while large doses of the petals are poisonous. *Pancreatum maritimum* has the same properties as, and is substituted for, the Squill, a bulbous plant of the *Lily* family, which also occurs in the Mediterranean region. *Hæmanthus toxicarius* of South Africa is intensely poisonous. The

Kaffirs use the juice with the venom of snakes and the milky juice of *Euphorbia* for an arrow poison. Similarly, *Crinum zeylanicum* is violently poisonous. On the other hand an arrowroot or starch is extracted from the bulbs of *Alströmeria pallida*, &c., in Chili. One of the most useful of this family is *Agave americana* of Mexico, miscalled the American Aloe. The true Aloes are African plants, much resembling the above, but belonging to the *Lily* family. The American Aloe blossoms once within a hundred years and then dies, producing a flowering stem sometimes 40 feet high, and bearing three thousand blossoms. In Mexico the stem is tapped, the juice collected and allowed to ferment. It then forms a kind of beer called pulque. A very intoxicating spirit is also made from it by distillation. The juice

contains both oil and an alkali, and so forms a substitute for soap with water. It is thus used in Portugal and Spain, as the American Aloe is much grown in South Europe. The flower stem cut vertically makes a good razor strop, in consequence of the silicious particles it contains; while the fibre of the leaves is of considerable value, and is called Pita. Lastly, cattle are fed on the bruised leaves in dry seasons.

### THE LOQUAT.

FRUIT CULTURE both under glass and in the open air receives much attention in England, yet though the varieties of the fruits already established in gardens are being continually increased, few efforts are made in a systematic manner to extend the number of distinct kinds in use. With the exception of Bananas there have been scarcely any general additions to the ordinary fruits from under glass. The edible Passifloras, such as *P. edulis* and *P. quadrangularis*, have also been tried, but by no means extensively, and the same may be said of the *Eugenia Ugni*, which some years ago was brought prominently into notice, but is now comparatively neglected. Many other famed tropical and sub-tropical fruits might be mentioned which are grown in a few establishments more as curiosities than for any practical purpose, and yet there is little doubt that if more attention were paid to them satisfactory results would be obtained, and many a dish of novel and richly flavoured fruits could be added to the dessert, which are either now quite unrepresented or are obtained from importers, such fruits being usually deficient in their most gratifying characteristics. It is only in the largest establishments where such could be grown at all extensively, but there are few gardens in which some could not be tried with little additional trouble and expense. Difficulties invariably attend the early efforts in cultivating foreign plants of any kind, and perhaps in most instances it is less easy to obtain fruit-bearing exotics in satisfactory condition than it is to grow good specimens of plants that are chiefly noted for their ornamental foliage or beautiful flowers, yet it has been more than once proved by energetic and skilful gardeners that such difficulties can be overcome. There are few if any such fruits which could be profitably grown for sale or as a main crop in gardens in this climate, nor is it likely that they will ever be extensively tried with that object, but as an occasional and welcome novelty for the table they might receive more attention than is at present accorded them.

One of these neglected fruits is the Loquat, the *Eriobotrya japonica* of botanists, which, though known in this country for nearly one hundred years, generally admired for its handsome foliage and famed for its fruit, has been rarely grown except as an ornamental tree or shrub in the open air or in glass structures. Partly owing to this, and partly to the season at which the flowers are produced, fruit has been rarely ripened even under glass, and still more rarely out of doors, so that much interest is attached to any instance in which it has been matured under either of those conditions. The most recent recorded occurrence of the fruiting was that noted a week or two ago on page 255 of this Journal, where it is stated that a specimen of the Loquat was then bearing fruit in the garden of the late Sir Henry Watson Parker at Stawell House, Richmond, Surrey, now the residence of Lady Parker. By the liberality of the owner the public were permitted to inspect this specimen, and many persons availed themselves of the privilege. The tree is 9 or 10 feet high, in a pot about 14 inches in diameter, and it bore a dozen bunches of eight or ten fruits each at the ends of the branches, where the long rich dark green leaves were clustered as they usually are in specimens of moderate size. The tree had been previously in a stove, where it flowered in late autumn last year; and having received careful attention a crop of fruits was set which gradually advanced to about the size of Apricots, and became fully ripe towards the end of March, then assuming a fine orange tint. They were not only larger than many we have seen, but possessed a much richer flavour than any we have previously tasted. As they each contained a single seed, it is probable the variety is that referred to by Fortune as the one most highly valued by the natives of China and Japan. There is a great difference in the quality of the varieties, some being comparatively worthless; and wherever this or any other foreign fruit is intended to be grown, a point of great importance which is frequently overlooked is the selection of the variety. The great defect in most of the fruits of the Loquat which are occasionally seen in the metropolitan markets is their insipidity or even unpleasant flavour, due probably to their having been gathered in an unripened condition; but were all as fine as those grown at Stawell House there would soon be a demand for them in this country. The engraving on page 297, prepared from a specimen kindly sent by Lady Parker, represents one of the clusters of fruit the full size, and conveys a very good idea of the fruit which, as we have remarked, is a pale orange tint

on the surface and slightly downy. It is extremely juicy, and possesses a sweet, rich, sub-acid, vinous flavour quite distinct from any other fruit.

A brief review of the history of the Loquat may not be devoid of interest to some readers now the tree is under consideration. The species is a native of Japan and China, where it was found by Kämpfer towards the close of the seventeenth century, and described by him under the name of *Mespilus japonica*. Many years subsequently the plant was more fully described by Thunberg under the same name, and a drawing was also published with that author's "*Flora Japonica*." In 1784 it first appeared in Europe, living specimens being imported by the French and transferred to the National Garden at Paris, and two or three years later Sir Joseph Banks obtained some plants from Canton and consigned them to the Royal Gardens, Kew, thus introducing the plant to English cultivators. The stock appears to have been gradually increased by propagation and probably by subsequent importations, and early in the present century it was represented in many gardens. Since then it has become generally distributed, and is now by no means rare, especially in the southern counties, where it thrives against walls in the open air, and is rarely injured except by very severe frosts, such as we have experienced during the past winter. The first record we have of a tree producing fruits in England occurs in the third volume of the Horticultural Society's Transactions, published in 1822. A letter is there printed from Lord Bagot of Blythfield, Staffordshire, which was read before the Society in 1819, and recounts the fruiting of a tree in one of his lordship's houses. Fruits were produced during several years, generally of very fine quality and extremely numerous, as many as twenty-one having been borne on one branch. The method adopted was to place the trees out of doors during the summer, removing them to a warm tan bed in September. The flowers generally expanded in December, and the fruit was ripe by April. But on one exceptional occasion the flowers appeared in early summer. From that time until the present there have been few records of the production of fruit under glass. Loudon mentions one or two instances, and others have been noticed at wide intervals, but it is still an event of considerable interest. There are scarcely any well authenticated instances of trees maturing fruit out of doors in England, though in the south of France, Malta, and neighbouring regions it is produced in great freedom.

At the recent meeting of the Royal Horticultural Society Mr. Howell, the gardener at Stawell House, exhibited fruits from the Loquat referred to here, and was awarded a cultural commendation for them, the Committee being of opinion that they were the best flavoured ever submitted to their inspection.

### HARDY FRUIT GARDEN.

THE cold wintery weather which has been prevalent now for some weeks has considerably retarded the flowering of the Apricot and the advance of other fruit trees in a corresponding degree; indeed the blooming is likely to be a month later than it usually is, which augurs well for the fruit crop. Frosts may even in May yet occur to destroy the blossom and tender fruit, but it rarely happens that frosts after the middle of April are sufficiently severe to injure the fruit crop, particularly if a slight protection be afforded. Apricots in flower should have efficient protection; coverings that can be readily fixed and withdrawn are the most suitable, as the trees cannot be too fully exposed to light. Peach, Nectarine, and Plum trees, as they come into bloom should also be protected. The flowers of the Pear and Cherry should have similar attention. All necessary grafting should now be completed as quickly as possible, but owing to the unusual coldness of the weather fruit trees and stocks are only now beginning to grow freely. Fork over the soil of fruit tree borders to the depth of about 2 inches, as a loose surface admits of the freer admission of rain and air.

### FRUIT HOUSES.

*Peaches and Nectarines.*—In the earliest forced house the fruits should be finally thinned, retaining one fruit to every square foot of

trellis covered with foliage. If it be desired to accelerate the ripening of the fruit the night temperature may be maintained at 65° to 70°, 75° to 80° in the daytime, and 85° to 90° with sun heat, closing at 80° with plenty of moisture in the house. It is much better, however, for the future well-being of the trees to finish off the fruit in a temperature of 60° to 65° at night and 70° to 75° by day, allowing an advance to 80° or 85° from sun heat, ventilating above 70°, and closing at 75°, and if the temperature then rises to 80° or 85° it will be an advantage. Peaches and Nectarines may be grown to a large size by maintaining during the last swelling a moist atmosphere and high temperature, but the fruit is not so good in colour and flavour as that ripened in a drier atmosphere and with better ventilation. If the trees are at all weakly give a good soaking with weak liquid manure at 75°, and mulch the inside border with short manure 2 to 3 inches thick. Syringe twice a day, and damp the house well before nightfall. When indications of ripening appear discontinue syringing the trees, but damp the house several times a day according to the weather. This will hardly be necessary as yet, except with such extremely early kinds as Early Beatrice, and where those are in the same house with Royal George, which is four to six weeks later, the syringing must still be continued. Train the shoots as necessary, and have the fruit as much exposed to the sun and air as possible. Trees in the house started at the new year must be syringed twice a day, watered whenever necessary at the roots, and have the shoots tied in as they grow. Maintain an equable temperature of about 60° at night or a few degrees less on cold nights, 60° to 65° by day in dull weather, and 70° to 75° from sun heat, ventilating above 65°. In the house started early in February disbudding has been completed, and the shoots will need to be heeled or tied down carefully at the base. The trees started early in March will require attention in disbudding, which should be done gradually, leaving a growth at the base of the current year's bearing wood to form next season's bearing wood, retaining a growth on a level with or above the fruit, pinching out its point at the third leaf unless required for extension. Trees extending should have growths left on last season's wood at 15 to 18 inches distance, and the shoots that are to form the branches should not be closer than 12 to 15 inches. Remove the smallest and badly placed fruit gradually. In late houses the fruits have set and the inside border must not lack moisture, damping the house in the early part of fine days and again in the afternoon and syringing twice a day. Fire heat will be necessary to maintain 45° by artificial means at night, or 5° less on cold nights, and 50° by day, above which ventilate freely. Fumigate upon the first attack of aphides, also for thrips, on two consecutive evenings, being careful to have the foliage dry. If syringing does not subdue red spider apply an insecticide.

*Figs.*—The fruit of the earliest forced trees in pots are now commencing to ripen, therefore cease syringing the trees. Increase the ventilation, as a circulation of rather dry warm air is essential to perfecting this fruit. Surface roots are of primary importance in the cultivation of fruit trees, especially of the Fig; and if a mulching of short manure was given at commencing forcing and it has been kept moist it will be full of active roots, and in the case of early-started trees will now require a liberal supply of water in a tepid state; or if the trees will bear it without becoming too luxuriant, weak liquid manure may be applied. Proceed with tying-in the shoots, leaving plenty of space in the ties for the swelling of the shoots.

*Nepenthes.*—These also may be repotted, or rather moved into larger pots if they require it; but there must not be any attempt at removing the old soil from the roots, for they are very tender, and have, even when healthy, the appearance of being dead. Employ the same compost as named below for *Sarracenias*, and drain the pots extra well, as they require very copious supplies of water during growth. Syringe overhead daily in the afternoon, and maintain a good moisture by damping available surfaces frequently. A temperature of 70° to 75° should be accorded them by artificial means, 10° to 15° more from sun heat.

*Sarracenias.*—These may now be potted, removing all the old soil as far as can be done without injuring the roots, using fibrous peat and chopped sphagnum in equal parts, with a sixth of potsherds and

a sprinkling of sand, and keep them liberally supplied with water at the roots. All the species do well in a winter temperature of 45° to 50°, and 10° or 15° more in summer as the weather may determine. They should be near the glass, and not be syringed much. The pots or pans may be half filled with drainage, keeping the shelves constantly moist.

*Greenhouses.*—Spring potting of *Aphellexis*, *Adenandras*, *Acrophyllum venosum*, *Chorozemas*, *Dracophyllum gracile*, *Eriostemons*, *Tremandras*, *Statice*, and other plants of a similar character should be completed as soon as possible, as the drier condition of the atmosphere later on makes it rather difficult to manage newly potted plants. Any hardwooded plants of which it is wished to retard the flowering should be removed to a house with a north aspect. *Plumbago capensis* is very useful for summer and autumn flowering, and should be grown in a light position. Plants in 6 to 8-inch pots are most serviceable, and any plants now in 6 or 7-inch pots should be cut well back, and when they have started transfer them to pots an inch larger, sandy loam with a little leaf soil suiting them well. Cuttings of double *Petunias* inserted now strike freely in gentle heat, and grown on will afford acceptable plants for decorative purposes later on. Plants in small pots should be shifted into a larger size, keeping cool and near the glass, stopping the shoots to induce a well-branched habit. *Fuchsias* should be kept in a temperature of 50° at night, this applying to both last year's struck plants and older required for early bloom. *Pelargoniums*, from the increased leaf growth and the pots being filled with roots, will need a little more water. Fumigate upon the first appearance of aphides. The late *Cinerarias* should be moved to a north house. They like a still moist atmosphere, as also do *Calceolarias*, both of which should be assisted with weak liquid manure.

*Conservatory.*—Remove all plants past their best and supply fresh, of which there will be a great number to make an effective display. Slight shade will be necessary for *Azaleas*, *Spiræas*, *Cytisuses*, and other plants in flower in the middle of the day, or they will continue but a short time. A strict look-out should be kept for insects, which now increase rapidly; and if allowed to get ahead are difficult to deal with in this structure, as the means of destruction by fumigation and washing are more objectionable in this than other plant structures. *Lily of the Valley* should after flowering be returned to a light airy house and be well supplied with liquid manure, keeping them there until the weather is mild, when they may be placed outdoors, but not before June, in an open situation, and they will ripen early and be again available for early forcing. *Deutzias* should be removed to a house where there is a moderately high temperature, as that of a vinery being forced, where they will be encouraged to produce fresh growth. Cut out all the present flowering wood down to the collar of the plant, which will induce them to produce strong shoots that when in flower have a better appearance than the formal plants resulting from the partial cutting-back system.

## NOTES ON VILLA AND SUBURBAN GARDENING.

### HOTBEDS.

*Cucumbers and Melons.*—From this time little difficulty will be experienced in forcing these. Telegraph is the most popular variety of Cucumber, and about five seeds may be sown in a well-drained 6-inch pot. The seedlings when in rough leaf to be carefully separated and potted singly into 4-inch pots, burying as much of the stems as possible, which will then emit roots. Employ light loamy soil previously warmed. The seed may be sown singly in 4-inch pots, allowing room for top-dressing as the plants become stronger. In either case and at all times the bottom heat should not be below 65° nor exceed 85°. To induce sturdiness keep the plants near the glass, pinching back the running growth to the second joint, and when fresh growth commences is the time to plant. A few days previous to planting, a bushel of soil, consisting if possible of two parts of turfy loam to one of well-decayed manure, should have been placed in a heap in the centre of each light. It is advisable if the heat of the bed be dangerously strong to place some turves grass downwards under the soil, and failing these some small drain pipes may be used: either will moderate the heat. Do not plant till the soil is found to be comfortably warm to the hand, as Cucumbers do

not quickly recover if burnt at the roots. Open the soil near the centre and lay in the plant in a sloping direction, slightly burying part of the stem. If placed in an upright position the young growth will snap off when the attempt to train it is made. If the frame is required to be filled quickly have two plants in each hillock, slanting them up and down the bed respectively. If the soil is moist no water will be required for some days, except that sprinkled about the bed on clear days when the frame is closed, and when it is eventually given it should be of the same temperature as the frame. Lightly shade from bright sunshine, ventilating slightly at the back only, and before the sun has gained much power, avoiding cold draughts, and closing early, say about 3 P.M. A little ventilation will be needed during the night should there be much steam in the beds. In the evenings either mats, strips of old carpet or matting, rough litter, or some available protecting material should be thrown over the frames, removing this early in the mornings.

The whole of the foregoing is applicable to Melons, with this difference—the Cucumbers delight in a rough turfy soil, whereas the loam obtained from beneath the turf is often found most suitable for Melons, and should be very firmly rammed about the roots at planting time. The collar of the plants must on no account be buried, as they are liable to damp off, especially if the bottom heat decline considerably. Victory of Bath is an easily grown green-fleshed variety, so also is the Earl of Beaconsfield. Turner's Scarlet Gem and Read's Hybrid are two good scarlet-fleshed varieties.

**Tomatoes.**—Seed should now be sown for the ordinary outdoor crops, and also, if a few are to be fruited in pots, in the forcing house or in a greenhouse. Employ well-drained 6-inch pots and light soil, sowing the seed thinly, covering lightly, and place the pots on a gentle hotbed. The seed will germinate readily; and to keep the seedlings sturdy thin them out if crowded, and have them near the glass. When the second leaves are formed pot the plants either singly in 4-inch pots or in pairs in 6-inch pots, sinking the stems to the seed leaves. Light moderately rich soil previously warmed should be employed, potting carefully to avoid bruising the tender plants. If moist soil be used no water will be required for a few days, but the plants must be kept in heat and shaded from bright sunshine till established. Those without the assistance of a hotbed may cover their seed pots with strips of glass and place them on a greenhouse shelf, shading from bright sunshine. Pot off the seedlings as advised for the preceding. Earley's Defiance and Hathaway's Excelsior are recommended for the outdoor crops, and Vick's Criterion and Conqueror for pots. Nisbet's Victoria, Queen of the Tomatoes, Red and Yellow Cherry, and Royal Cluster are small ornamental-fruited varieties suitable for small conservatories and greenhouses.

**Sowing Seeds of Bedding and other Plants.**—Seeds of *Lophospermum scandens*, *Cobaea scandens*, *Euclyptus globulus*, *Solanums*, *Coleus*; *Capsicums*, including Princess of Wales; *Chamaepeuce*, *Cineraria maritima*, *Perilla nankinensis*, *Abutilons*, *Amaranthus*, *Acacia lophantha*, and *Cannas* must be sown at once and placed in a brisk bottom heat. Light sandy soil is suitable, and the small seeds especially should not be buried deeply. If the *Acacia* and *Canna* seeds are placed in warm water till soft they will germinate quickly, but they should not be transferred to cold soil. A few days later the seeds of *Zea japonica*, *Ricinus*, *Tropæolums*, *Portulaccas*, *Asters*, *Stocks*, *Phloxes*, choice *Godetias*, and *Eschscholtzias*, *Marigolds*, annual *Chrysanthemums*, *Helichrysums*, *Linums*, *Balsams*, and other choice annuals may be sown. A strong heat will not be required for these. Pinch out the points of the bedding *Pelargoniums*, *Calceolarias*, and *Violas*, replanting or repotting when fresh growth commences.

## THE BEE-KEEPER.

### BEEES AND COB-NUT TREE POLLEN.

CAN any of your numerous correspondents tell me why bees do not appear to care for, or do not appear to be aware of the existence of immense quantities of pollen on Cob-nut trees during the latter end of February and nearly the whole of the month of

March? I have about three acres of Cob nuts, part of them just in front of my hives. I have frequently watched them, but scarcely ever saw them on the tail-like pendants of the male flower of the Cob-nut. One would almost think that in Kent artificial pollen would not be required during that period, as an acre of Cobs would almost supply half a bushel of pollen.—J. B. JACKSON.

### AMERICAN BEE JOURNAL.

#### FERTILISATION IN CONFINEMENT.

IN continuation of this subject from page 261, we pass a communication from "M. B.," who tells us he has made the "important discovery," and that in five trials he has had perfect success, because he is so cautious as to postpone an account of his *modus operandi*.

Mr. King Cramer seems to give us some further light, and points a line along which I purpose myself travelling this spring. He says—

"All the experiments that I have read of were made with a box or a barrel with a glass in the end of it. If a queen or a drone flies up and strikes that glass there will be no more mating that day. There is no better way to kill bees than to let them butt against a glass. Not only that, who can tell just the right time to take out the queen for confinement or mating? I at once saw that could not be practicable, and began some experiments, the results of which, together with the *modus operandi* of arriving at it, I purpose, with your consent, to lay before your readers.

"I took a frame of brood, with as many young bees as I could get, and put them in the second storey of a Langstroth hive, with a strong colony of bees in the lower storey in order to get their heat for the occupants of the upper storey, as the nights (about the 1st of September) were getting cold. Now we have a small swarm of bees in the upper storey, with the honey-board between the bees below and those above, and also a honey-board over the upper bees.

"On the second day they were there I gave them a queen-cell. In two days it hatched out. I then gave them ten or fifteen young drones. Now I had the queen, drones, and bees all confined in the upper storey of the hive. The bees were fed and watered every morning.

"The fertilising box is 2 feet high, and fits the hive on the top. It has a muslin cloth tacked over the upper end, and the lid of the hive over that.

"When the queen was three days old I made a small hole 3 inches long and half an inch wide in the honey-board, and took the lid off the cloth, when the young bees and the drones flew around within this box as if they were flying in and out of a hive. Every afternoon the lid was taken off the cloth two hours and then replaced.

"I have two queens in my apiary that mated by this process, and they were the only ones that I tried, as it was too late in the season to experiment further; but I can with safety say that by the end of another season there will be hundreds of queens mated by this process, and fertilising queens in confinement will be proclaimed a success."

We must all hope that his concluding remarks may be realised. Professor Cook writes very suggestively respecting the improvement of bees. He, of course, takes up the line that the struggle for existence has been Nature's method of development by allowing only the survival of the fittest. It is worth the attention of progressive bee-keepers, that in many hands Nature's operation is here being reversed. Several articles touch upon the question of the

#### ADULTERATION OF HONEY WITH GLUCOSE,

of which substance some of the writers speak with impassioned warmth. That adulteration with glucose is a base fraud which all good men must reprobate, needs no enforcement. The case is too strong to require any unscientific denunciation, and it is, therefore, unfortunate that some of these writers speak of glucose as "poisonous stuff," while others detail the "vile nature" of the acids used in its manufacture. This really does not reach the question. Glucose can be made from old rags, old paper (second-hand pawn tickets actually, at least sometimes, being employed thus), and, indeed, any form of cellulose or starch, Indian corn in America usually being the source, and by the action of sulphuric acid can be converted into a sugar which no chemistry, no palate, can distinguish from that taken from the most dainty bunch of Grapes. To refer, then, to its source is useless. It is equal to Grape sugar whatever its origin, and as an article of diet it has its value; but all this still leaves its use as an adulterant most disgraceful, and all should join hands in fearlessly doing our level best to get the right ticket put upon any man (and his wares) who descends to a practice which, if it does not lower him, wrongs all those who are striving to do honestly. Glucose, although chemically like a portion of honey, is altogether wanting in that which makes honey what it is. Its aroma, the delicate distillment from a thousand flowers inimitable and incommunicable alike are not there, and he who gives the one

for the other is as truly criminal as he who tenders knowingly a base coin. Let one of our cousins, Mr. L. H. Scudder, speak for himself.

"Let me caution you not to be too confident that even such prices can be obtained in the near future. Just note, if you please, how rapidly the manufacture of glucose is increasing; factories are being started in all parts of our country, enough are already in operation to consume five millions of bushels of corn annually in the west alone. Now when you take into consideration the fact that they obtain over three gallons per bushel of what they call 'glucose' or 'corn syrup' you will see that over fifteen million gallons annually are thrown upon our markets to be sold and used in various ways. But mark you, not one gallon is sold to the consumer by its proper name. The dear people buy it in their honey, candy, sugar, golden syrup, drips, and in other commodities we know not of.

"If your druggist sells you poison the law compels him to label it, that no harm may come of it. Then why not compel these men to do the same? 'Tis true that they may not sell a mixture so destructive as arsenic or any of the deadly poisons, but just as certainly injurious as any of them. Now my friends, in justice to ourselves and humanity, let us continue our warfare until the people by their representatives in Congress assembled, say to those men that their goods must be properly labelled and sold on their own merits.

"I fancy when that is done there will be a decline in the sulphuric acid and old rag market."

It is interesting to note that the results I detailed in our Journal some time since in reference to American wired-foundation, and once ridiculed on the other side of the Atlantic in a manner a little wanting in taste, are now courteously acknowledged by the inventor, Mr. D. S. Given, to be correct.—FRANK R. CHESHIRE, *Avenue House, Acton.*

#### TRADE CATALOGUES RECEIVED.

J. B. A. Deleuil, Marseilles.—*General Catalogue of Plants.*

**Books (C. L.).**—We do not know of any book precisely suited to your purpose. You should first practise elementary geometry, of which you will find figures and instructions in any good arithmetic as used in schools. "Plane Geometry," published by Crosby Lockwood & Co., London, price 2s., might also be useful to you. It can be ordered through a bookseller. Some of the best and most practical lessons on drawing designs for flower gardens and beds have appeared in several of the back numbers of this Journal. Many young gardeners availed themselves of these, and by assiduous practice rendered themselves competent in this essential part of their vocation; while others merely glanced at the figures, passed them by, and are now unfortunately like yourself—"unable to give a plan of a garden if it is called for." Some young gardeners have no more knowledge of using the compasses than they have of digging a piece of unlevel ground and leaving it level with the least amount of labour. They may be fortunate, and have labourers to do the digging; but they cannot expect them to prepare designs that are so often required by employers.

**Hyacinthus candicans (C. D.).**—The bulbs may be planted at any time when the ground is in good condition. If they are wintered in pots the soil should not be kept dry. We do not know what number you require. If you can state the approximate date on which the article appeared it shall be sent to you.

**Vines Dying (F. C. T.).**—The case is a mysterious one. We presume you are certain that nothing beyond the ingredients named were applied to the rods. If nothing more was applied to them it is certain that mixture would not be the cause of death, as the Vines in the other house show conclusively. Assuming that no mistake has been made in the dressing nor experiments tried, we can only attribute the injury to the action of frost between the haybands. We have known Vines much injured and one killed by the haybands slipping during an intense frost, but the Vines had been started into growth. These are the only suggestions we are able to offer on a circumstance which appears to us of a very extraordinary nature. We are not at all satisfied that frost is the cause of the death of the Vines. Examine them with great care both where the haybands covered them, which parts you say are alive, and in the house where the rods are dead. We sympathise with you, and regret we are not able to give you a more satisfactory reply on the data you have afforded.

**Friendly Letters.**—We have to acknowledge letters from a vast number of correspondents at home and abroad for their congratulations on the termination of a matter that we are surprised to find was of such widespread interest. Many letters are from friends who are unknown to us, and are not the less esteemed on that account. Our thanks are tendered to all those whose letters we are unable to acknowledge in the usual manner through the post.

**Rhubarb Running to Seed (F. J.).**—You had better break off the flower stems as soon as they appear, as they are of no use unless you desire to save some seed, and then one plant will probably afford sufficient for your purpose. When Rhubarb produces many flower stems it is an indication that the plants have either received a check or are getting old, and in the latter case is suggestive that it would be advisable to take off some of the best crowns with roots attached and plant in fresh deeply worked and rich soil. This is best done just as the crowns are swelling in the spring. If your plants are young, liquid manure would be beneficial; and the stalks should not be pulled too closely—that is, some good foliage should be left for forming stronger crowns another year.

**Packing Strawberries (Old Subscriber).**—Shallow boxes should be made on the same principle as referred to for Peaches last week; but for the fruit in question these boxes or trays only need to be 2 inches deep, and several of them can be placed in a larger box made for the purpose, strips of wood between each preventing the fruit being crushed. Each fruit should be wrapped in a partially withered Strawberry leaf or Spinach leaf, and placed closely yet carefully in the tray on a bed of leaves or bran, and a layer of soft leaves on the top. If the packing is carefully done and the fruit not over-ripe it may be sent long distances without being crushed. When packed for sale in the markets the fruit is placed in round chip punnets.

**Allamandas and Stephanotis (J. G.).**—The Allamanda flowers are very fine; the variety is, we think, Hendersoni. The Stephanotis is good, and the fact that the plant flowers continuously over a period of nine months is sufficient evidence of the merits of the variety and your skill as a cultivator.

**Stephanotis Management (H. S. J.).**—If you denude the plant of its side growths you will in all probability deprive yourself of a succession of fine flowers. As room is scarce you may remove those growths that are long-jointed and very luxuriant, retaining all that are shorter jointed, as these may be expected to produce flowers. They can be trained loosely round the wire, and after flowering if the plant is much crowded the superfluous growths may be removed. If you send 3½d. in postage stamps to the publisher, and ask him to send you No. 958 of the Journal, August 7th, 1879, you will find an excellent article on the cultivation of Allamandas. Mr. B. S. Williams, Victoria and Paradise Nurseries, Holloway, publishes some useful books on stove and greenhouse plants, and will send you particulars of them on application.

**Clematis not Succeeding (Bert.).**—We do not quite understand your question. If the house is a lean-to, and the roof is not very short, the plant ought to succeed, if planted in suitable soil and trained near the glass the same as a Vine. What variety of Clematis is it? how long has it been planted? what is the nature and position of the border? and how has the plant been pruned? Information of this nature appears essential to enable us to account for the unsatisfactory condition of your plant.

**Variegated Kale (G. O. S.).**—The leaves sent are attractive, the colours being varied and good, some clear ivory white and the others rich. We have grown superior examples, and have occasionally had varieties equal to yours from a packet of purchased seed that had been saved from selected plants. Your varieties are, however, above the average of those ordinarily produced from purchased seed. The value of a "strain" depends on the percentage of superior forms. If all of yours are equal to the examples sent your strain is a good one.

**Mandevilla suaveolens (P. D.).**—The plant you mention is a native of Buenos Ayres, and received its generic name in honour of John Mandeville, who was minister at that place. It is spelled as given above, and not with the final "ca" as it is erroneously rendered in some catalogues.

**Removing Vine (Donegal).**—If you remove the Vine at all you had better do it in the autumn, say towards the end of September, and then if the weather is bright syringe the foliage several times a day, and shade if needful to keep it fresh; you will then induce fresh root action before winter, which will be a great advantage. From your description of it, however, the Vine appears to be in an enfeebled state, and it is for you to consider whether a strong young cane would not prove more satisfactory. If you decide to remove the Vine first have the station ready, with plenty of loam at hand, mixed with wood ashes and a third of decayed manure if the soil is poor, for covering the roots. These must be kept moist during the process of removal, choosing a dull day for the work, which must be carefully yet expeditiously done.

**Potting Plum and Budding Cherry Trees (Idem).**—If you wish to have fruit as early as possible and small trees in pots, you may pot them now and plunge the pots in ashes outdoors to remain through the summer. The trees would grow larger, but would not be quite so precocious if left in the ground until the autumn. We should prune them as you propose now, pinch the strong shoots in the summer as needed to secure an equalisation of growth, exposing all the foliage to the sun, and pot the trees in the autumn. Cherries are far better budded than grafted. Grafting, if it succeeds, is often followed by gumming. Furthermore, your scions are too advanced. They should have been cut off a month sooner, and kept fresh by being placed in moist soil and a cool position until the stocks commenced growing. We advise you, however, to practise budding, inserting a few buds at different times, and you will soon find out the conditions requisite for success. We cannot state the time, as all depends on the condition of the buds and stocks.

**Various (Idem).**—The pots used for sowing Cucumber and Melon seeds should be washed clean, and be dry when used. One crock and a bit of turf shaken from the soil will suffice for drainage at this season of the year. The plants can then be turned out of the pots without the roots sustaining any injury. If you have moss over the drainage we should not remove it when repotting the plants. The manure may be used fresh from the stable for lining frames if a little that is old and sweet is placed on the top. The quantity you name, if applied frequently, will be of much service. Occasionally the lining should be turned over, adding to it fresh material, and an increase of heat is obtained. Linings will not afford sufficient heat if the glass is not covered with mats during cold nights, two or three thicknesses often being needful. Early autumn is the best time for transplanting Hepaticas, but it is not necessary nor advisable to remove the plants every year. The same remark applies to the Iris you name. The young growths of Deutzias and Weigelas strike readily if inserted in sand, covered with a bellglass, and placed in a Cucumber frame. The soil must be kept moist, the cuttings shaded for a time, and the growths a

little firm but not hard when the cuttings are made. Ripened wood also strikes if inserted in moist sandy soil under a handlight in late summer or early autumn. Two-thirds of good turfy loam, one-third of cowdung gathered from the field in a dry state and rubbed through a sieve, and a tenth part of coarse gritty sand or wood ashes, form an excellent compost for Pansies in pots. Decayed manure from an old hotbed will do if you have no cowdung. We are unable to help you in procuring flower pots.

**Walcheren "Broccoli" (G. O. S.).**—We are fully aware of the accuracy of your statement. The first of the catalogues we opened on receiving your letter contained these words in reference to this variety:—"Sow in March for use in September," which confirms emphatically what we stated, that the Walcheren is more of a Cauliflower than a Broccoli. Why seedsmen class it as a Broccoli we do not know. It is certainly no more a Broccoli than Veitch's Autumn Giant Cauliflower is; indeed it is neither so late nor so hardy as that variety. But the seedsmen make themselves safe, for they class the Walcheren also as a Cauliflower, for it may perhaps be as well to state that it is the same variety that is included under both heads. We might have gone further and stated that the Walcheren is not a Broccoli at all; and most certainly it cannot be properly compared as to hardness with the varieties of which Wilcox's Broccoli is the type any more than the Paris Cos Lettuce can be compared in the same sense with the Hardy Hammersmith Cabbage variety. Relative to your other remarks we appreciate your prudence, and we wish all our correspondents were as thoughtful as yourself, but it is not for this reason alone that your communications are valued.

**Raising Seeds of New Zealand Flax (J. Sinclair).**—The seeds should be sown in light sandy soil, plunging the pots in moderate bottom heat in an ordinary propagating frame or other suitable position, and being careful to prevent the soil becoming dry. They usually germinate in about a month; but the time varies, as with all seeds, according to the time of year when they are sown. In an establishment near London, where very large quantities of seeds are annually received from a variety of climates, it is customary, if the consignments arrive in late autumn or winter, to sow a portion of each and retain the others until spring, as germination is then not only much quicker but frequently a great proportion of young plants are obtained from the same quantity of seed. The steeping you gave the seeds, so far from aiding them, has probably killed them.

**Marechal Niel Rose Unhealthy (F. R.).**—Your plant has become exhausted by profuse flowering, and in all probability the root action is defective, the soil perhaps having become sour by the constant applications of liquid manure that were necessary under the circumstances. Although you cannot "get at the roots" we should still endeavour to renovate the plant. The fact that it produced a "fine shoot" after being cut back in the autumn is both encouraging and suggestive, inasmuch as it affords reasonable proof that if the pruning had been still more severe than more than one young shoot would have followed, and if strong healthy growths of this Rose can be produced flowers are tolerably certain to follow. We do not quite understand whether the "fine shoot" to which you refer was produced last autumn after pruning or is a young growth of this spring; however, the point is not of great importance, only we consider that the autumn is not the best time for pruning this Rose, and especially when it is grown under glass. We have never produced so many and such fine blooms of Marechal Niel over a period of many years as by pruning severely immediately the blooms were all cut. When the pruning is done then young growths speedily follow (if the plant is healthy and root action free) that extend many feet the same season and become matured. Such growths if left their full length, or nearly so, are almost certain to produce a number of fine blooms. This, then, is what you must endeavour to encourage—young growth, and your only mode of succeeding is by shortening the main and weakly branches at parts where the wood appears healthy—nearly cutting the plant down, and then by syringing freely in bright weather new and probably strong growths will follow. If the fine shoot to which you refer was produced last year, and is flowering, we should cut it down too, leaving only four or five good buds at its base, from which you would be almost certain to have as many young growths that would mature this year and produce flowers the next. The pruning may be done now or after you have gathered the flowers.

**Sowing Peas and Broccolis for Succession (J. E.).**—It is impossible to give dates for sowing Peas for producing an unbroken supply, as this work must be decided in accordance with the weather, and to give tabulated information of all the varieties grown would be more bewildering than instructive to the majority of our readers. If you sow the first three varieties at the same time you will have a succession; but it would be perhaps better to allow a week to elapse between the sowing of the first two you have named, the others may be sown as soon as those immediately preceding them appear above ground. As a rule it is a great mistake to grow as many varieties as rows when a regular supply is the chief consideration, and where a blank in gathering causes disappointment. The most experienced gardeners never adopt this plan, because practice has proved to them that it is not a safe one. After ascertaining about three varieties that succeed best in the garden and give satisfaction at the table, they rely on these for affording an unbroken supply, and never fail in their object. New varieties are grown in smaller quantities for testing their merits and for ascertaining the time that is required for growing them for table use; the regular supply, however, is provided for without taking the novelties into consideration. The Broccolis you name sown on the dates mentioned may be expected to afford a succession of heads, except the first, which sown during March and April is a Cauliflower, as it will form heads the same season. You must, therefore, make further sowings of Walcheren in May and June, and even then there may be a blank between this and Snow's Broccoli; indeed this is sure to be the case if late-sown plants of the former are not protected in the autumn, as has repeatedly been advised in our "Work for the Week." Veitch's Autumn Giant Cauliflower sown in May often comes in between the Walcheren and Snow's Winter White Broccoli.

**Annuals for Exhibition (P. Henslow).**—It is impossible to name twelve annuals for growing in pots so as to ensure them all being in the best condition on a given day in August, as these flowers are much influenced by the season. Your only mode of securing your object is to grow more than you require, and sow the seed at two different periods, and then select the best pots. Very much also depends on the treatment to which the plants are subjected. Stocks and Phlox Drummondii sown now in rich soil under glass, would, with good culture, be fine in August. Rhodanthe maculata is very fine in pots when well grown. The seed should be sown in the pots in which the plants are intended to flower; to be grown in a cold frame and not watered over the foliage. Sow towards the end of May and early in June. Schizanthuses are very effective, *S. oculatus albus*, *S. tigrisoides*, and *S. atroviolaceus* being all good. Dwarf Tropaeolums, scarlet, crimson, and yellow, succeed well in pots, King of Tom Thumbs being the best. *Collinsia multicolor* and *C. Bartschiana alba*, *Collomia coccinea*, *Convolvulus tricolor splendens*, *Nemophila insignis* and *N. maculata*,

*Venus's Looking-glass*, *Kaulfussia atroviolacea*, *Leptosiphon densiflorus*, *Nolana paradoxa*, *Sphenogyne speciosa*, *Lupinus nanus*, *Linnm grandiflorum*, Dwarf Larkspurs and Clarkias, and the taller annual Chrysanthemums are all suitable for your purpose, and may be sown about the middle of May and early in June. A good display may be produced in 6-inch pots. After placing in the drainage fill the pots one-third of their depth with rich but not wet manure, pressing it firmly; then fill up with soil—good turfy loam and a third of manure. Water the soil thoroughly before sowing the seed, which cover a little more than its own thickness with fine soil. When completed a space of an inch must be left from the surface of the soil to the rim of the pot for holding water. Plunge the pots in ashes in an open position, and afford some protection during heavy rains and thunderstorms; otherwise permit full exposure night and day. Sow thinly and thin quickly, overcrowding in the early stages being ruinous to annuals. The soil must never be dry, and when the plants commence flowering clear soot water and liquid manure made from fresh cow dung will be highly beneficial. With this generous treatment, and not allowing any seed pods to form, the plants may be maintained in beauty over a considerable period. Easily as annuals are grown in the open ground, it is by no means a simple matter to produce them in superior condition in pots, and to effect this object they need as much attention and cultural care as plants do that are of fifty times their value. Poor soil, neglect in watering, and overcrowding are the "rocks ahead" in growing annuals in pots during the summer; avoid these and you may hope for success. When prizes are given for annuals grown in pots, the size of the pots ought to be named, otherwise the plants may be exhibited in pots ranging in size from 5 inches to 12 inches in diameter. In this event the judges ought to take into consideration the sizes of the pots when awarding the prizes, and not give the awards simply to the largest masses, as some in the smaller pots may show equally good or even better evidence of superior culture. It would be well for you to obtain, if possible, some explicit information from the secretary on the point before sowing the seed.

**Names of Plants (W. E. B. Bideford).**—1, *Fuchsia procumbens*; 2, *Pteris straminea*; 3, *Nephrodium decompositum*; 4, *Polypodium phymatodes*; 5, *Resembles Pellaea cordata*, but the specimen was insufficient to determine with certainty. (W. A.).—1, *Sericographis Ghiesbreghtiana*; 2, *Asplenium maximum*; 3, *Polypodium plesiosorum*; 4, *Nothochlæna flavens*; 5, *Asplenium furcatum*; 6, *Davallia Mooreana*.—(W. B.).—*Thujopsis borealis*. (H. A. T.).—*Acer rubrum*, the Scarlet Maple, introduced from North America in 1656, and is plentiful in many nurseries. (M. S. O.).—*Sparmannia africana*.

#### COVENT GARDEN MARKET.—APRIL 13.

In consequence of the holidays the demand for forced fruits has much fallen off, Strawberries being lower. A few samples of new Grapes to hand of inferior quality.

#### POULTRY AND PIGEON CHRONICLE.

#### THE UTILISATION OF WASTE LAND.

(Continued from page 282.)

A MODE of utilising waste land—by its entire reclamation from absolute sterility, or by improvement of tracts of but little value, although enclosed and turned to very little account—now deserves notice. The process we allude to is called "warping," which is made use of in certain districts bordering upon rivers and their tributaries. In order that this operation may be pursued with advantage several points are necessary—namely, that the general level of the country through which the river flows should be below

that of the tide at high water; and the water of the river should be subject to supply from extensive watersheds of cultivated land, in order that large quantities of alluvial matters may be flowing with the water, especially at the time of floods, and held in suspension when the water is penned and retained as a pond over the surface of the land to be warped. For this purpose the river water at low tide is allowed to flood the land by means of outlets in the banks of the river and prepared channels and sluices, and it is then kept there until it has deposited the mud or silt with which it is charged. When this has taken place the clear water is allowed to flow away by other channels and return to the river. Fresh quantities of water are then admitted at every succeeding tide, each of which produces a new superstratum of sedimentary matter, and this operation is repeated until the requisite thickness of the warp has been obtained. The quantity of warp so deposited by each successive tide in many cases exceeds one-tenth of an inch in thickness. It varies, however, greatly at different periods of the year, according as there is little or much flood water in the river and in the position of the land. By these means there is often created in the course of a few months a new soil of considerable depth, which will consist for the most part of the various kinds of earth and undecomposed vegetable and animal matters which the waters of the river have collected and borne along in their course. Land thus warped is said to possess a natural power of production of the most remarkable kind, and a degree of fertility far exceeding that which is obtained by any of the ordinary processes of cultivation; in fact, large tracts of perfectly sterile land, such as sandy and peaty soils in the neighbourhood of the rivers Humber, Trent, and Ouse, with many others on various parts of the seacoast, have yearly been converted into good land solely by the agency of these operations. Still there are large areas capable of being reclaimed in the same way under similar circumstances, which in most instances if properly managed might be rendered profitable either as arable or pasture land.

As we must consider the question of warping and reclaiming land, especially in those cases where the mouths of rivers meet the tides, it will be necessary not only to refer somewhat minutely to the general question, but also to the advantages to be derived by the owners of seaside property by enclosing and reclaiming mud lands, and before concluding we shall refer to dry warping. Although warping has been only known in England for about 130 years, having been first practised near Howden on the banks of the Humber about the middle of last century, and brought prominently before the public by a Mr. Marshall in 1788, yet it has been long followed on the continent with great success under a different name, and is thus described by a Mr. Cadell in his "Journey in Carniola":—"In the Val di Chiana fields that are too low are raised and fertilised by the process called *colmata*, which is done in the following manner:—The field is surrounded by an embankment to confine the water; the dyke of the rivulet is broken down, so as to admit the muddy waters of the high floods. This water is derived only from the streams which flow into the Chiana, and is allowed to deposit its mud upon the field. The water is then let off into the river at the lower end of the field by a discharging source. In this manner a field will be raised  $5\frac{1}{2}$  and sometimes  $7\frac{1}{2}$  feet in ten years. If the dyke is broken down to the bottom the field will be raised to the same height in seven years. It is found that water which comes off cultivated land completes the process sooner than that which comes off hill and woodland. Almost the whole of the Val di Chiana has been raised by the process of *colmata*."

Take for instance the counties of York and Lincoln, which illustrate also various portions of other districts. Not only are they both more than half surrounded by water, but the greater portion of the country so situated lies below the level of the sea, from the encroachment of which, indeed, it is only preserved by extensive

walls and embankments. The water of the rivers that flow through such a district, as may be naturally supposed, is highly charged with fine mud and silt, admirably adapted for the purposes of the warper, who conducts his operations as follows:—After an excavation has been made in the river bank a dyke, and sometimes raised embankments, are built to guide the water from the river to the land to be warped. In order to confine the water to any particular spot and prevent it overflowing the adjacent country the land is divided into compartments of about 20 acres in extent by strong well-formed banks, which are of the same height as those of the main feeding dyke. In this way each flood tide is conducted into every one of the compartments in succession, and as it ebbs the hydrostatic pressure of the water alone suffices to force open the swinging doors of the return sluices, thus allowing itself to escape in the main canal, and thence into the river, after having deposited nearly the whole of its mud upon the surface of the enclosed land.

By the above plan it has been found possible to warp land in one year to the depth of from 2 to 3 feet, and this is generally considered to be quite deep enough, and is permanent in its action. This statement, of course, only applies to those lands which are sufficiently below high water mark; where the level is higher a longer time—often from two to three, and sometimes even four years—is required. In the year 1825 the Society of Arts voted a premium, consisting of its large gold medal, to a Mr. Ralph Creyke, jun., for his description of the process of warping by an improved method a tract of 429 acres of peat moss. The superiority of his process over those ordinarily followed consists in creating a fine deep rich soil more effectually upon a larger scale and in a shorter time than has hitherto been practised. According to the usual practice the tides are only admitted during the months of August, September, and October; but by his plan they are admitted all the year round. Usually the sluice is not made more than 5 feet wide; his has two openings of 16 feet wide. The main drain is usually only 12 feet wide; his is 90 feet wide. Not more than about 14 acres are often embanked in one piece; he has enclosed 500 acres in one compartment. Formerly not more than  $1\frac{1}{2}$  foot of deposit was obtained; he has got from 3 to 5 feet upon the increased quantity of land. Scarcely any inlets used to be made for the purpose of spreading the tide water quicker and more equally over the surface of the land within the embankment, as well as for the speedy return of it upon the ebb. In all his practice innumerable inlets are formed for this purpose. It is necessary to keep all warped land thoroughly drained; and as in various cases it is found advantageous to sub-irrigate the land, it is desirable to set out the drainage with this double object, so that in extremely dry seasons the tide water may be admitted to percolate the drains as occasion may require. We have pursued this plan with open drains on our own marsh land with good effect.

The process called dry warping consists in the spreading and covering land with other soils to a depth of from 6 to 9 inches according to circumstances, and thus converting barren or inferior into fertile land. A remarkable illustration of this is afforded us in the utilising of Hatfield Chase, which was a peat moor of about 4000 acres lying above the level of the neighbouring corn lands. An Act of Parliament for enclosing the moor was obtained about seventy years ago, though for what object at the time it was not easy to see, as no one could then have anticipated the possibility of making this hitherto impassable morass of any value. By the construction of public and private enclosure drains it gradually became firm land, and the existence of an old river course—the waters of which two hundred years ago had taken a new channel—was remembered, and a Mr. Hatfield Gossip, who owned a considerable part of the moor, conjectured that this old course would contain rich alluvial matter deposited by the tides from the rivers Trent and Humber. He conceived the idea of covering the whole moor with this, and to his perseverance and skill in carrying it out we are indebted for the practical exposition of the advantages of dry warping. The process pursued was to form a railroad from the pit (or excavation into the alluvial deposit) over the moor, with branch rails leading to the parts to be improved. "A stationary engine drew up from the pit the loaded waggons, which were then taken by a locomotive engine along the main line, and passed by the branches to the required spot. Here the waggons were tilted over, and the soil spread to a depth of 6 or 8 inches. When the moor for 7 or 10 yards on each side of the branch was covered, the rails were removed by a machine traversing the line and taking up the separate pieces of rails and deposited them in a fresh line with the greatest expedition and facility, and thus was seen a sheet of firm and fruitful soil steadily spreading over this once hopeless quagmire." The advantage of a well-drained substratum of peat has been long appreciated for grass crops.

Here the fresh coating of rich soil produces a slow decomposition of the old vegetable covering of the peat as well as of the peat itself, and the roots of grass or other crops striking deep into these always find moisture and nutriment. The effect has been that most astonishing crops of Clover, Turnips, and particularly Beans, have been grown on the newly warped land, and that grass is green in the driest seasons and possesses peculiar milking and feeding qualities.

#### WORK ON THE HOME FARM.

*Horse Labour.*—Barley sowing should now be completed in preference to any other horse labour, because we have found it difficult to obtain a good stout grain fit for malting when the seed has been sown after the middle of the month of April. The same remark applies to sowing Mangold seed, especially upon the hill farms, for two reasons; first, because on the elevated chalk soils the growth of root crops is always slow even in summer; secondly, unless the seed is sown whilst the ground is moist, the seed may not vegetate until sufficient rain falls, and if rain should be delayed the loss of the crop must certainly ensue. A striking instance of this occurred to the Mangold crops of last year, large areas of land being ploughed and re-sown with other root seeds in consequence of the weeds making a great growth whether the Mangold seed vegetated or not. Clover seeds should be sown at the same time as the Lent corn, except in those cases where the corn is drilled at 12 inches apart between the lines, for the seeds may be then sown before the hoers, in order that in destroying the weeds the Clover seeds may be buried at the same time. The mixture of seeds we prefer is broad Clover and Alsike, with some Saintfoin, but no Rye Grass; in the alternation we sow white Clover, yellow Suckling, and Cow Grass; when, however, the land is required for feeding off during two or three years we choose a mixture of white Clover, Timothy Grass, Hard Fescue, Sheep's Fescue, Cocksfoot, and Pacey's Perennial Rye Grass. If the land is in good condition, and especially if the seeds are sown after a Wheat crop, this mixture will produce capital turf for stock-feeding until required for corn, as it would be in the five or six-course rotation after bearing grass for two or three years. In order that the land may not deteriorate, all stock should be allowed to have cotton cake whilst depasturing the old leas; for referring to Mr. Lawe's statement, the value of the manure derived by the feeding one ton of decorticated cotton cake amounts to the sum of £3 12s. 6d., quite irrespective of any advantage derived by its consumption by cattle or sheep. In drilling Cabbage or Thousand-headed Kale seed upon stretches manured and prepared for the purpose of retaining a plant for the future crop, the further object may be attained of providing plants for transplanting in other fields if the land is kept clean by continued horse-hoeing between the lines, and hand-hoeing in the lines. A double number of plants may also be left on the stretches when hand-hoed, so that a large number of plants for transplanting may be available by pulling every alternate one and yet reserving a full crop on the stretches. This plan to a certain extent will obviate the necessity of sowing the seed on prepared beds or borders.

*Hand Labour.*—At this time of year peat may be dug where peaty meadows or waste occurs, with a fair chance of drying them fit for storing for future use. This is not only available as fuel for the cottagers or on the farm, but in pasture districts where little arable land is attached to the farm we recommend dried peat as a substitute for straw in the cattle pens; it is an absorbent, and by proper management will contribute to both the health and cleanliness of the stock. It is also valuable in the land as manure, because, unlike other kinds of earth, it does not contain the seeds of weeds.

*Live Stock.*—At this time it is customary to purchase stock for feeding on grass lands of certain districts, and the home farmer should observe the policy of feeding cattle on his pastures instead of sheep for two very substantial reasons; first, because sheep destroy or injure the finer herbage, and are more liable to suffer from the fluke rot than cattle. Horned cattle occasionally suffer from the fluke, but it is chiefly due to close feeding upon very wet land. In stocking the farms with dairy cows some farmers are accustomed to purchase by commission to a dealer; and as the cows which have been taken to the metropolitan market to be sold are often the finest dairy cattle in the kingdom, it is not an advisable practice, as they often contract disease. It is an advantage that through restrictions they cannot as usual be sent there for sale, and in consequence purchasers should give their orders to trustworthy commissioned men, and have their cows conveyed into the district by railway. In the same way young stock of the best quality may be obtained either of heifers or steers; for although they are enabled to travel better and with less injury than dairy cows, yet they often pass through districts in which they take the germs of some disease; at any rate, they are subject to the disturbance and irritation of a long drift, which often reduces their condition as well as their health.

#### VARIETIES.

**POULTRY SHOWS AND PRIZES.**—It is a great pity that the Birmingham Dairy and Poultry Show in June will clash with the Bath and West of England Show at Tunbridge Wells. We have both the schedules for poultry before us, and cannot help thinking that the Bath and West of England Society has been ill-advised to

reduce its prizes so much. Cups and special prizes seem entirely to have disappeared from the list, and save in the case of Turkeys, which have £2 first prizes, no first prize is more than 30s. Considering the length of the Show, and the fact that the entry fee is 5s., and that the place of Show involves birds from the greater part of England travelling by at least two lines of rail, the 'schedule does not strike us as a tempting one.

— **THE LATE MR. FRANK BUCKLAND.**—Prince Christian has joined the Committee which has been formed to raise a memorial to perpetuate the services rendered to the study of natural history and fish culture by the late Mr. Frank Buckland. Subscriptions will be received by the Hon. Secretaries, Lieut.-Col. Bridges and Mr. T. Douglas Murray, at 34, Portland Place, W.; by Messrs. Cox & Co., Craig's Court; and at the office of "Land and Water," 176, Fleet Street, E.C.

— **ARRIVAL OF SUMMER MIGRANTS.**—Dr. D. G. F. Macdonald writes to the *Daily News* under date 9th inst., from Woodford, Essex:—"In spite of the cold winds the bright sunshine has lured our summer migrants to their old haunts, for I was welcomed in Epping Forest by the sweet notes of the cuckoo and the nightingale this morning, whilst swallows and martins flittered over the pretty glades and russet slopes, with all their wonted gracefulness."

— **HOMING PIGEONS IN GERMANY.**—From time to time, as subjects for leading articles fail, the daily journals treat us to disquisitions on "Carrier Pigeons." Often very amusing they are, and singularly misleading to the uninitiated. In a late number of the *Daily Telegraph*, however, we read an article far in advance of the common knowledge of the subject, and in which were some interesting facts concerning the careful maintenance of Homing Pigeons for military purposes in Germany. After some poetic contrasts between the bird of Mars and the bird of Venus we were interested with the following on the PIGEONS' BATTALION IN WAR.—"Looking about for improvements in war, the great military empire (Germany) has remembered the Carrier Pigeon, and, with complete fidelity to the swift-winged bird's traditions, has taken it from the easeful lists of love to the stern realities of the battle field, and made it once again the messenger and the emblem of strife. Often before in the East, and during the Franco-German war sometimes in the West, the Pigeon had already been thus employed; but it has remained for Germany to recruit the bird formally into the ranks, to give it depôts and étapes, lines of communication and bases, a military organisation for the field and another for peace times, to settle precisely its place in cantonments and in camp, to tabulate its military duties, and to draw up schemes for its commissariat and transport. With their head-quarters at Cologne, these birds of war have had mapped out for them in a regular scheme of lines and cross-lines the services they will have to render; and 'the Pigeon battalion,' therefore, ranks from to-day as a standing feature of the German army of the future.

— **STRAWBERRY FARMING IN AMERICA.**—There are now under cultivation around Charleston, S.C., within a convenient distance from the railroad depôts and wharves, about 250 acres of Strawberries, which will, with a favourable season, furnish for shipment to New York alone 1,000,000 quarts of berries; about 1500 acres of Potatoes, with an aggregate probable out-turn of 60,000 barrels; about 300 acres of Tomatoes, and about the same number of acres in Peas and Beans. These farms are highly cultivated, and are a source of great profit to the owners when they can get the crops to market early in the season. The Strawberry crop, which is the most valuable, is well advanced, and the season promises to be early, and consequently profitable.

## POULTRY AND PIGEONS

#### THE DORKING.

I READ with much interest Mr. Cresswell's admirable letter on the Dorking fowl, and only hope that from it, and the correspondence to which it may give rise, breeders may arrive at some definite and satisfactory conclusion as to what is really the most

desirable type of Dorking. I have always liked to look upon the Dorking as holding a position among poultry similar to that of the Shorthorn among cattle. In many respects their points are analogous—viz., early maturity, large size, great natural inclination to put on flesh &c., and, what I consider of most vital importance, a strong tendency when crossed with inferior stock to transmit much of their own excellence to their progeny. Regarding the Dorking fowl from this point of view, I fail to agree with those who write as if it should be judged solely as a table fowl by the delicacy of its meat. This is certainly an important point, but at most it is only one point out of several which go to make up a perfect Dorking. Everyone knows that if judged by quality of meat alone the Shorthorn would take a comparatively low place among cattle, being far surpassed in this respect not only by West Highland, Black-polled, and other pure breeds, but also by many crosses, and to decry our Dorkings because other fowls can be found excelling them in this one point seems to me to be much the same thing as to condemn the Shorthorn *in toto* because it does not produce the finest grained meat in the Christmas markets. If, as I believe, Mr. Tegetmeier is relying on a Dorking cross (such as won in the table poultry class at the last Crystal Palace Show) to produce a superior table fowl such as Mr. Weir refers to, this only strengthens my case. As to size, Mr. Weir's argument as to great size, being of itself a drawback from a table point of view, will, I think, hardly bear investigation. A Turkey is universally admitted to be a most excellent bird for the table, and yet I venture to say that no one would think of offering a lady the whole of the liver wing of a good large Turkey on account of its size. Several ladies may dine satisfactorily, however, off one side of the breast, and this also applies to a good Dorking.

Although a Scotch fancier I cordially deprecate any value being attached to a red ear in Coloured Dorkings, and in my own experience I have almost always found that the best birds had at all events a tinge of white. If required Dorkings could of course in time be bred to red ears, but even if no cross was used to effect this object it would entail, temporarily at least, the sacrifice of many more important points. Of this fancy for red ears to which Mr. Smyth refers, together with a strong tendency to make the Coloured Dorking a bird of feather, and that too of the darkest possible feather, we are now beginning, in Scotland at least, to feel the effects. At present, under some judges in the north, a light-coloured bird appears to have hardly any chance, unless all the dark ones are very much inferior. At some shows indeed, whether designedly or not I do not know, the term "Dark Dorking" has taken the place of that of "Coloured Dorking other than Silver Grey" in the prize lists.

No doubt it is far more pleasing to the eye to have one's flock of Dorkings all of the same shade of colour, still I think this point might more advantageously be left to the taste of the individual breeder. There are many shades between the extremes of light and dark; and if the only restriction for an exhibition Coloured Dorking was to a sound rich colour and handsome appearance, this would include all that is really necessary, and by leaving each breeder very much to his own discretion would save many a grand Dorking fowl from being drafted—its inevitable fate if an arbitrary colour standard should be generally adopted.

Sooty feet are another important point, and I can't help thinking indicate, in some cases at least although not always, a cross more or less remote. Yet here again I would be in favour of some discretion being left to a judge. In pullets more especially I have noticed many good birds to have dark feet as chickens which in the second year became perfectly white. In such cases it would be rather hard absolutely to disqualify a pullet which in another year might win a cup at the same show as a hen with white feet. Old hens might fairly be more severely dealt with, and also cocks of all ages. I have never bred a cockerel with sooty legs or feet, but feel pretty sure that from hens being as a rule more liable to it, the fact of a cockerel having dark feet would prove the fault to be so inveterately established in the strain that it would warrant a judge passing over an exhibit, even if only for the sake of checking the spread of the defect.—J. T. CATHCART.

I CAN confirm what Mr. Cresswell says of Dorkings being an excellent substitute for young Turkeys. Three years ago, in the month of June, a poulterer with whom I had been long acquainted came and asked me as a special favour to let him have any very early Dorking chickens I could spare, quality being no object so long as they were big. I happened to have three or four faulty birds weighing about 5 lbs. each, which I had killed and sent to him. I was much surprised at the very liberal price he paid me for them. Some time afterwards I discovered that the poulterer

had received an order to supply some Turkey poults for a military ball supper, and, not being able to obtain any young Turkeys, my Dorking chickens had taken their place. I can answer for it that no one ever discovered the difference. I have always understood that in the present day the great object is to produce the animal or fowl that comes soonest to maturity, and in this respect I consider the Shorthorn and the modern Dorking excel.—M. F. SMYTH.

## PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 284.)

### GENERAL PRINCIPLES.

WE have next to consider the question of the age of the breeding stock in reference to mating them. Very young birds should not be bred from, and it is best to mate cockerels and pullets with older birds. As the season advances and the birds of the previous year have become fully matured this is of less importance, but for early hatching the mating of a cockerel with pullets should be avoided. The progeny are almost always more delicate than those bred from yards where at least one parent bird is fully matured. It may be objected that there is a difficulty in getting hens to lay early in the season, and that there is a still greater difficulty in getting fertile eggs from pullets mated with an old cock. To this we reply that as a rule both difficulties can be got over. If care be taken to induce an early moult in the hens they will probably be ready to lay just as early as the pullets. If the cocks be separated from the hens during moulting time, and only put with the pullets a short time before the eggs are wanted, there will generally be a fair number of fertile eggs. Another method which we have adopted with success, and which we have not seen suggested elsewhere, is to select from amongst the later cockerels those that are most promising and keep them running together apart from hens or pullets until their first adult moult; these birds are then used to mate with the pullets selected for early hatching.

The method of hastening the moult of the hens is as follows:—If the hen be of a sitting variety she is just as the moulting season approaches encouraged to hatch, and given a few eggs to sit upon. She is either allowed to hatch and rear a few chicks or to lie four or five weeks on the nest. When she leaves the chickens or comes off the nest, as the case may be, she is placed in an extra warm house or pen and given a little hempseed with her other food; this generally produces the desired effect. With hens of the non-sitting varieties, and with cocks, the latter part only of the treatment can be adopted, and it is not always successful, but a sufficient number of birds to supply eggs for early hatching can generally be moulted through by these means.

Although it is best to mate birds in their first year with older ones there is no objection to mating birds two, and in some breeds even three, years old with each other; these often produce the finest chickens. When a valuable bird begins to get old, however, it is generally necessary in order to insure the eggs being fertile that the mate or mates selected should be young.

When birds are found to "hit well together," or in other words to produce valuable offspring, it is as a rule best to allow them to remain together as long as considerations of age will permit. We have seen a theory advanced in respect to the breeding of larger stock, that it is only by this permanent mating that the best results can be obtained. There is no doubt that traces of previous alliances often appear in a most inexplicable manner, and it is hard to say with certainty that any length of time will quite obliterate the effects of an alliance. What is known as "the influence of previous sires" has been much discussed from time to time, and arguments have been adduced in support of a theory that the ovum may be partly fertilised by one alliance and the fertilisation completed by another. We once had a case in our yards which did much to convert us to this doctrine. A Silver-Grey Dorking cock paid a visit to a yard of Dark Brahmas; he was at once discovered and ejected, and steps were taken to render any further trespassing impossible. All the eggs from the Brahma hens were being set. From those of one of them we produced one regular cross-bred Brahma-Dorking chicken, and a series of five or six others showing gradually less of the Dorking and more of the Brahma, until at last one—a pullet—was of good Brahma shape and colour and well pencilled, and only showed the Dorking taint by having five toes on each foot.

Some of the French fanciers recommend a method of breeding which indicates a concurrence in the theory that the influence of more than one male parent may affect the offspring. They adopt the plan of running two cocks on alternate days with the same hens. These cocks are chosen with a view of mutually counter-acting each other's defects and thus producing chickens with the

good points of both. This method may under some circumstances be worth a trial, but we should only be inclined to resort to it where no other was available.

Partly, then, from a belief that it is only by permanent mating that the best results possible from an alliance can be obtained, and partly upon the more practical ground that it is well to make the most of a successful hit, we recommend that a suitable alliance should not be disturbed.

Another matter upon which there has been much discussion may also be mentioned—namely, the effect of the imagination or the visual impressions of the parent upon the offspring. Sufficient evidence has been adduced in favour of the theory that the close proximity to the hen of birds of a very different colour to her own may affect the colour of the chicks, to make it worthy of the attention of the breeder to take care that all risk of such impressions be avoided. If birds of very different colours are running next each other it will be well, therefore, that the fence between them be of such a character that they cannot see each other.

(To be continued.)

### BUFF COCHINS.

I HAVE been much interested in the discussion which has recently been going on in your columns as to the points of the Dorking. Such discussions do much to clear the ground of doubtful matter and to give uniformity to the decisions of the judges. Personally I am not concerned with the Dorking, my breed being the Buff Cochin. I should like to see recorded in your columns the opinions of leading Cochin fanciers upon a point which a few seasons back gave rise to much uncertainty, and which even now is by no means clearly settled—namely, Are tricolored Buff cocks to be admitted to the prize list?

A year or two ago a very fine bird of the tricolored sort experienced great vicissitudes of fortune. At several shows he stood at the head of the list, while at others he was amongst the unnoticed crowd. His merits as a Cochin were undoubted, but the three colours threw him out with some judges. Now, whilst admitting the striking effect produced by the contrast of colour, I am inclined to think that the judges who pass over birds of this type are in the right. My experience has been that such birds do not breed evenly coloured pullets, and I think that the uniformity of colour which is admittedly indispensable in the one sex should be equally insisted upon in regard to the other. Perhaps some of your readers will give us the benefit of their ideas upon this subject.—BUFF.

### CROSS-BRED POULTRY.

THIS is a matter about which I should be glad of information as the results of one or two experiments have not been satisfactory. Here in Mid-Sussex every cottager's wife rears chickens for market in large numbers, and all of them are cross-bred. The hens used originally were those termed Sussex, not unlike the Dorking in their handsome shapely bodies and short legs. Many of the chickens revert to the original type now, while others develop greater length of limb owing to the cock almost invariably being of the Brahma type and not unfrequently pure Brahma; for weighty birds are required for market, and such are undoubtedly the result of this popular Sussex cross. A ready sale is always found for them, the early spring broods being the most profitable, poultry dealers making long rounds in search of them, and giving 8s. a couple at the cottage door for chickens that are subsequently fattened for market by the dealer.

Having to provide and maintain an abundant and regular supply of chickens for table, this local breed was adopted by me with confidence, and no difficulty was experienced in rearing and fattening them. The chickens were large, heavy, and remarkable for an excess of fat as they attain to full growth, but the older ones were so strongly objected to upon the score of coarseness that I resolved to try a cross with a Game cock and Dorking hens. I had heard the cross highly commended as producing chickens of that fine quality of flesh and delicacy of flavour so dear to the palate of a connoisseur. The result was the reverse of satisfactory, for the chickens proved so delicate in constitution that a large percentage of every brood were lost soon after hatching, and the survivors grew so slowly and were at best so undersized that the cockerels were crowing away lustily before they were big enough for table, and at their best they were miserable starvelings in comparison to the noble Brahma-Sussex chicks. The Game cock was a splendid fellow, but he came to an untimely end, and the whole of his progeny were got rid of. He was replaced by a fine Dorking cockerel two or three months ago, and from the appearance of the early broods of Dorking chickens I think the

change will answer. Meanwhile care has been taken to establish enough of the Brahma-Sussex fowls in another yard to ensure a supply of chickens, and I cordially commend them to the notice of all who require large hardy chickens and are not very critical about points of delicacy and flavour in the flesh, which is certainly tender enough.

I may add that we do not depend upon any of the fowls named for the egg supply, a considerable number of Silver-spangled Hamburgs being kept solely for that purpose, and especial care is taken to rear enough pullets of the Hamburgs early to afford a supply of eggs in winter when the old hens cease laying.—EDWARD LUCKHURST.

### HOMING PIGEONS.

MR. HUIE's letter in your last issue cannot fail to be interesting to every Pigeon fancier. The fact which he relates so circumstantially that there seems no possibility of there being mistake in it, of an untrained Pigeon having flown from Ledbury to Scotland, can but lead one to conclude that there is something more than sight which directs the flight of the Homing Pigeon. I do not pretend to be experienced in this race; still several facts which have come under my notice in the case of various Pigeons have long inclined me to believe that instinct—I do not mean the highly developed instinct of the migratory bird, but a sense apart from sight and unexplainable from experience—does aid the flight of Pigeons. I will relate one case, by no means carrying the strong proof of that given by Mr. Huie, but still presumably favouring the instinct theory. I had as a boy some indifferent dark blue Fantails, the hen an old favourite, the cock young. I gave them to a servant to send away and thought no more about them; five weeks afterwards I found the hen quietly feeding in her old quarters. I inquired where they had been sent, and found that they had gone to the east of London, about eighteen or twenty miles from where we lived in West Middlesex. They were confined for five weeks; but accidentally one day the hen escaped, and by noon the next day we found her in her old quarters; she had within a few hours crossed the great city and reached her old home fourteen miles beyond it. The bird had been given to me, and as a nestling had never been taken in her life off our premises; and as every fancier knows Fantails are not high and experimental flyers, so it seems next to impossible that she could ever have been at a height to see twenty miles. Such an instance is of course only a small gain in cumulative proof, but two or three like that given by Mr. Huie would go far to establish a fact contrary to the almost universal belief of fanciers.—O. E. CRESSWELL.

### OUR LETTER BOX.

**Illustrated Poultry Book** (F. G.).—"The Illustrated Book of Poultry," published by Cassell, Petter, Galpin, & Co. It can be obtained in fifty 6d. parts, or bound, price 31s. 6d.

**Uncooked Rice as Food for Chickens** (*Idem*).—Uncooked rice is very bad for young chickens, partly because upon becoming moist it swells greatly, and partly because there is so little real nourishment in rice. We only use rice occasionally as a check to any tendency to diarrhoea, and it should for this purpose be thoroughly boiled in milk.

## LECTURE ON THE AURICULA.

[Delivered by the Rev. F. D. HORNER at South Kensington on Tuesday last.]

AM asked to say a few words to you this afternoon upon the Auricula, which is a special feature in the Flower Show, contributed by the members of the National Auricula Society. With the flower in its beauty before you, my pleasant task can only be to say of it that which it has no power to express for itself. Mere praise to its very face would be as idle and unhappy as holding up a coloured picture to the inimitable original in life. But something of the past history of this flower, and something of the qualities that constitute its grace and beauty in the eyes of those to whom it is a very dear favourite, will add, I trust, to the interest with which you will regard and remember our flowers to-day.

This plant has so long been under the care of man, that like his domestic animals, though sprung from a naturally wild and hardy thing, it would not live apart from him, and without that attachment on his part which it seems to so faithfully appreciate and reward.

Some of the plants here to-day you have been wont to see in their accustomed place season after season, some even in successive shows. The Auricula is among them for one brief spring day—rare enough to be a floral phenomenon. It flashes into sight like some meteor across the sky and is gone. It is apparently a new comer, but in reality it is one of the very oldest of show flowers; for there were exhibitions of Auriculas in Lancashire more than 150 years ago. Indeed, to anticipate a little, I might have brought you a plant of a venerable sort called “Jingling Johnny,” shown at Eccles, then a straggling village near Manchester, a round century since. But the public career of the “Jingler,” as he was familiarly called, is closed, his long days nearly numbered, and no reasonable extension of a class list could now set him up again on a pinnacle of floral fame. Now we are accustomed to see such excellencies of form, colour, and habit in exhibition plants as are not found in the uncultured species from which they may have sprung. But in so high degree have all these points been gained in the Auricula that it is nothing short of an acquired flower, developed past resemblance to any wild original.

I propose to divide my subject into three sections, and will trust to make none of them too tedious for your patience. The first shall be upon the derivation and history of the flower; the next, the Auricula from a florist's point of view; the last, a very brief touch upon its culture. Not that I have any secrets which brevity should conceal. If there are any among my

hearers who so far only regard this flower with a cold and distant admiration as a new and rather curious feature in a flower show that ought to have novelty now and then to keep it up, I shall be glad if in any degree I can show them how very much more than this a flower is to those who love it.

DERIVATION.—In the botanical census by which plants are grouped according to natural orders the Auricula is classed with the Primulaceæ. The family is a large one. Some of its members bear such resemblance to our most familiar type, the Primroses, as to be easily recognised for Primulas; others are apparently so far removed both from it and from each other as to seem no blood relations at all, but only distant connections in law—botanical law. However, I shall not here introduce a larger circle of the Primula family than may interest you as showing the resemblance and dissimilarity of consorted plants.

The nearest native relatives of the Auricula are the Bird's-eye Primrose (*P. farinosa*), frequent in the north of England in marshy places and on the broken banks of little moorland rills; and also *Primula scotica* of Sutherland and Orkney. But after the Cowslip and Polyanthus, what a mixed group the Primulaceæ appear! The Cyclamens belong to it, and the more aspiring Dodecatheons of America, with their not far dissimilar flowers clustered on tall stocks, as if they were the bold Oxlip form of the Primrose Cyclamen. Another classmate is the Anagallis, *A. arvensis* being the red Pimpernel of our arable lands, and *A. tenella* the slender little beauty that threads its way daintily among the green mosses on the peaty moors. Bitter marshes by the sea contribute a member to the order in the Sea Milkwort (*Glaux maritima*); while in that lovely aquatic *Hottonia palustris*, the Water Violet, we see the Primulaceæ taking a decided plunge under water, and here as it were a veritable mermaid Primula. Thus, from the top of a mountain to the bottom of a pond we have Primulaceous plants as widely separated in habitat as in habit. Besides the Primula Auricula of the Alps, the remote ancestor of our cultured flower, and one given by Paxton as *hortensis*, a European plant with name suggestive of some degree of cultivation, and flowers described as variegated, there are several Primulas of Switzerland and Southern Europe interesting as bearing a resemblance to the Auricula on a small wild scale. There is *P. marginata* with serrated mealed foliage and lilac flowers with rudiments of that meal in the centre, which is so intensely developed in the Auricula. Also *P. Balbisii* with a habit of foliage in white and green quite that of the Auricula, and half pendant flowers “like Cowslips wan that hang the pensive head,” and also slightly mealed in the eye. Again, *P. intermedia*, *P. pubescens*, *P. viscosa*, *P. villosa*, and others with pink and purplish flowers, have the habit of diminutive Auriculas. Still all primitive and allied forms are a far remove from the derived flowers of so long a period of culture as extends over three hundred years, for Gerard states that prior to 1597 there were Auriculas in English gardens. These early varieties were yellows, browns, and purples; and as you look upon the beautiful flower to-day in its jewellery of emerald and pearl, and its velvet textures of many lovely colours, you will wonder how all this investiture of different orders of beauty descended upon a little pale wild flower of the Alps. The first advances from the purely wild type were the results of carefully seeding this sportive flower, which in its attribute of infinite variability from seed has the fundamental qualification for being what is known as a florist's flower. But

more full and rich in illustration of this than written history could well be are the interesting revelations which the Auricula makes to the raiser of seedlings.

In them the history of the past will repeat herself in varied retrospect, and among those that must be discarded as missing the standards they were meant to equal or excel are many whose faults are but tracings of their derivation towards its distant source. They show how petals now substantial, round, and flat, had been flimsy, frilled, and pointed, the white meal thin and ill-defined, the curious edge of green a slight and broken rim.

**HISTORY.**—In a glance at the history of the Auricula there comes, of course, the interesting question of its first introduction into England. When is perhaps not so exactly known as where, on which point there is the evidence of well-kept local tradition corroborated by local evidence that its early English home was especially Lancashire.

It is known that Flemish weavers in woollens, driven from their country by persecution for their faith's sake, settled about 1570 at Norwich, Ipswich, and in Lancashire villages in the neighbourhood of Rochdale and Middleton. As things of home too dear to leave behind them, these refugees brought with them their favourite flowers, the Tulip and Auricula. It is no matter for surprise that for about fifty years after this we have no record of Auricula culture. These early growers would doubtless for a time be shyly looked upon as aliens, and it would lead them to keep their occupations and interests a great deal within the bounds of their own communities; but in 1725 we have evident proof that the culture of the Auricula was established in Lancashire.

Parkinson in his "Theatre of Plants," 1640, names twenty-five varieties of Auricula Ursi, or Beare's Ears, or French Cowslips. They are described by colours such as Heaven's "blew," striped and double purple, blood red, sundry blushes, paper white and yellowish white, &c. In an old manuscript of 1732, and which was published in the "Florist" many years ago, Beare's Ears or Auriculas were quaintly classed as "pures," probably what we should call selfs; "flakes or stripes," which I confess I do not recognise by the description; and also "bizarrs," spoken of as admirably variegated with meal and colours, and raised in England or brought from thence.

Auriculas were grown abundantly in the Lancashire districts until about 1830, when a great change in the habits of the people, who were hand-loom weavers, began to take place. Steam power and the factory system were being developed about 1825, and during the transition from hand to powerloom weaving, those whose bread "came through the shuttle eye" felt the change severely, and numbers of them were for a time in great distress. From the handloom that filled the long window they could now and again in the day break their time and work longer at night, and in this way their favourite flowers received the most constant attention, which at the same time refreshed the toiler himself with a healthful winsome recreation. But the long peremptory hours of a factory day rendered all this impossible. The great hard-featured mills grew up over green fields and garden grounds, mammoth organisms in brick and mortar, stone and iron, seeming, in their high chimney stalks, to send up a mighty hideous sort of flower stem, blossoming with black wreaths of smoke and a sulphurous perfume. Then the scattered villages grew and conglomerated into towns—the light of the old hand-weavers' windows died out, and seemed to be concentrated in the gas-light glare from the long stages of windows in the mills—the familiar clatter of the handloom ceased, and the click of the shuttle that wove the silk or wool, as the tick of the old clock spun out the time. Under the changes of those days many ceased to grow their old favourites for lack of time or space, and also because they would not see the flowers languish under any unwonted neglect. Their little shows had nothing of the grand accessories that are here, but the very spirit of vitality was in these florists in their sincerity, patience, and love. The shows were held in the upper room of some old inn, and made a very lively sensation for miles around—a stir like a village wake or fair. What excitement it was for the anxious exhibitors assembled in the room below to wait for the winning plants being sent down from the "upper element" where the judges were deciding fates! In the later part of the day followed songs and anecdotes and florist gossip; and at going-home time the assembly dispersed with the first-prize men conspicuous by a gleaming copper kettle in hand. Always kettles for the best flower in the room, and for the first in every class. Perhaps none was a prouder man that day than he who as a new beginner carried the "colt's kettle" home!

The Auricula has been a flower neglected for many years till lately. For inexorable causes such as those that parted it from old friends like these we can feel sympathy, but not for every reason that has made it now so scarce. Mr. Lightbody, whose

name is so associated with Auriculas, used to tell me he had many wasteful customers who every spring would write for a relay of large plants, much as they might order spring bulbs from their seedsmen. They kept Scotland going as we kept Holland, for Lightbody who grew his own plants mostly in long-legged garden frames would have been again and again exhausted but for being able to fall back on large collections in different parts of the country. The Auricula is no such forgiving plant as the docile Hyacinth, that in return for having its heart scooped out like an Apple in the cook's hand, will return a hundred-fold in good for evil, in repaying the unkindest cut of all with a handful of useful offsets. Auriculas grown only for a brief display and left to pine in neglect afterwards, are not in the hands of men worth the name of florist.

I have spoken of the Auricula in Lancashire, for that is such a representative county in the history of the flower; but fifty years ago we find by old records that almost every district in Yorkshire, Staffordshire, Cheshire, as well as Lancashire had a circle of Auricula growers. So, too, had many other counties. In Cambridgeshire lived Richard Headly, a renowned florist, and the raiser of one of our best Auriculas—George Lightbody. There were also shows and societies in the home counties, and many growers about London, where Page's Champion and many other sorts of lesser fame were raised.

But the Auricula is the oldest florist flower in precedence of excellence. There were good Auriculas when there were no Roses such as there are now; when the Pelargonium was a thin imperfect thing, the Cineraria a star far from her present magnitude; when the Calceolaria had little of that fine inflation in which it now appears—a floral exposition of the ambitious frog, who in the fable perished miserably in the attempt to enlarge himself to something much above his sphere; when Fuchsias were almost as they had been found, and the Gladiolus was yet but a botanical curiosity.

I am indebted to the researches of one of our oldest florists, Mr. John Slater, for some interesting information about the earliest edged Auriculas. He has spent a long life in the very centre of Auricula culture, acquainted with many a grower and even raiser of the old sorts. Where I mention names I must ask you to attach more than a nominal importance to them, in that the Auricula being a derived flower not found anywhere, no vast importations and auction sales of it are possible. Names have therefore here the weight of species. The raiser is the introducer, and his little garden is a native country. The very names are largely suggestive of the estimation and good report in which the flowers were held by their raisers. Hence they are expressive of greatness and supremacy; and we have—*e.g.*, Champion, Hero, Conqueror of Europe, Rule All, Revenge, Bang Up, Glory, Incomparable, Freedom, Emperor, Ringleader, Complete, True Blue, and so forth.

Very many of the old florists were also Gooseberry growers; and here, too, are names of like great import—Conquering Hero, Overall, Leader, Thumper, Crown Bob, London, Wonderful, and, not last, Roaring Lion. No one had the diffidence to name his new pet berry Second Fiddle or Knock Under; and if he were a bird-fancier he did not select Tomtit or Humming Bird, but chose him Ostrich, Eagle, or Peacock. It is quite time that our newspaper press, from the large dailies to the small provincial weeklies, had their seeming ignorance of what the big Gooseberry really is revealed to themselves. It might be that no dish of the genuine berry had ever smiled on those editorial tables, or we should not have the big Gooseberry a gibe and synonym for that which is vapid and inflated. From the florist, however, has spread the desire for great names to the producers of excelling fruits and vegetables, and is now indulged in alike by the knights of Flora and Pomona, and of the presiding deity of the kitchen garden, Chloris the Goddess of Greens.

(To be continued.)

#### FRUIT-GROWING FOR MARKET.

LIKE music, fruit-growing hath charms, not only to the longing amateur, but to the old practitioner whose years of abundance have been sufficiently numerous to enable him to say that the pleasures of hope are not always delusive in connection with it. Yet even he owns with a sigh of regret how often the promise of his teeming trees has been blighted by ungenial spring weather—so often, that had he depended upon some kinds of fruit for the means of subsistence he would long ago have been ruined. When, therefore, the culture of fruit for market is entered upon in good earnest every sort of fruit that is likely to answer should have a trial. Apples, Pears, Plums, Cherries, are justly accorded a leading position; but what would the fruit-grower do when the blossom of his trees is destroyed by frost and cold wind, if he could not

turn to Strawberries, Raspberries, Gooseberries, and Currants, to all of which a fair proportion of his land is wisely devoted?

Eleven years ago in the pages of the *Journal*, vol. xix., page 97, attention was called to the fact that Black Currants under high cultivation were extremely profitable. The annual crop of some forty fine bushes was shown to be four gallons each, worth 1s. 4d. per gallon, and it was computed that an acre of such bushes would yield in a single year the astounding sum of £322 13s. 4d. The calculation was as worthy of attention then as it is now, for it was based upon the produce of bushes that I had known and watched for many years. It may be said that its more general culture upon an extensive scale would reduce the price of the fruit; so it might, and yet allow a very handsome margin of profit. Bring down the price to a penny a quart, and you still have a total of £80 an acre. So, too, with other bush fruits. I once knew a farmer who had a long steep bank of capital loam overlaying a bed of limestone, unavailable for ordinary crops, which he planted with Warrington Gooseberry bushes that proved very profitable. Raspberries and Strawberries, too, always give abundant crops under good culture, and with both it may be asserted that within certain limits the higher the culture the finer and more abundant the crop. I may well be positive in this matter, for I have had to bring a barren soil into a suitable condition for the growth of all kinds of fruit. Another great advantage belonging to the culture of Strawberries and bush fruits is, that whenever a superabundant crop glut the market, part of the supply can always be diverted advantageously to the fruit preserves. What is known as "people's jam," is frequently, I fear, an unwholesome compound that would be driven out of the market by an increasing supply of really good fruit.

However hard times may be it is unlikely that an ordinary farmer will ever turn his attention seriously to fruit culture. He is not wont to adopt new ideas readily, and the result of his planting fruit trees is apt to be of a very speculative character indeed. With him it is literally a "sticking in" process. A hole is dug, the roots crammed into it, the soil thrown back and trampled down, perchance a few bushes are bound round the stem to keep off sheep and cattle, and the tree is left to its fate. I could point to many a man clever enough in all the ordinary duties of a farm, yet who is quite ignorant of the simple operation of tree-planting. It is a mystery past his comprehension why the young trees planted in the vacant spaces of his old orchard make such slow progress; why trees that have been there for five or six years are very little larger than when first planted. It is undoubtedly true that there are farmers who are perfectly familiar with all the branches of hardy fruit culture; but then they are to the manner born, and fruit-growing has always been part and parcel of their calling. Apart from such considerations tenant farmers require prompt annual returns for the capital which they invest in their holdings. But too few can muster the traditional £10 per acre of capital at the outset, and those who can would regard fruit trees as a very questionable investment. Freeholders having good soil and a favourable situation are the men to take up this matter. If they do it thoroughly, in the way Mr. Roger Leigh is doing at Barham Court, as was explained in the *Journal* a short time ago, they will succeed in getting a better interest for their capital than can ever be had from corn-growing.—EDWARD LUCKHURST.

#### NOTES FROM MY GARDEN IN 1880.

##### GREENHOUSE.

It may perhaps occur to many persons that there is little to be said from year to year concerning a greenhouse that is only some 20 feet long with its annexe of about 12 more, and indeed I have seen some remarks on it as if I were making mountains out of molehills and converting all my poor little ducks into swans; but as I know from many kind letters which I have received that many who are similarly situated to myself have derived both encouragement and instruction from my annual records I shall again notice it, and the rather because I am enabled to have some new features from year to year.

It was with much regret that I parted with the Camellias which have so many years afforded me so much gratification, but "necessity has no law;" and as they were reaching up to the top of the house, both taking up room and being too high up for their flowers to be seen, I was constrained to dispose of them. This I did on terms satisfactory to myself and to the purchasers, and I supplied their place with some excellent small plants about 3 feet high. Some of the varieties I could not replace; and the fine plant of Sarah Frost, connected as it was with sunny memories of Angers, I especially regretted to lose. Each year convinces me more and more that for those who have only a few plants it is much better to keep them indoors altogether than to put them

out, as so many do, in the summer months. The shade of Vines is just the place for them. Cyleamens are invaluable plants; they come in so early and continue so long in bloom, are so bright and clear, that there is nothing in the way of early flowers to compare with them. As I cannot venture on everything I have preferred them to the Chinese Primulas, more especially as the latter are of very little use for cutting, whereas the Cyclamen is one of the most useful plants we can have. I saved a good quantity of seed from the best varieties, and have quite a number of seedlings, which I hope will take the place of the older plants, which after a few years seem to wear out. As with the Camellias, so some of my Azaleas had grown beyond my means of housing them. These also I disposed of, and replaced them with young plants of some of the more recent introductions from Belgium. Of these I had amongst others Charles Leirens, a dark salmon; Apollo, a splendid large white; Madame de Grevé, deep rose edged with white; Imbricata, a very curious Balsam-like flower, but unfortunately the plant seems to be not so good a grower as some of the others; but in size, freedom of bloom, and brilliancy of colour these modest Belgian varieties are far in advance of either the older foreign or English ones.

I had some new Show Pelargoniums from Slough. It may be difficult to see the advance that is made, but on looking back to those of a few years since the increase in size and excellency of form, and now and then a new break in colour, is at once recognisable. Two of these have a melancholy interest—Amethyst and Bridal, raised by the late Rev. T. Brébaut of Guernsey, or rather by his wife, who died but a short time before him. He wrote to me a couple of years ago telling me of her success in raising these varieties, and the severe wrench that her death made so depressed him that his own soon followed. Amethyst is a beautiful rich purple flower with deep maroon top petals. Bridal is pure white without any spot whatever, very free, and with slightly scented foliage. Douglas (Matthews) is rich crimson; lower petals dark glossy maroon; top petals, white centre; fine shape and substance. Goliath (Foster), crimson, with purple maroon spots on top petals; clear light centre. Invincible (Foster), rich crimson top petals, lighter centre; free, dwarf habit. Magician (Foster), top petals dark maroon with crimson margin; lower petals rosy crimson, white centre. Queen of Scots (Foster), top petals orange with rose edge; lower petals rose, white centre. Valiant (Foster), crimson, with dark maroon top petals, shaded crimson, and rose edge. Sensation (Foster), top petals black maroon with crimson margin; lower petals bright rose. Mr. Foster of Clewer still keeps at the head of all raisers of this very beautiful but comparatively speaking neglected class of flowers. There is no class of flowers so satisfactory for winter blooming as the Zonal Pelargonium and its hybrids, for there is now such an intermixture of the Nosegay blood that it is hard to tell them. The various shades of colours are so beautiful—scarlets, crimsons, pinks, white, salmon—that even when you get a bloom here and there on a plant it tends to enliven the house wonderfully. I have grown many varieties, most of which are so fine as to make us wonder where the improvement is to come from. I never keep up the temperature of my house to any particular point, my sole object being to exclude frost, but yet this gives me quite a bright display of flowers.

Of miscellaneous plants I may say that I have found the *Libonia floribunda* most useful, giving bright colour to the house and useful for cutting, although it has the bad property of soon fading. *Primula cortusoides amoena* and *Primula pulcherrima* have also been of great use; while the *Lachenalias*, both pendula (which is early) and tricolor, are excessively gay and do famously for cutting. I am, perhaps, prouder of a fine pan of *Disa grandiflora*, the only greenhouse Orchid I possess, than of any other plant in it. It is this year throwing up, I hope, several blooms and looks very strong. I keep it close to the door and a syringe near to it, and every time I go into the house give it a sprinkle. It is planted in a shallow pan about 8 inches deep in some good peat and sand, and nothing could be more satisfactory than its progress. The plant does not require rest. As soon as the bloom is over I repot it: the young shoots for the following year will then have pushed through the soil at the base of the old, and it is ready to commence again. *Francoa ramosa* I have also found a most useful plant for cutting from; its graceful sprays of white flowers are very charming in a tall vase. *Ixias* I did not succeed with, as I depended on my own bulbs, and experience has taught me that this is a broken reed to depend upon. Like the Hyacinth, it almost seems as if we must look to imported bulbs for good blooms.

Later on in the season Fuchsias, Lilies, and other plants kept up a succession of bloom; and during the earlier months of the year, when flowers are the more valuable, I was always able to cut

a sufficient number to fill a centre vase and stand for the dinner table, and also to have sufficient Camellia blooms for four specimen glasses for the drawing-room. These are now filled with Azaleas, which will probably last until the Tea Roses from the wall gladden our eyes, as it is to be hoped this bitter east wind, which keeps everything back, will not always continue.

Now, I do not lay claim to anything of superior cultivation, but simply to this, that by a judicious selection of plants to be grown and by a certain amount of care bestowed upon them I am enabled to have a great deal of pleasure out of a very limited space, and thereby to offer some encouragement to those who are similarly situated, and who are often dispirited because the directions given for culture and the plans to be adopted involve a much greater expenditure of money and a larger amount of space than they have at their command.—D., *Deal*.

### BIRMINGHAM SPRING SHOW SOCIETY.

APRIL 18TH AND 19TH.

THE first Exhibition of spring flowers held by this Society took place on Monday and Tuesday last in the Town Hall, Birmingham, the satisfactory results achieved auguring well for the future excellency of what is likely to be an annual Show of considerable interest. The weather, that most important factor in the success of floral exhibitions, proved all that could be desired, the first day being particularly fine, encouraging intending competitors to bring their productions and the public to visit them. Although some of the prizes were not very keenly contested for, the exhibits on the whole were of good quality, freshness and vigour characterising the majority of plants staged, while plants were abundant and diversified. They were all shown to excellent advantage by the taste exercised in the general arrangement, which was creditable alike to the exhibitors and to those entrusted with the management. The bulk of the plants occupied three tables extending the entire length of the Hall; the central one, 14 or 15 feet broad, bearing the stove and greenhouse plants, several groups and miscellaneous collections; the other two being occupied with Cinerarias, Hyacinths, Tulips, Spiræas, Ferns, and Mr. B. S. Williams' pretty group. In the corners of the Hall were tasteful and bright groups from several local nurserymen, which assisted materially in imparting an agreeable finish to the general pleasing effect.

The classes were in two sections, the first forty-eight being devoted to gentlemen's gardeners and amateurs, while ten were open to all exhibitors. A great variety of plants were provided for; the prizes, though by no means extravagant in value, being in the chief classes at least sufficient to induce interesting, and in a few instances close, competition. In some classes there was room for much improvement, but another year probably these defects will be in a great measure remedied. No doubt if the financial results of the Exhibition prove satisfactory more liberal prizes will be given, stimulating growers and exhibitors to greater efforts, and resulting in the production of a really first-rate spring Show.

**Bulbs.**—Taking the gardeners' and amateurs' classes in the order they are enumerated in the schedule, the first demanding notice are those devoted to bulbous plants, of which the Hyacinths were the most numerous. The chief class was for eighteen Hyacinths not less than ten varieties, three collections of average merit being staged. The prizetakers were J. E. Wilson, Esq., Edgbaston (gardener, Mr. W. Jinks), C. E. Matthews, Esq., Edgbaston (gardener, Mr. W. Jones), and J. Jaffray, Esq. (gardener, Mr. F. Denning), in the order named. Three other classes were also devoted to Hyacinths, but the general quality was below the average, several collections appearing to be very much drawn, as though they had been either grown some distance from the glass or crowded by other plants. The spikes, too, were rather weak and the colours dull, but some of these defects were possibly due to its being somewhat late in the season for such plants. Two classes were appropriated to Tulips, but in neither were first-rate collections staged. Mr. W. Jinks had the best six single varieties, and L. Hayman, Esq., Edgbaston (gardener, Mr. G. Newell) held a similar position in the class for six double varieties; the other collections being very irregular, including a few good specimens, and many that were of very inferior quality.

**Miscellaneous.**—Following the classes for bulbs were a number devoted to miscellaneous flowering plants, especially Dielytras, Spiræas, and Deutzias. For two specimen Dielytras Mr. W. Jinks and T. Webley, Esq., Selby Oak (gardener, Mr. W. H. Dyer), were the principal exhibitors, both contributing very well-grown specimens flowering freely. The premier collection of three Deutzias was from Mr. Jinks, the plants being 4 feet in diameter and flowering most profusely; indeed they were some of the finest we have seen this season, although not trained in any shape. Messrs. W. Jones and W. H. Dyer followed with smaller examples of this useful plant. Spiræas were well represented, especially in the first-prize collection of six staged by Mr. Jinks; they were in excellent condition with abundant blooms. T. Chatwin, Esq., Edgbaston (gardener, Mr. C. Lusted), and Mr. Newell securing the other chief prizes with plants but little inferior to those already named. One collection only of Roses in pots was staged—namely, those in the class for three, for which Mr. W. H. Dyer obtained the first prize; they were moderately

healthy but backward, very few of the flowers being expanded. A few good Azaleas were shown, but the majority of the specimens were thin and uneven, though flowers were abundant, large, and brightly coloured. The chief prizetakers were Messrs. W. H. Dyer, W. Jinks, and W. Jones. One large pyramidal specimen of Fielder's White from the first-named was probably the best in the Show; it was about 6 feet in height, well trained, and clothed with blooms from the rim of the pot to the highest branches. Cinerarias were represented by several neat collections, the best being contributed by Mr. W. H. Dyer in the class for six; these were compact, the flowers of moderate size and brightly coloured. The first prize awarded for them was well merited. Messrs. F. Denning and W. Jones secured the remaining prizes both in this class and in that for three plants with specimens a little less compact than Mr. Dyer's.

**Stove and Greenhouse Plants.**—These, though not very numerous, produced a pleasing display on the central table. For six specimens Mr. F. Denning was the most successful exhibitor, as he easily secured the premier award with neat examples of *Diosma capitata*, a good pyramidal Azalea *Iveryana*, and a well-flowered *Rhynchospermum jasminoides*; but the finest specimen of all, both in this and the other collections, was a plant of *Dendrobium nobile* in a 10-inch pot. On a rough estimation there could scarcely have been less than one hundred growths, some of which had over a dozen flowers. Mr. W. Jones was second with smaller specimens, notably a well-flowered *Ixora Williami*. For three stove and greenhouse plants Mr. W. Jinks was first with a tall *Ixora alba*, a large *Tabernaemontana coronaria flore-pleno*, and an example of *Medinilla magnifica* nearly rivalling the *Dendrobium nobile* referred to above; it was in admirable health, and had not less than fifty large pendulous panicles of coral-like flowers.

**Fine-foliage Plants.**—In the class for three plants with ornamental foliage in pots not exceeding 12 inches in diameter, Mr. W. Jinks again obtained the chief position with a fine specimen of *Dracæna Mooreana* 6 feet high, bearing broad deeply coloured leaves; *Croton variegatum* of good colour, and *Dieffenbachia Bausei* with ten vigorous growths and pretty mottled foliage. Mr. W. Jones followed with *Pandanus Veitchii* in satisfactory condition; and among others Mr. W. H. Dyer obtained the third place with small but clean specimens. There was only one entry for three Ferns—viz., those from Mr. W. H. Dyer, comprising *Davallia Mooreana* 5 feet in diameter, with large healthy fronds; *Gleichenia dichotoma*, also fine, 3 feet in diameter; and *G. speluncæ*, smaller but similarly fresh and vigorous. Mr. F. Denning was the only exhibitor of three Palms, securing the premier award for graceful examples of *Kentia Fosteriana*, *Phoenix sylvestris*, and *Latania borbonica*.

**Orchids.**—These were by no means so strongly represented as might have been expected, for only one collection was staged—namely, that from C. Winn, Esq., Selby Oak (gardener, Mr. T. Shields). This, which received the first prize, comprised *Zygopetalum crinitum cæruleum* with two large spikes of its peculiar blue marbled flowers; *Odontoglossum triumphans* with four fine panicles; and *Dendrobium Bensoniæ* in beautiful form with white sepals and petals, and a yellow lip blotched with maroon.

In the open class the display was chiefly confined to Auriculas, those from Mr. Sharp, Perry Barr; Sir Josiah Mason, Erdington; and Messrs. Pope & Sons, King's Norton, being the best, and securing the principal prizes for their owners. Cut flowers were not very abundant, but several of the exhibitors already enumerated contributed stands of blooms, the Orchids from Mr. C. Winn being particularly noticeable.

**Groups.**—Without the groups contributed by the nurserymen the display would have been considerably less effective and interesting. One of the most important and beautiful was that from Mr. B. S. Williams of Upper Holloway, which attracted much attention from the visitors. It contained an assortment of choice Orchids, Palms, Ferns, and many other plants, among which the Cyclamens were particularly noteworthy for the size of their flowers. A handsome specimen of *Oncidium sarcodes* was also observable, with a panicle of richly coloured flowers over 4 feet in length. Plants of Azalea Mrs. Carmichael well indicated the excellent qualities of this variety; and among many other plants in flower comparatively rarely seen were *Rudgea macrophylla* with a dense head of white flowers, and *Toxicophlæa spectabilis*, also bearing white flowers in axillary clusters. Near this group in one corner of the Hall was a very tasteful group from Hans Nicmand, Edgbaston. It had a groundwork of Palms, Tulips, Dielytras, Spiræas, Heliotropes, and Mignonette, among which in raised cork baskets were a few selected Palms and Ferns, imparting a very pleasing effect to the arrangement. Mr. Thomas Hewitt, Solihull, had a corresponding group at the opposite corner of the Hall, consisting chiefly of Pelargoniums and baskets of seedling Auriculas and Primroses. Among the Auriculas a double maroon-coloured variety with large flowers was especially noteworthy. A basket of *Anthurium Schertzerianum* edged with Lilies of the Valley was attractive, the contrast between the scarlet spathes of the Anthurium and the white flowers of the Lilies being very striking. Mr. R. H. Vertegans, Chad Valley Nurseries, Edgbaston, contributed a large group, which occupied one end of the central stage. This was principally composed of Hyacinths, Tulips, Lilies of the Valley, and double Cinerarias, which were gracefully arranged with Variegated Maples, Palms, Ferns, and similar plants. In addition to these there were a group of Pelargoniums from Messrs. Pope

and Son, and collection of flowering plants from Messrs. W. H. Dyer and F. Denning, for the two latter of which prizes were awarded.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 21. NEW SERIES.

EVEN when we are pursuing that system of classifying insects which seems as natural as is possible, we are obliged to put into one and the same group, at times, species which in size, appearance, and habit do not present much resemblance. The *Phytophaga*—last in the division of beetles with four-jointed tarsi, and to which also belong the *Rhynchophora* and the *Longicornes* already noticed—look at first an anomalous group. Certainly the name given them is not specially appropriate. “Plant-devourers” they are, it is true, but so are many other tribes in this order. Comparing them with the preceding group, we perceive that they lack their elegance of form; no wonder, for the *Phytophaga* has usually bulky abdomens, oval, round, or perhaps squared. The antennæ are observably short, and the head, through absence of neck, appears to sink deep into the thorax. Yet there are in this group several beetles that can boast of beauty, several also, it must be owned, that have long been known to be mischief-makers in our gardens. Though the bulk of the species live upon the land, a few are partially aquatic, belonging to the genus *Doracia*. About twenty species have been noted in Britain, the larvæ of which live within the stems of water plants, such as the yellow Water Lily and the Reed Mace. The beetles are to be found running over the leaves of these plants, and they can bear submergence without injury. Moderate in size, mostly under half an inch in length, they, like many of the smaller beetles, display a great variety of colour; even in the same species specimens are found with blue, green, red, and yellow tints mixed with darker shades. These insects would be suitable enough as ornaments for the aquarium if they would thrive in confinement.

The genus *Crioceris* contains three species. One is common—the well-known Asparagus beetle (*C. Asparagi*, fig. 71), a tiny creature often seen in hundreds or in thousands about the plants at the beginning of summer. The head and legs are black, but the thorax is red, and the black of the wing-cases is varied by a red line round the edge and six minute spots of white. Small in size as it is, this beetle if alarmed or angry produces a squeaking sound, which might serve as a test to try whether a person’s sense of hearing is acute or dull. I am inclined to think that some authors have rather exaggerated the amount of harm that is done by the species to Asparagus beds. For one thing, it must be remembered that the plant is not attacked during the period when the shoots are cut for the table, the beetles resorting to it in order to deposit eggs when the foliage is developed and the seeds are forming. These eggs are occasionally discovered, but from their minute size they can seldom be removed. The larvæ, thick and wrinkled grubs of greyish hue, are seldom seen in motion, and they adhere very firmly to the plant by their legs; were it not so they would soon be dislodged as the Asparagus waves to and fro in the summer breezes. Having reached their full size (unless the gardener has cleared them off with the branches they may be infesting) they make tracks for the earth, and there conceal themselves until the warmth of another season summons them forth as lively beetles. The rare *C. merdigera* is of a bright scarlet colour, which rapidly fades when the beetle is dead; this has occurred upon the leaves of Lilies.

The beetles of the genus *Cryptocephalus* we mention briefly, since they seldom occur in or near gardens. Their favourite resorts are woods and patches of dense herbage, where they are difficult to capture, since they drop at the slightest touch, or even at the sound of an approach. Delighting in sunshine, their colours are often bright; and they have this peculiarity, that the head can scarcely be seen from above. The larvæ feed upon leaves, concealing themselves in a slight cell, perhaps to escape the researches of birds.

In the family of the *Halticidæ* are numerous species, small in size, but with powers of destruction that place them amongst the conspicuous enemies of vegetation. The antennæ are inserted between the eyes, and the wing-cases are waved at their edges; the thickened thighs are, however, the most notable characteristic of these beetles, suggestive of an ability in leaping, by the exercise of which some species have obtained their popular name of Turnip-fleas or “Hoppers.” It is ascertained beyond all doubt that the Turnip is resorted to by more than one species, but prominence must be given to that which is called *Haltica* (*Phyllotrita*) *nemorum* (fig. 72), which does damage to the crops every season, and sometimes entirely ruins the first sowing in a locality. This yellow-striped beetle cleverly attacks the Turnip while it is young and tender, for the matured plants seldom exhibit signs of

its presence, though several broods have been observed in the course of the season, and the insect also visits the Mangold Wurtzel, the Beet, and the Radish.

The work of destruction is begun by the beetles, which, when engaged in the business of depositing eggs, nibble the seedlings that have just appeared above ground. According to the observations of M. Le Keux, these eggs are only laid at the rate of one daily by each female beetle, upon the under side of the leaves, and so distributed as not to be easily discovered. They are hatched in about a fortnight, and burrow directly into the young leaves, where, indeed, they remain until they have completed their growth. It has been supposed that the larvæ feed externally, but, probably, those that have been detected in the act of crawling upon Turnip leaves were only migrating from an old burrow to a new one, for those who have reared specimens in boxes have found that they will occasionally pass from leaf to leaf. This larva is long and slender, with six short but strong legs. The track it makes within the leaf is little apparent until the creature is out of it and the damage is done. The pupal state is passed in the earth, hence some persons have argued in favour of turning over the ground about that period and burying the surface

Fig. 71.—*Crioceris Asparagi*.

Fig. 72.—*Haltica nemorum*.

soil in which the insect lies, when it is unlikely to be able to extricate itself from the mass of earth.

One of the very small species is *P. Brassicae*, which occurs among the plants from which it has been named, mining the leaves in the manner of *P. nemorum*. This is also deep black, but upon the wing-cases there two streaks of yellow. Mr. Reeks was the first to call attention to the habits of *Haltica fuscicornis*, which in some neighbourhoods and during seasons that favour its increase destroys the Saintfoin while young and various leguminous plants. This species has brownish antennæ; the head, thorax, and legs are red, and the eyes black; the wing-cases are metallic green, highly polished. Spring is the season for the beetles, and the larvæ feed during May and June; but it is one of those species that is unfavourably influenced by heavy rains. During the summer of 1871 it was reported in some journals that this *Haltica* appeared about Hampshire as a destroyer of the mixed growth that is to be seen in the ordinary cottage garden, but there is here, we presume, an error or exaggeration. Insects of this family do not restrict their attacks to the humbler species of the vegetable kingdom. A species of *Galeruca* has occurred upon the Elm, the larvæ feeding in companies and laying bare the lower branches. *H. oleracea* has been long known as an enemy of the Vine in warm countries, both beetles and larvæ being injurious to the leaves. Britain as yet has had, fortunately, small cause of complaint, perhaps owing to our changeful climate.—J. R. S. C.

**HARBINGERS OF SPRING.**—In these scientific days we have daily forecasts of the weather which may be expected within the next twenty-four hours, but how small is the percentage of correct forewarnings! From my observation I am led to believe that some birds must know more of this subject than we do, for I have noticed that Starlings or “Shepsters,” as they are locally called in some parts, will not commence building their nests nor taking possession of their old habitations until mild spring weather has fairly set in. They come at intervals in February and March just to have a peep at their old haunts, whistle to each other from the chimney tops, perhaps stop a day or so, but go away again evidently convinced that it is too soon. This year they paid a

very early but short visit and went away. I heard and saw two or three "prospecting" about my chimney-tops, but they did not like the harsh east wind and the look of the trees covered with snow. When they return and settle down to their business in life I shall think it the right time to put in seeds in the open ground, and not before that time. I remember when we had a mild winter the Starlings came, built and fed their youngsters with what they could get, and culled my Crocuses as salad. This year the Crocuses will escape that. A Swallow has been seen here, and I see that the Wryneck has also appeared as a precursor of the Cuckoo. An old man near me says:—"I reckon they've had a bad winter where they've been, and they want to see if they can't better themselves by coming here." There is a good deal of fact in his remark; the want of food "compels" many, if not all, birds to migrate.—G. O. S., *Lancashire*.

#### THE CRYSTAL PALACE.

AMONG the numerous and varied attractions offered to the public by the Manager of the Crystal Palace Company, there is one that deserves a line of acknowledgment in the columns of the *Journal of Horticulture*. In the central transept there is a huge stage protected by an awning, upon which is the finest and most varied collection of spring flowers in pots that I ever saw. In the top rank are Palms and Tree Ferns, then Azaleas, Cytisuses; next a grand collection of Tulips, Hyacinths, Daffodils, Narcissi, and the front rank is filled with Begonias, Funkias, and other foliage plants. The display of colour is really most attractive, and I would recommend any of your readers who want to see a beautiful sight to journey down to Sydenham one day this week. The small tropical department is now very pretty. The Tree Ferns round the fountain are very fine, and the other plants are skilfully arranged; in fact the whole of the floral arrangements indoors are very good.

Out of doors there is not at present much to interest the gardener, but there are several beds near the rosery which are full of bulbs, and which before these lines are in print will be in full beauty. Wallflowers are also much used, particularly the dark-coloured varieties, and the Golden Feather Feverfew marks out the patterns. Many kinds of bulbs are employed, and with the purple Aubrietia and white Arabis make very pretty beds. The few Roses that I have known for fifteen years are terribly cut, in fact half killed by the frost. The rosery, indeed, exists but in name, and Mr. Head would do well indeed if he could induce the Directors to spend a little money there. The huge panorama of the siege of Paris is nearly ready, and as the visitors to it must pass through the garden, and those who come from the station by way of the rosery, the latter will be much observed, and its forlorn condition much commented upon. A school of floriculture is to be commenced on the 1st of May, and if Roses and florists' flowers continue to be neglected I cannot see how the students can learn their business properly.—WYLD SAVAGE.

#### ROSES ON THEIR OWN ROOTS.

VERY few, I should imagine, of the constant readers of the *Journal of Horticulture* would think of doubting assertions made by Mr. Taylor. At the same time to see is to be convinced; and could others visit Longleat and judge for themselves, as I recently have done, what the Rose on its own roots is capable of doing, there would soon be a change in the general practice. The splendid plants of Teas and Hybrid Perpetuals, both in pots and the open ground as grown there, compare most favourably with those specimens of the same varieties on either dwarf or tall stocks usually seen in other gardens. Many of the two-year-old specimens of the three varieties of Teas alluded to on page 208—viz., *Souvenir d'un Ami*, *Catherine Mermet*, and *Devoniensis* in 12-inch pots, were 6 feet in height and remarkably healthy; they had been flowering nearly all the winter and still had good blooms. Those in the open, and which I trust to see when at their best, may be likened to a strong stool of Manetti which the grower has inadvertently continued pruning year after year. In other words they are great bushes with medium-sized healthy growth apparently quite uninjured by frost. Mr. Taylor may well declaim against the "mop-headed parasites."—VISITOR.

HEBECLINUM OR CONOCLINUM IANTHINUM.—Some years ago this plant was considered worthy of being exhibited in a collection of flowering stove plants, but, like many more, it has been cast aside for some that are less worthy. It succeeds best in an intermediate house, but flowers a month later than in a stove. It produces its large tufts of lavender-coloured flowers in great pro-

fusion, and when shaded from the direct rays of the sun continues in bloom a considerable time. When not in flower the foliage is very ornamental. Small plants grown in 6-inch pots produce fine heads of bloom and are useful for decorating purposes. It is a good plan to set the plants outside in the summer months to have the wood well ripened.—STIFFORD.

#### HIBBERTIAS.

CLIMBING plants which possess either attractive foliage or flowers are both useful and ornamental in stoves, greenhouses, and similar structures, where the chief object is to produce a satisfactory display with as much economy of space as possible. The rafters of span-roofed houses and the back walls of lean-to's can always be profitably covered with such plants, as they not only add to the general effect but often afford a very acceptable supply of flowers with comparatively little trouble. In the greenhouse and conservatory particularly the appearance would be very unsatisfactory without climbing plants to remove the formality of bare roofs and walls, the results being pleasing in proportion to the taste exercised in the selection and arrangement of the plants employed for that purpose. Diversity in the colours and forms of the flowers and some variations in the habit are

Fig. 73.—*Hibbertia dentata*.

the principal points requiring attention, and there are now so many suitable plants grown that it is not difficult to obtain a good collection combining all the desired qualities. One of numerous genera containing climbing species adapted for growing in cool houses is that under consideration, of which at least one form is generally well known, some of the others being occasionally seen in moderately large collections. The Hibbertias cannot rank among the most useful plants as the flowers are somewhat fugacious, but as these are very freely and successively produced a bright display is maintained for a much longer period than might be expected from the short duration of the individual flowers. The species present more diversity in habit and foliage than in their flowers, for the latter vary chiefly in size, the colour being uniformly light or dark shades of yellow—tints which are common in flowering plants, but in the case of the Hibbertias the contrast with the bright green leaves is rather pleasing.

The cultural requirements of these plants are not very numerous. A soil composed of good turfy loam not too heavy, with a fair proportion of sand, suits the more vigorous species, which are usually planted out in greenhouses and then trained to the roof or wall. A little attention is needed in pruning, removing the straggling or weak shoots and keeping the plant from insects, mealy bug being in my experience their chief enemy. For the dwarf or shrubby species which are grown in pots a little peat may be added to the compost, also providing thorough drainage, as they dislike any approach to a stagnant condition of the soil. With attention to these few particulars little difficulty will be experienced in the culture of Hibbertias, the chief of which are indicated in the following notes.

*Hibbertia volubilis*.—This, the longest introduced and best known member of the genus, is distinguished by its vigorous habit and large rather fetid flowers. The leaves are lanceolate in form, 3 or 4 inches long,  $1\frac{1}{2}$  to 2 inches broad, and dark green, the flowers being bright yellow with spreading petals, and are produced during the early summer months. Seeds were first imported about 1790, and in the two or three following years plants were raised in several collections near the metropolis and were thence gradually distributed. The plant was originally known as a *Dillenia*, but subsequently a new genus was constituted in honour of George Hibbert, Esq., of Clapham Common, a gentleman distinguished for his love of plants, who is said to have employed a collector at the Cape of Good Hope for some time at his own expense. In describing the plant under its new name, Andrews referred to Mr. Hibbert as one "whose knowledge and fervour in botanical pursuits, as well as liberality in his endeavours to enrich our collections from every quarter of the globe, but especially from the Cape of Good Hope, has not been exceeded by any, and we are well assured no name deserves a place on botanical record more than that of Hibbert."

*H. dentata*.—Like the last, this also has been known some time, having been first introduced at the early part of the present century, and it is now probably nearly as common as *H. volubilis*. It is not quite so strong-growing as that species, and has smaller flowers and leaves, but it is very neat and pretty, and does not possess such an unpleasant odour. The leaves are very dark green, frequently with a brownish tinge, which has a peculiar appearance. The flowers are dark yellow, about  $1\frac{1}{2}$  or 2 inches in diameter, and are produced singly in the axils of the leaves. The woodcut on page 312 represents a small flowering spray, and well indicates the principal characters.

*H. Rheedi*.—One of the dwarfier species but very pretty, and apparently greatly neglected, for it is rarely seen in cultivation. It is well suited for growing in a pot, and with a little attention in training an elegant specimen may be obtained, such as that which is frequently seen in the winning collections of stove and greenhouse plants exhibited at the Royal Botanic Society's Spring Shows by Mr. G. Wheeler, gardener to Lady L. Goldsmid, Regent's Park. This specimen is invariably admired owing to the profusion of small bright yellow flowers which clothe the slender branches, and of which some idea can be formed from the annexed engraving (fig. 74), representing a spray kindly forwarded by Mr. G. Wheeler. Referring to a plant presented by Messrs. Veitch, which is now flowering in the Cambridge Botanic Garden, my esteemed friend Mr. R. J. Lynch sends the following brief descriptive note—"Hibbertia Rheedi is an extremely charming plant. It has not the large flowers of its better known congener, *H. volubilis*, but a multitude of small ones. They are studded thickly over the plant, which is of wiry and much-branching habit, and bears numerous linear leaves. It is somewhat rare, but deserves to be better known." I have no certain information as to the origin of this plant, but in the "Gardeners' Year Book" of 1871 it is described under the name of *H. stricta*, being said to be from Australia, and Mr. Gower of Tooting thinks "it came from seeds of Müller's distribution." Perhaps some other readers of the Journal can give further particulars concerning its history. The name is sometimes spelled *H. Reedi* or *Reidi*.

Other but little known species are *H. grossulariaefolia*, of trailing habit, with leaves resembling those of the Gooseberry in form; *H. perfoliata*, with flowers like *H. dentata*, but distinguished by the base of the leaves surrounding the stems; *H. Cunninghami*, an elegant and distinct species, with linear leaves 2 to 3 inches long; and *H. pedunculata* or *corifolia*, which resembles *H. Rheedi* in general appearance but is more lax in growth. All these are well worth attention, but are difficult to obtain.—L. CASTLE.

#### APRIL SHOWERS.

AFTER a long continuance of dry weather, accompanied by east winds of more than usual keenness and severity, a most welcome

change to a warmer temperature and genial showers has been gradually setting in since the 9th inst. Up to the 11th, when the first heavy showers of rain fell, things look blacker and barer than I ever remember to have observed at the same date. Fruit trees are remarkably backward, Apricots showing bud and bloom very shyly and irregularly, Pears rather more forward comparatively and fuller.

As to Roses, many standards look in a precarious condition, and I fear by some accident my trees were pruned too early, so that the frosts had too much opportunity of injuring them. As yet most of my small collection of Teas look fairly, some even quite promising, specially Reine Marie Henriette, which has been in full leaf for a fortnight. It is only a small plant put in last autumn together with Climbing Devonensis, also healthy-looking, and trained to a south-west wall. Besides mulching, these plants were well screened by Yew boughs.

Fig. 74.—Hibbertia Rheedi.

Amongst other surviving Tea Roses are Rêve d'Or, Madame Falcot, Marie Van Houtte, Triomphe de Rennes, Madame Willermoz, Souvenir d'un Ami, Innocente Pirola, Cheshunt Hybrid. Dwarf Hybrid Perpetual Roses on the Manetti stock almost without exception look well hitherto. I experimented with a few of those, pegging them down last autumn. The earth would appear to be kinder than the air, the pegged-down shoots being markedly more forward and vigorous than the rest of the tree. Most of the dwarfs were pruned about the last days of March, those planted last autumn a few days later.—A. M. B., *Mid-Lincoln*.

A NEW AUSTRALIAN FRUIT.—An interesting journal from a prospecting gold-mining party has lately appeared in the *Queensland Courier*. The scene is on the head waters of the Daintree river, whose lower scrubs are so famous for the rich soil being taken up for Sugarcane. Among the slate and granite ranges of the upper Daintree this new sort of native fruit was discovered. Mr. Palmerston thus describes it—"There is a large fruit here which grows on a very tall tree. When green it is much the shape

of a large Apple; when ripe the skin is black, and the inside of a deep red, with three or four large seeds in it. This fruit is of a soft nature something like the Plum, and stains anything it comes in contact with yellow. The taste is the same as a Lemon, and from it, so pulpy is the fruit, a bucket of jam could be got in a few hours. It eats very nicely with sugar. We used a great deal of it, as we had no beef." What with an immense area of rich pastoral land, a coast rapidly being taken up for sugar and spices; mountains bearing gold, silver, and tin; seas with pearls and bêche de mer; and forests of edible fruit, North Queensland is determined to be noticed.

#### TALL VERSUS DWARF KIDNEY BEANS.

AS many of your readers will now be thinking of sowing their Kidney Bean seed, the present will be a good time to call attention to the merits of tall and dwarf varieties. As a rule tall or runner Beans are the greatest favourites, and they are the most grown; but I will not say they are the most useful in all cases, or indeed in the majority of instances, as I think many attempt to grow tall Beans when dwarf varieties would answer their purposes much better in every way. This would be particularly the case in small gardens, or in all gardens near towns where stakes are difficult to procure, and where from the frequent absence of these the runner Bean crop is not so satisfactory as it otherwise would be. Tall Beans are not such a sure crop as the dwarfs. In 1878-9 we almost failed to obtain as much from them as would pay for the seed, and certainly they did not pay for other labour. Their growth was rampant, but the pods were small and few; yet the dwarfs produced a full crop as usual. This was satisfactory, and argued well for their extended use, and there are other matters connected with them that will do the same.

Supposing a sowing of each kind were made on the same day, the dwarf Beans would be ready for use many days or perhaps weeks before the tall ones. Then, again, tall Beans occupy much space. Only one row can be had in a space from 4 to 6 feet wide, and for about as much as this on each side no useful crop can be raised under the shade of the Beans. According to this one row of tall Beans may be said to occupy a strip of nearly 12 feet wide, in which space six good rows of dwarfs might easily be grown, and would probably give more produce than one row of tall Beans. It must be remembered that dwarf Beans are not like dwarf Peas. The latter come all into bearing together, and little more than one good picking can be had from them; but dwarf Beans give a long succession, and blooms open and form pods long after the first have been gathered. Dwarf Beans require no stakes, and from their habit they are not half so liable to be injured by either frost or wind as the Runners. Osborns' Forcing is our favourite for first crop, Canadian Wonder is the next, Osborns' is the best early and the best late, and Canadian is good in midseason.

The first sowing may be made in a warm part of the garden and on the driest piece of soil from the middle to the end of April. From this sowings may be made every three weeks or so on until the first week in August. Rich soil suits them best, and the seed should not be more than 2 inches below the surface. Never allow the pods to become too old for use at the outset, as this will check after-production.—PRACTITIONER.

THE number of people registered as entering the ROYAL HORTICULTURAL SOCIETY'S GARDENS at South Kensington on Monday last (Bank Holiday) was 12,246—an increase of two thousand on the number admitted on the corresponding day of last year. The entrance fee was 2d. each person.

— "G. O. S." writes—"Have any of your readers ever noticed that the THORNS OF SOME ROSE TREES are more poisonous than others? I think that it is so, and that of all Maréchal Niel is the most poisonous. My gardener says that it has worse claws than a cat! and for myself I can say that when I have had one of its thorns in my finger the stinging pain has

lasted longer than from any other Rose thorn; indeed I now write suffering from a puncture, and not a deep one, from a Maréchal Niel thorn under my first finger nail five days ago."

— THE second portion of MR. DAY'S ORCHIDS was sold by Mr. J. C. Stevens at his auction-rooms, Covent Garden, on the 12th and 13th inst., the total amount realised being £1803 7s. 6d. The following were the prices obtained for the principal specimens—A fine plant and beautiful variety of *Cattleya exoniensis*, forty-eight guineas; an autumn-flowering variety of *Cattleya labiata*, twenty-two; a large specimen of *Cattleya Skinneri* with twenty-two growths, twenty; *Saccolabium præmorsum*, ten; *Lælia anceps rosea*, twenty-two guineas. A good specimen and fine variety of *Aerides affine*, twenty-seven guineas; *Angræcum Chailluanum*, fifteen guineas; *Phalænopsis intermedia*, sixty-two guineas; and a smaller plant, forty-four guineas. *Saccolabium guttatum*, very fine plant, twenty-two guineas; *Masdevallia ignea aurantiaca*, twenty guineas; *Lælia elegans* var. *Wolstenholmæ*, eighteen guineas; *Dendrobium Schröderi*, thirty-eight guineas; *Lælia purpurata*, thirty guineas; and *Cypripedium Spicerianum*, twenty-five guineas.

— UNDER the significant but by no means elegant title of "Dish Rag," a correspondent of the "American Floral Cabinet" refers to the Egyptian Loofah, or *LUFFA ÆGYPTIACA*, a member of the Cucumber family. The internal portion of the fruit is very fibrous, and when the pulp is removed a sponge-like substance remains, which is employed in America for bathing purposes. Specimens suitably dried and prepared may be seen in many London hairdressers' shops under the name of Egyptian Loofahs.

— MR. W. TAYLOR writes—"On the 31st March I cut 860 blooms averaging 3 inches across of BELLE ROSE CARNATION for decoration for a dinner party. A week before three hundred trusses of *Pelargonium Guillon Mangilli* were employed for the same purpose; the last-named were cut from plants in a small house in which Melons are growing. Let me remind your readers once more that this *Pelargonium* is of no use in a cool greenhouse for winter flowering, and that I do not recommend it for outdoors. It likes heat, and then it will produce three times as many flowers as any other *Pelargonium* I know. On some of the trusses there are three dozen fully expanded pips, which are very large. Single *Pelargoniums*, however pretty they may be, are comparatively valueless for cutting because they fall so quickly; double or semi-double ones never fall."

— WITH reference to the article and figure of the fine Everlasting *ASTELMA EXIMIUM* a short time since, I am glad to say that the plant was cultivated by the Messrs. Veitch a few years ago. It is to be hoped they still have it.—L.

— THE same writer remarks—"I know of no plant that produces a more brilliant display of flowers in winter than *TROPÆOLUM BALL OF FIRE*, recently noted in this Journal. It has bloomed continuously in the Cambridge Botanic Garden for the last nine months. During summer a few plants were grown in pots against a south wall, and when frost was expected were removed to a greenhouse. If trained on strings they are easily moved and placed in any required position."

— WRITING respecting *VALERIANA PHU* VAR. *AUREA* "R. J. L." observes—"Notice is now being taken of this plant, and I am surprised from the brilliancy of its effect that it has not become almost universal. It is a perfectly hardy herbaceous plant, and one of the earliest to unfold its leaves. It grows so far in almost any soil, and is easily increased by division. It is far brighter than Golden Feather, but its best effect is for spring gardening, as later on it becomes dull."

— A CORRESPONDENT sends the following note upon *STRELITZIA PARVIFOLIA*:—"This plant, while bearing an inflorescence equal to and almost the same as *S. reginæ*, is remarkable for its tiny leaf blade in comparison with that species. This is a very ornamental genus, and is interesting for the curious extremes of its leaf development. In *S. angusta* the leaf blades are several feet in length, while in *S. juncea*, if we remember rightly, there is no blade at all. The leaf blade of *S. parvifolia* is about  $1\frac{1}{2}$  inch long; in *S. ovata* it is much larger, and in *S. reginæ* it is of still greater size. *S. angusta* is least to be brought into comparison, being a very distinct species with tall stem, but the others are very nearly related. *S. parvifolia* is now attractive in the Cambridge Botanic Garden."

— OF late years the cultivation of LIBERIAN COFFEE (*COFFEA LIBERICA*) has been energetically pushed in English Coffee-growing colonies and possessions. This has been due to two causes:—First, the cultivation of Arabian Coffee (*Coffea arabica*) has been severely crippled in the New World by the "white fly," and in the Old by the "leaf disease" (*Hemileia vastatrix*). Secondly, Liberian Coffee being a more tropical plant, grows well at a zone of altitude below that which Arabian Coffee requires. The produce of the plantations of the new species is now coming into commerce. At present it does not find much favour apparently in England, but in America it is better appreciated. Recent sales at New York of Ceylon-grown Liberian Coffee have realised 93s. per cwt., or 12s. above the current quotation for middling plantation Coffee (Arabian) in the London market. This is a result of great importance for the West Indian Islands. Liberian Coffee has been found in Dominica to possess a comparative immunity from the attacks of the white fly, the ravages of which had all but completely extinguished the Coffee cultivation of the island. Not merely therefore can West Indian Coffee cultivation be revived with reasonable prospect of success, but there is the additional encouragement of a ready market easy of access in the United States.—(*Nature*.)

#### THE NATIONAL AURICULA SHOW (SOUTHERN SECTION).—APRIL 19TH.

ONCE again the great alpine tournament has been held, and the day could not have been much less keen than the progenitors of the flowers must often have experienced on the mountains of Switzerland, for a biting easterly wind prevailed, which was the more felt since it followed several days of genial weather. Those days have had a wonderful effect on vegetation generally, and have been undoubtedly of great benefit to the flowers exhibited at the Show under notice. Had there been no favourable break in the prolonged cold of March and early April it would have been well nigh impossible for northern growers to have exhibited on the 19th; and as it was they have only been able to do so by more forcing than the Auricula likes, and which weakens the flower stems and flowers, and deprives the colours of their gloss and freshness; and not only are the Auriculas that are exhibited impaired by too much forcing, but unfortunately those left behind, hundreds of cherished plants, are in a corresponding degree weakened. Those, therefore, who make these efforts and incur the risks in the public interest—for the fame of the chief contributors is established—deserve a large meed of public approbation. Unquestionably the southern growers had the advantage this year, but they were not allowed to have all the honours of the day, as will be seen by the awards. The Show was perhaps not quite so large as that of last year, but it was better. The plants were generally dwarfer, and fewer sticks were employed; and if all the flowers on the trusses were not fully expanded the majority of those that were open were very fine, and the freshness of youth pervaded the Show.

In the class for twelve distinct varieties the prizes were awarded in the same order as last year—namely, Rev. F. D. Horner, Kirkby Malzeard, Ripon, first; Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, second; and Mr. B. Simonite, Rough Bank, Sheffield, third. Mr. Horner's collection contained such nearly new and beautiful varieties as the exhibition selfs Ringdove and Heroine, which will bear his name to posterity; Simonite's Frank Simonite (very fine), Horner's Ajax, Walker's J. Simonite, &c., with some seedlings,

including Snowdrift (white-edged), which is referred to below Intrepid, and Erebus, a fine dark self. Mr. Douglas's plants were larger—indeed he grows Auriculas stronger than any other exhibitor, and thus, while he loses a little in the refinement of the flowers, does not lose many prizes, which after all is the real test of cultural skill. His plants and flowers were very fine, and included excellent examples of George Lightbody, Heap's Smiling Beauty, Colonel Champneys, Lancashire Hero, Campbell's Pizarro, Douglas's Silvia, Taylor's Glory, Douglas's Hilda, Read's Acme, and a seedling named Mabel, which obtained the premier prize as the best Auricula selected from the whole Exhibition. It closely resembles George Lightbody, was very fresh, bright, and well formed. It deserved its position. Conspicuous in Mr. Simonite's collection was his grand self Mrs. Dodwell, which ought to be grown by the dozen for conservatory decoration; a charming example of Ringdove, Booth's Freedom, Richard Dean, and Frank Simonite were also good, but the majority required another week at least to bring them into the cultivator's usual exhibition form. J. T. D. Llewelyn, Esq., Penllergare, had the fourth prize with small plants and large flowers of excellent colour. It is a little surprising how this exhibitor contrives to produce such fine flowers from plants so small.

In Class B, for six plants, dissimilar, the Rev. F. D. Horner was again placed first with six regular plants of Horner's Ajax, Lancashire Hero, Horner's Sapphire, Campbell's Pizarro, Horner's Phantom, and Simonite's Frank Simonite. Mr. Douglas was second, his notable plants being Simonite's Frank Simonite, Trail's Prince of Greens, Lancashire's Lancashire Hero, and Headly's George Lightbody; S. Barlow, Esq., Stakehill House, Castleton, Manchester, third, exhibiting Horner's Ringdove, Lee's C. R. Taylor, Simonite's Frank Simonite, Oliver's Lovely Ann, Campbell's Pizarro, and Sam Barlow in good condition. R. K. Penson, Esq., Denham House, Ludlow, was placed fourth, and J. T. D. Llewelyn, Esq., fifth with highly creditable examples.

Five competitors staged in Class C, for four plants, dissimilar. Mr. R. K. Penson secured the first prize with a fine and bright collection, both the paste and colours being very fresh and clear; a fine truss of Turner's Vulcan bearing eleven good pips was very conspicuous. His other varieties were True Briton, George Lightbody, and Col. Taylor. These plants were altogether excellent, and the exhibitor deserved the honour he won so well—we had almost said easily—which is no small achievement when we consider to whom the remaining prizes in the class went. Mr. Douglas was awarded the second prize with Turner's Chas. Perry, Headly's George Lightbody, Taylor's Glory, and Leigh's Col. Taylor. The trusses in this collection were bold and erect, but lacked that clearness and brilliancy of the first-prize collection. Mr. B. Simonite was a very good third. This collection contained a magnificent truss of Frank Simonite bearing eleven finely developed pips. S. Barlow, Esq., secured the fourth prize, and J. T. D. Llewelyn, Esq., the fifth. In the class for two plants there were nine contributors, Mr. Douglas being first with Heap's Smiling Beauty and Lancashire's Lancashire Hero; Mr. B. Simonite second with Frank Simonite and Brilliant; Rev. F. D. Horner third with Lancashire Hero and Horner's Ringdove; R. Gorton, Esq., The Woodlands, Golden Brook, Eccles, Manchester, fourth with Robert Trail and C. J. Perry; R. K. Penson, Esq., fifth with Kay's Topsy and Robert Trail; J. E. Hay, Esq., Newcastle-on-Tyne, sixth with a grey-edged seedling and Trail's Beauty.

In the class for a single plant of green-edged the Rev. F. D. Horner was first and eighth with Lancashire Hero. Mr. Penson second and fourth with Prince of Greens and Simonite's Talisman. Mr. S. Barlow was third, Mr. Simonite fifth, and Mr. Douglas sixth and seventh. For grey edges Mr. Penson was first and eighth with George Lightbody and Confidence; while Mr. Douglas secured the other six prizes—viz., second, third, fourth, fifth, sixth, and seventh respectively, with Headly's George Lightbody, Kay's Alex. Meiklejohn, Read's Dr. Horner, and Headly's E. A. Brown. This was a very fine class indeed. For white edges Mr. Douglas was awarded the first, second, third, sixth, seventh, and eighth. With Heap's Smiling Beauty he secured the first, second, sixth, and seventh prizes; Trail's Beauty gained him the third, and Smith's Ann Smith the eighth. Mr. B. Simonite was here placed fourth with Trail's Beauty, and Mr. Penson fifth with True Briton.

In the self class R. Gorton, Esq., secured the first, third, and fourth prizes with Blackbird; the fifth with a seedling. Mr. Penson received the second prize with Lord Lorne; Mr. Bolton, 84, Wilderpool Road, Warrington, was sixth with the same variety; Mr. B. Simonite seventh with Pizarro; and the Rev. F. D. Horner eighth with Horner's Daphne.

In the large class for fifty plants, not less than twenty varieties, to include Alpines, Messrs. Douglas, Turner, and Llewelyn were placed first, second, and third respectively. The collection to which the post of honour was awarded (Mr. Douglas's) was remarkable for their vigour as well as their substance of bloom. Noticeable among other varieties were Spalding's Metropolitan, Douglas's Silvia, Kay's Trophy, Kay's Alexander Meiklejohn, Taylor's Glory, Hepworth's Smiling Beauty, Turner's Charles Perry, Headly's Alderman Wisbey, Trail's Beauty, fine; Lady Sophia Dumaresque, Cunningham's John Waterson, Smith's Lycurgus, as well as some good seedlings. The Slough second-prize plants were beautifully fresh and bright, but fully a week behind the first-prize collection, but they gained in sturdiness what they lacked in size. A dark self, Sims' Vulcan, was

particularly conspicuous; Turner's Charles Perry was very pleasing and prominent; a splendid truss of Simonite's Frank Simonite was magnificent; Turner's Col. Champneys, Clipper, and a few good seedlings were all beautiful. Mr. Llewelyn had Frank Simonite, George Lightbody, and a few others very good, but the generality of the plant were smaller than those of the other competitors.

In the class for twelve Alpine Auriculas, dissimilar, Mr. Turner was placed first with a very fine collection. The whole of the plants with the exception of Gorton's Diadem were of his own raising, including four seedlings unnamed, also Mariner, Unique, Mrs. Llewelyn, Mrs. Thomson, Evening Star, Rembrandt, and Mrs. Dodwell. Mr. Llewelyn was a very good second, and exhibited a very pleasing collection consisting of Dolly Varden, Ovid, Mrs. Meiklejohn, Echo, James Fowle, Percival, Gwendoline, Mrs. Llewelyn, Evening Star, Distinction, Unique, and one or two seedlings. Mr. Douglas was awarded the third prize for a fresh and bright collection. For six dissimilar Alpines Mr. Douglas was deservedly awarded the first prize; his collection was remarkably clean and fresh, with the colours well blended. Turner's George Lightbody, Mrs. Llewelyn, and Queen Victoria, with two or three seedlings of Mr. Douglas's raising, were very noticeable. Mr. Turner obtained the second prize; Marginata and Sensation were particularly fine. Mr. E. Adams, Swalwell, Newcastle-on-Tyne, was placed third; Mr. Llewelyn fourth, and Mr. Barlow fifth, all exhibiting well. For a single specimen Alpine, gold centre, Mr. Douglas was first, third, fourth, fifth, and sixth. First with Gorton's Diadem, third with Col. Scott, fourth with President, fifth with a seedling, and sixth with Gorton's Diadem. Mr. Turner obtained second prize with a seedling. For white or cream-centre Alpines Mr. Turner was first, second, and fourth; Mr. E. Adams third, Mr. Douglas fifth, and the Rev. E. L. Fellowes sixth. Twelve Fancy Auriculas, Mr. S. Barlow secured the first prize and Mr. W. Bolton the second, both exhibiting seedlings which were more curious than beautiful.

Only two certificates were awarded for Auriculas—namely, to Mr. Douglas for *Mabel*, a grey edge which may occasionally come green. It is a very fine flower, with smooth circular paste and a thin line of body colour. It bears somewhat a close resemblance to George Lightbody, but differs from that variety, and especially in the foliage. Also for an unnamed seedling exhibited by Mr. Horner, the parentage of which is George Lightbody and Smiling Beauty. Special prizes were awarded for Auriculas, but as all the cards were not affixed when we left the Exhibition we can only name the following:—To Mr. Horner for a fine dark self, Erebus (first), Intrepid (second), and Snowdrift, white-edged (first); and to Mr. Douglas (first) for *Mabel*. The last-named exhibitor and Mr. Turner has also prizes for some Alpines.

**POLYANTHUSES.**—In the class for six gold-laced varieties S. Barlow, Esq., Stakehill House, Castleton, near Manchester, was first, all the plants being his own seedlings. To *Criterion* a first-class certificate was awarded. It is a circular clearly defined flower, rich in colour and lacing. It was also awarded a first prize as a seedling. *John Bright* had a first-class certificate, and a second prize as a seedling. It is a large and very bright flower, but a little irregular in form. *Firefly*, a sparkling flower with a red ground, was awarded a first prize as a seedling. The others in the group were Sunrise and an unnamed seedling. Mr. Douglas was placed second with the best grown plants that have perhaps ever been exhibited at the Society's southern shows. They included Lancer, Cheshire Favourite, Exile, George IV., President, and Rev. F. D. Horner. Mr. W. Bolton secured the third prize. For three plants the prizes went in the following order to Messrs. Douglas, Bolton, and Barlow. For one plant Mr. Douglas was first with Exile, Mr. Barlow second with George IV., Mr. Cauldwell third with George Buck, Mr. Llewelyn fourth with Lancashire Hero, Mr. Barlow fifth with Sunrise and sixth with Lancashire Hero.

In the class for twelve Fancy Polyanthuses Mr. R. Dean, Ealing, was first, the plants being vigorously grown and in good varied colours. Mr. Hooper, Bath, was an excellent second with dwarf plants and good varieties; Mr. Douglas being third with larger but rather less sturdy examples. Messrs. Dean and Hooper were the only exhibitors in the class for twelve Primroses, the prizes being awarded in the order named. The plants were admirably grown and flowered, and their varied colours from pure white to rich crimson had an excellent effect. For twelve hardy Primulas, distinct, Mr. Douglas was placed first with *P. rosea*, a fine plant; *P. japonica*, *P. intermedia*, *P. Munroi*, *P. marginata*, *P. sikkimensis*, and several forms of *P. amœna*. Mr. S. Barlow was second, his collection including the true Bardsfield Oxlip; Mr. Llewelyn was a very close third. *P. viscosa* was extremely fine; *P. cashmeriana* and *P. verticillata* also showed to great advantage.

**MISCELLANEOUS EXHIBITS.**—These contributed greatly to the effect of the Show. Mr. Turner staged about 100 Auriculas, chiefly Alpines, which were very much admired. Mr. Cannell had a large collection of Auriculas, Alpines predominating, many of which were very singular. He also staged Polyanthuses and Primroses, and a good plant of the fine double *Tropæolum Hermine* Grasshoff. Mr. G. F. Wilson, F.R.S., staged a small group of Primulas, including the rich Bunch Primrose Herman Wilson. Mr. Dean exhibited a group of hardy flowers, amongst which Polyanthus Meteor was extremely telling, the two colours, crimson and gold, being very rich. Messrs. Lane & Son had a very fine group of Rhododendrons in pots admirably flowered, also Roses in similarly good condition. Messrs. Osborn

and Sons a mixed collection of decorative plants, to which Anthuriums and Imantophyllums, good varieties of both, contributed brightness. Mr. Charles Turner staged a collection of Azaleas, half-standard plants in 6 and 7-inch pots, the heads 18 inches in diameter, the varieties and flowers being of the best quality, and the whole highly effective. Messrs. Veitch had a choice group; very fine was *Dendrobium aggregatum majus*, and *Boronia megastigma* imparted perfume to the group. Mr. B. S. Williams contributed a large and excellent group of stove and greenhouse plants; Mr. Aldous, decorative plants; Mr. Barr, Narcissuses, Grape Hyacinths, &c.; Mr. Hooper, Bath, very fine Pansies; and a group of remarkably dwarf, well grown and flowered Cinerarias was sent from the Society's garden at Chiswick.

### NO FLOWERS TO CUT.

"WE have neither a flower to cut, a plant fit to bring in the house, nor a single expanded bloom out of doors, yet we keep a gardener with nothing else to do but grow these things for us. In the cottage gardens are Snowdrops and Crocuses in full bloom, Christmas Roses just going out, and Daffodils and Poet's Narcissus promising an abundant succession; but our poor garden, where we spend at least £100 a year, has at present neither a flower nor the immediate promise of one. True, we have had some Primulas, but they are over, and the Cyclamens, of which I am very fond, did not succeed. John says they had worms at the roots."

Something like this was the lament of the proprietress of a moderate sized garden during the early part of last month, with whom I could but sympathise, and express a wish to find out if possible where the fault was. A hasty look through the garden soon convinced me that the fault was not altogether on John's side. He may have faults, poor man, like other mortals, but laziness certainly is not one of them. I found the vegetable garden in excellent condition for such a season, the lawn and walks in faultless trim, and a mixed greenhouse and vinery full from floor to roof of plants as healthy as we could wish to see, with the single exception of the Cyclamens, the treatment of which apparently had not progressed as in most other places during the last dozen years. But, of course, this was a very small affair, though an unfortunate one, as the proprietress was fond of Cyclamens. However, if I had only one failure in a season I should think myself very fortunate. What, then, was the fundamental error in management? It was simply this—John was concentrating all his energies in the floral department to produce a grand display in the flower beds in summer. The greenhouse contained thousands of bedding Pelargoniums, a score or two of beautiful healthy Fuchsias, three or four Azaleas not yet showing flower, and the usual assortment of odds and ends which every amateur picks up and places between his other plants, leaving them waiting there for a better day which never comes. John may be responsible for this state of things, inasmuch as his "hobbies" may be "bedding-out" and Fuchsias, but certainly the proprietor has an easy remedy in his hands. His beautiful piece of sloping lawn is at present cut-up by several fantastic-shaped beds, and as they, at least for half the year, show only the black bare earth, they would be much better turfed over. Thus far the lady of the house would go with me, but she would like the turf taken away later and the bedding plants placed there. Well, I should like to persuade her to do without the beds near the middle of the beautiful green sward for just one summer, and then I really believe she would have no desire to have them again.

I have nothing whatever to say against masses of colour in their proper places, and I would on no account check John's enthusiasm for Fuchsia growing; but I could say very much against the system which must have a flower bed in every neat piece of lawn. But supposing the bedding arrangement to be all that is right in point of taste so long as it lasts in good condition, is it worth the ten months' labour and self-denial which it costs to produce the two months' display? Remember, this display is at a time when Nature is doing her very best to clothe all around with beauty, and when the air is such that all but confirmed invalids can spend a portion of their time in enjoying the rich feast she provides. Remember, too, that but for the excessive display of scarlet and yellow in summer you might have had Primulas, Tea Roses, Spiræas, Trumpet Lilies, Lily of the Valley, and Violets indoors while the cold east winds were blowing in spring; and you might have looked through your window and feasted your eyes on thousands of Snowdrops, Crocuses, and waving Daffodils; while at intervals, even during winter, a small opening of the window would have admitted air laden with the perfume of a thousand Violets.

Do not expect John to produce all these in addition to what he does now, he is already overworked. It is the last straw which

breaks the camel's back, and if I am the cause of removing even a few straws this letter will do a little good.—WM. TAYLOR.

#### DENDROBIUM WARDIANUM.

THIS handsome Orchid is so well known that it scarcely needs description, but rarely is such a remarkably fine variety seen as that of which a flower is represented its natural size in fig. 75. The plant from which this was taken I recently noticed in one of the houses under the charge of Mr. Scutt, gardener to A. W. Gadesden, Esq., Ewell Castle, Surrey, the specimen having growths about a yard long, bearing the enormous flowers two or three together, each as large as that shown in the woodcut. The plant was in a basket suspended from the roof of the house over the path, and at once attracted attention, although other richly coloured and imposing flowers were uncommonly numerous in the same structure. The flower selected was 5 inches in diameter

from tip to tip of the petals, each of which was  $1\frac{1}{4}$  to  $1\frac{1}{2}$  inch in breadth. The sepals and petals were of great substance, white tipped with bright crimson; the lip being of a clear yellow hue with two intensely rich crimson blotches at the base. It is doubtful if this superb variety has ever been surpassed in the size of the flower and richness of the colouring.—L.

#### BOUVARDIAS.

BOUVARDIAS may be grown successfully by amateurs if an ordinary amount of attention is paid to them. They are easier to grow than the majority of plants that do not produce half so many choice flowers in return. Their propagation is effected by means of cuttings, which should be inserted as early in the spring as possible. The points of the young shoots about 3 inches in length root readily if inserted in 5-inch pots and placed in the propagating frame or under bellglasses and plunged in brisk

Fig. 75.—DENDROBIUM WARDIANUM.

bottom heat. When rooted the young plants must not be left in the cutting pots until the roots are matted together. As soon as the cuttings are sufficiently rooted they should be at once placed in 2-inch pots well drained. If slight bottom heat can be afforded for a time the young plants will make much better progress, and at the same time increased ventilation will be necessary to maintain a sturdy growth. The shoots require pinching to form bushy plants and lay a good foundation for well-developed specimens. The points of the young plants must be taken out after the first potting, as if allowed to grow unstopped much time is wasted, and at the end of the season the plants would have to be cut back. When they have filled their pots with roots they should be transferred to 5 or 6-inch pots, and repotting afterwards should be attended to as they require it. The compost most suitable is rich fibry loam three parts to one part of leaf soil and cow dung, with plenty of coarse sand to keep the whole porous.

Watering should be done carefully, especially just after the plants are potted, and in all stages of their growth careful applications of water are necessary. After plants have attained the desired size and filled the pots with roots liquid manure may be liberally supplied. As the season advances bottom heat can be dispensed with, and the plants grown under the influence of more air, gradually hardening them ready for the time when the exter-

nal temperature will permit their being placed in cold frames, which will be about the beginning of June. If the plants are properly hardened previous to their removal to cold frames the lights can be removed early in August. It is advisable to keep the plants in pits where they can be protected in case of heavy rains. When the nights become cold the Bouvardias must be placed in a temperature of from  $55^{\circ}$  to  $60^{\circ}$ , where they will continue to bloom for months, and plants that have attained a fair size will not fail to produce their beautiful flowers over a period of six months. After flowering a rest will be required, which can be given by keeping them a little drier and cooler for a time. They can then be pruned, turned out of their pots, partially reduced, and repotted in the compost recommended above. They should have gentle warmth afforded them to start into growth, similar to what would be given to Fuchsias. A vinery just started is a capital place for them. The following are six excellent varieties:—Elegans, Hogarth, Queen of the Roses, Vreclandii, Bridal Wreath, and Maiden's Blush.—WILLIAM BLOMLEY (*Abridged from a Paper read before the Members of the Liverpool Horticultural Association*).

CHRYSANTHEMUMS IN POTS.—The large pots I employed for Chrysanthemums last year had four plants in each; if this was

not mentioned in the article to which Mr. Bardney refers it was a slip on my part. I had none better than these plants in large pots last season, and they certainly require less labour in the supply of watering than plants grown in smaller pots.—R. P. BROTHERSTON.

#### KITCHEN GARDEN.

No time should be lost in planting out Cauliflowers wintered in frames, also those raised and forwarded in heat, as well as early Cabbage, Brussels Sprouts, Lettuces, and Peas whenever the weather is favourable. If a south border is at liberty sow Dwarf Kidney or French Beans 4 inches asunder in rows about 2 feet apart; Osborn's Forcing, Negro, and Canadian Wonder are suitable varieties. Attend to the earthing-up and placing sticks to Peas as they advance in growth, and dust the plants whilst damp with soot, quicklime, or dry wood ashes. In order to obtain a good supply of Peas in August, sow now liberally such kinds as Criterion, Huntingdonian, Telephone, Emperor of the Marrows, and Ne Plus Ultra, which are all tall varieties; among those of medium height are Dr. Maclean, Marvel, Veitch's Perfection, and Maclean's Best of All. The ground for late summer Peas can hardly be too rich and deep, affording them plenty of room. Make another sowing of Longpod and Broad Windsor Beans. Complete the sowing of Carrots and other root crops, preparing the ground for Beet, also Chicory, which may be sown at the end of this or beginning of next month. Lettuces are coming in at last, Stanstead Park taking the lead. Attend to the Cos varieties, and tie up the earliest to succeed the Cabbage varieties. Keep up successional supplies by sowing moderate quantities of seed occasionally; Malta and Suttons' Gem among Cabbage sorts, with Alexandra Cos, are good for summer use. Complete as expeditiously as possible the planting of Potatoes. Plantations of herbs should at once be seen to, inserting cuttings of Sage and Thyme. Divide the roots of Marjoram and Tarragon, and plant in rows about 18 inches apart. Sow seeds of other herbs not increased by division, such as Sweet Marjoram, Basil, Savory, and Chervil, the last being sown about three times a year to keep up a supply in the present month, June, and August. Herbs are benefited by a change of soil, and should have a moderately warm situation; they succeed well on an east border. The seedling Brassicas require care to protect them from small birds and slugs. A little dry soot scattered over the beds will, from its bitter taste, check the birds, but a little quicklime is preferable for slugs. Ply the hoe when the weather is favourable between the rows and about growing plants, and as soon as the seedlings of root crops appear run the hoe between the drills.

#### FRUIT HOUSES.

*Vines.*—The time for planting young Vines has arrived, and where new borders have to be made it should be seen to at once, choosing dry weather for the operation. Drain thoroughly, and have the materials for the border well incorporated. Loam taken from a pasture about 3 or 4 inches thick, chopped up in squares of about 6 inches, adding about a tenth of old mortar rubbish and a bushel of crushed bones to a cartload of loam, with a similar quantity of charcoal, will form a suitable and durable border. Let the depth be 30 inches deep and the width 6 feet to start with. The material should be placed together rather firmly. The Vines for planting are in 8 or 10-inch pots, the canes having been cut back in December and have been kept in a cool house. The buds have started and are a couple of inches long, which is a suitable length. Turn the Vines out of the pots, disentangle the roots, removing every particle of soil, place the Vines in position, spread out the roots evenly, and cover them with about 4 inches depth of soil, working it amongst the roots, afterwards giving a good supply of water at 90°, and mulch with short dung. Syringe two or three times a day according to the weather, and do not attempt to force the Vines into growth, but maintain a temperature of about 55° artificially, and ventilate freely above 65°.

Young Vines planted last spring are now growing, and when the shoots are about half an inch long a little fire heat on cold nights will be beneficial. Rub off all buds but one at each break as soon as the best can be distinguished, and crop lightly; a couple of bunches to prove the kinds will be sufficient. If there are any supernumeraries they may be fruited heavily. There must not be any deficiency of moisture in the border. Thin the bunches and berries in succession houses, bearing in mind that so long as those remain on the Vines they are appropriating the nutriment that would otherwise go to the improvement of the permanent crop. Late houses started in March are making rapid progress; attend to disbudding and tying-out as necessary, closing early, and dispense with fire heat as much as possible. Maintain plenty of atmospheric moisture, and ventilate freely when the weather permits. In the early houses red spider is appearing, and should be combated by painting the pipes with sulphur, but not too thickly. Water the borders where the Grapes are colouring with liquid manure, and mulch the surface of the border with partially decayed manure. A moderate amount of atmospheric moisture should still be maintained, but as the colouring becomes more advanced gradually lessen the supply and allow a free circulation of dry warm air. A full crop of early Grapes is a serious strain on the Vines, and in striving to ripen them in a short time perfection in colour is not always attained, which defect may often be avoided by a moderately low night temperature and a constant supply of dry warm air. Where Grapes are fully ripe a reduction of temperature may take place, keeping up a little moisture in the air.

*Melons.*—The first batch of plants have their fruits swelling freely, necessitating copious supplies of water at the roots, maintaining a moist but at the same time well ventilated atmosphere. Keep the laterals somewhat closely stopped, and thin-out where likely to interfere with the principal foliage. Afford the needful support of the fruit. Later plants are showing fruit, and unless in sufficient quantity for a crop remove the first until five or six pistillate blossoms of a simultaneous growth on each plant are secured. Maintain a higher temperature during the setting period, 80° to 90° from sun heat, and 70° at night, affording water only to prevent flagging, and withhold the syringe and all atmospheric moisture for a few days, ventilating rather freely, and look over the blossoms for fertilising as fast as they appear, it being preferably performed after a few hours' bright sun. Attend to former instructions as to earthing up. In pits and frames maintain a bottom heat of 80° to 85°, and a top heat of 65° to 75° with an advance of 10° to 15° from sun heat. Ventilate a little at 75°, and maintain 80° to 85° during the day, closing for the day at about 3 P.M., but not so early if an advance is likely to be made above 90°. Observe the conditions indicated above when the fruit is setting, and after the fruits are set and swelling let them be placed on pieces of slate, afterwards raising them above the foliage on an inverted flower pot. Continue to make up beds of prepared materials, getting out the plants when the bottom heat is not in excess of 90°. Pot off seedlings, and sow seed for raising plants for successional crops.

*Cucumbers.*—To insure a healthy and fruitful condition of the plants do not omit pruning the plants regularly about twice a week, or the young growths will so crowd each other as to render the operation tedious and injurious, as there is danger of removing that which it is desirable to retain, and of rubbing off the young fruit. Moisture will need to be abundant in the atmosphere and at the roots, or red spider and thrips will soon appear. Fumigation will destroy thrips, but it must be done carefully and repeatedly. Against red spider thinly coat the pipes with sulphur, and fill the evaporation troughs with guano water, and damping the house with the latter at closing. The foliage must not be allowed to flag severely, otherwise shade as little as possible at present. In pits and frames an increase of moisture will be necessary, damping the foliage gently through a fine rose early on fine warm afternoons, closing at the same time, and with the temperature advanced to 85°, admit a little air afterwards for about half an hour. Attend to stopping and thinning the shoots where likely to be too crowded, and maintain a good bottom heat by means of linings of fermenting materials, and afterwards be careful to allow the escape of rank steam, especially

when the sun is powerful. Earth-up the roots a little from time to time, and afford efficient protection over the lights at night. Ridge varieties should now be sown.

*Pines*.—Suckers started at the beginning of March, and plants disrooted at that time and subjected to similar treatment, will be well rooted, and should be transferred to the large pots before they become root-bound. See that the soil is thoroughly moist before potting, and if necessary give a thorough supply. Autumn suckers kept through the winter in pots it is not intended to fruit them in should also be attended to in potting, and if to fruit early in autumn 10-inch pots are large enough for Jamaicas and Queens, and 11 or 12-inch for the most vigorous-growing kinds. A temperature of about 95° at the base of the pots is suitable for newly-potted plants, but after the roots reach the sides of the pots 90° should not be exceeded, as there is danger above that of injuring the roots, especially fruiting plants with roots in an active state at the sides of the pots. Keep the atmosphere about fruiting plants well charged with moisture during the time the house is closed, employing no more fire heat than is necessary to maintain 70° at night, and 5° more in mild weather. Commence ventilating slightly at 80°, more freely at 85°, and liberally at 90°; close with sun heat at 85°, and syringe the plants lightly except those in flower. Water will be required about once a week at this season. Where scattered fruits are ripening and flavour is required, such on the plants should be removed to a house where they can have more air, a vinery where the Grapes are ripe being suitable.

#### FLOWER GARDEN.

Herbaceous plants are among the first to cheer us with their flowers, and are particularly interesting during the spring and early summer months. Complete the dividing and re-arrangement of these plants as may be necessary, and before replanting work-in some fresh soil or decayed manure. *Pyrethrums* have showy flowers, and come in at a time when showy flowers are scarce, and should be grown where cut flowers are in request. There are now some really fine double forms, of which the following are good:—Madame Munier, rosy blush; Marquis of Bute, crimson; Mont Blanc, white; Sturbide, purplish carmine; Captain Nares, crimson; Duchess of Edinburgh, mauve suffused rose; Galopin, deep crimson; J. N. Tweedy, crimson tipped white; Madame Billiard, flesh white; Panorama, white shaded pink; Rev. J. Dix, rosy carmine; Gustave Heitz, rosy pink; and Lady Blanche, white suffused pink. They do well in ordinary garden soil, their Pæony-Aster-like flowers being very effective. *Herbaceous Pæonies* also are fine early summer-flowering plants. Some of the finest are Madame Calot, white tinted rose; albiflora chinensis plena, white; albiflora Whitleyi, white; Marie Lemoine, rosy blush, creamy centre; Docteur Bretonneau, rose, centre pink; atro-sanguinea, crimson; Clarisse, rosy pink, white centre; Etendard du Grand Homme, rosy purple; Edmond Lebon, rose; Prince Imperial, rose, centre white and yellow; and tenuifolia plena, blood red, beautiful. In rich rather moist soil they luxuriate, and once planted take care of themselves, and in flower have an imposing appearance. *German Irises* are fine border plants, doing well in almost any soil and place, and they produce their fine variously coloured flowers at an acceptable time. Some of the finest are Samson, yellow and crimson; Madame Sontag, lavender, yellow centre, lower petal blue feathered white; flavescens, lemon; pallida, lavender; Rolandiana, reddish purple, blotched white; atro-purpurea, bluish purple; Donna Maria, white, suffused with lavender; Bridesmaid, white, veined purple; Raphael, nankeen and purple; Lucrece, sulphur, lower petals lavender; and versicolor, violet and white. Then there are the *summer-flowering Chrysanthemums* that begin sometimes flowering in June and continue for months, being both useful and decorative: and of those Album plenum, white; Golden Button, yellow; Delphine Caboché, purplish rose; Frederic Pelé, red; Adrastus, rose; Cassy, light rose; and Andromeda, yellow, are good varieties. *Delphiniums* also are fine for cutting and have great decorative value, especially the double forms, as Pompon Brilliant, Keteleeri, grandiflorum plenum, Amede Hans, Beatsoni, and Madame Richalet; and of singles nudicaule, Belladonna, alopecuroides, Madame Lelandais, Wheeleri, and Cashmerianum.

*Phloxes* afford very handsome flowers and make an effective dis-

play. Both the early-flowering section, as *P. suffruticosa*, and late-flowering, as *P. decussata*, should be grown. Of the early-flowering the following are fine—The Queen, white; Clipper, white shaded lilac; Miss Robertson, white; Morello, rosy crimson; Lady Napier, white and fragrant; William Blair, rosy purple, crimson eye; Union, deep rose; E. L. Lewan, mauve; A. M. Kinnon, rosy purple, crimson eye; Duchess of Athol, white, rosy crimson eye; Forward, white, striped and clouded rose; and Purple Emperor. Of the late-flowering section Miss Macrae, white, purplish crimson eye; Madame la Comtesse de Turenne, white, lilac centre; Madame Marie Saison, white, shaded red; Mons. Malet, lilac, white centre; Mrs. Austin, white, crimson eye; Ball of Fire, red; Mons. de la Devanschuff, rose, purple centre; Mrs. Balfour, crimson; Lothair, scarlet, shaded purplish violet; Madame Henderson, rose; Souvenir de Berryer, rosy salmon; and Jessie Laird, white, violet crimson eye. *Potentillas* are not so often seen as they deserve to be. Some of the best are Velours Pourpre, purple; Louis Van Houtte, crimson; Alfred Salter, scarlet and orange; Eldorado, purple, edged yellow; purpurea plena, crimson purple; Toussand, L'Ouverture, bright purple; La Vesuve, red, edged yellow; Cameleon, purple, striped yellow; Chromatella, yellow; California, golden yellow; Panorama, yellow and light purple; Hamlet, crimson; and Mars, maroon. Pentstemons have been much improved of late years; and though requiring the protection of a frame in winter make a fine display in the borders, and are useful in affording a supply of flowers.

#### PLANT HOUSES.

*Orchids*.—A number of the East Indian species are now growing, and a temperature of 70° at night, falling 5° on cold nights, will be necessary, and 80° by day. Ventilate from 75° more or less on fine days from about 9 A.M. to 3.30 P.M. Shading is also necessary, and of such description as to exclude the fierce rays of the sun. Roller blinds are the best, as permanent shading produces a weakly growth in the plants. Early in the morning and again on fine afternoons syringe the plants, but avoid wetting the flowers, especially of Phalaenopsids. Syringe plants on blocks two or three times a day, and keep the surface of the pots damped. Dendrobiums require more water at the roots, but it must be carefully afforded or the roots will perish, especially in the case of overpotted plants. Such kinds as *D. Cambridgeanum*, *D. Devonianum*, *D. Parishii*, *D. Wardianum*, and many others succeed best in baskets suspended from the roof; but free growers, such as *D. densiflorum* and *D. Farmeri*, are best in pots. Cattleyas in growth must have plenty of moisture, separating them from those at rest. *C. gigas* and *C. Dowiana* should have a day temperature of 60° to 70°, never less than 55°. Continue to top-dress and repot any plants making fresh growth. Let *C. labiata* and *Lælia elegans* have the warmest part of the Cattleya house, affording good drainage and the best fibrous peat. Repot Anguloas and Lycastes, employing a mixture of equal parts peat, sphagnum, and charcoal the size of hazel nuts. They require plenty of water at the roots and must have good drainage. Burlingtonias may be grown in deep baskets, with large lumps of charcoal and sphagnum, and suspended in the East India house, affording plenty of moisture. Keep Barkerias cool and damp, as a dry atmosphere is injurious; syringe two or three times a day. Cypripediums must have plenty of water, or the plants and flowers will suffer, particularly *C. caudatum*. *Coelogyne cristata* starting into growth should be syringed frequently, and when fresh roots are formed supply water liberally. Shade Miltonias, and sponge the leaves to remove scale. Fumigate frequently to destroy thrips.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

##### GREENHOUSES.

GREENHOUSES and conservatories are now very gay, but the easterly winds accompanied with scorching sunshine has shortened the duration of many flowers considerably, and has encouraged the rapid spread of insect pests, notably green fly. Fumigation with tobacco is perhaps the most generally effective remedy, but this proves injurious to the expanded blooms of Azaleas, Deutzias, Cytisuses, and Pelargoniums, and these should be either transferred to a pit or other house, or be placed on the floor of the house and screened with mats. The house should be fumigated in the evening, taking

care that the plants have their foliage dry, repeating the operation the following morning or evening; afterwards the plants should be well syringed. Some of the advertised insecticides are easily applied, effective, and do not injure the foliage when the vendors' instructions are carefully followed. After dipping plants they should be placed on their sides and freely syringed with clear water.

*Cinerarias*.—Those now expanding their blooms should be assisted with occasional supplies of weak liquid manure. If seed is to be saved at once remove inferior varieties or the strain will deteriorate. As a rule it is best to buy seed of good advertised strains. If a few early plants are wanted sow a pinch of seed at once; employ a well-drained pan with fine sandy soil, render the surface level and tolerably firm, watering this an hour previous to sowing, pressing in the seed, and very lightly covering with sand. The pan should be covered with glass, placed on a greenhouse shelf, and carefully shaded. If the surface is found to be dry at any time water through a very fine-rose pot, or partially submerge them in a bucket of water.

*Chinese Primulas*.—Part of the seed of these may now be sown. The remarks upon sowing *Cinerarias* are applicable to these, with this important difference—the pans must be plunged or stood in heat, nothing being more suitable than a Cucumber frame. If pots are substituted for pans at any time they should always be at least half filled with drainage. *Primulas* being saved for seed should be placed on a sunny shelf and watered when required.

*Fuchsias*.—Cuttings of these strike readily enough in a frame over a gentle hotbed. Do not crowd the cuttings, and when struck pinch them back, potting off when breaking afresh. Old plants that have been cut back and are now starting into growth should have the greater part of the old soil shaken from the roots, shortening these and returning the plants to as small pots as can consistently be used, taking care to shake down the soil well among the roots; any light loamy sandy soil will suit them. The plants will start more freely if a little heat can be given.

*Balsams*.—Sow seeds of these thinly in pots or pans, and place them on a greenhouse shelf. Keep the soil moist but avoid saturating it. The seed would germinate much more rapidly in heat, but sturdiness should be aimed at, which is best attained by raising the plants in a cool house.

*Chrysanthemums*.—If bushy plants of these are required pinch the shoots back to the fourth joint, potting off recently struck cuttings, giving a shift to those already singly in pots when they are pushing afresh. Untrained standards give the finest blooms, and this plan admits of a greater number of plants being grown on a given space. For these select and pot on the sturdiest plants, and do not pinch back. A cold frame is most suitable for *Chrysanthemums* at this time of year, and they may yet be propagated.

## THE BEE-KEEPER.

### INTRODUCING AN ALIEN QUEEN—PREVENTION OF SWARMING.

I. I INTEND to procure a Ligurian queen, but seeing there is so much risk in enthroning her, how would it do to make a swarm for her, and so give them all strange quarters? I could easily do this, as I have a straw skep I intend to keep for breeding from which is very strong of bees. I could drive a fair swarm from it and give it the foreign queen; or shall I take the old queen from the straw skep and give it the new one, thereby giving me a chance of a swarm of hybrids this season?

II. I have a very strong "Woodbury" that I intend to devote wholly to honey-gathering; it is at present full of frames, the oldest of which are two years in the hive. I have crates of sectional supers ready to put on; but I am at a loss to know exactly what day to put them on, as I know there is danger of putting them on too soon. They are very strong in bees, and young bees were out some time ago. I have also been stimulating them with the "bottle" of thin syrup. Please give me a few hints how I am to keep it wholly honey-gathering without swarming.—COMBER.

[You ask whether you can drive a swarm from a populous skep and give the purchased queen to it upon the old stand, or whether you can drive a swarm from the skep and give the new queen to the

remaining bees upon their combs? The answer is, Yes, to both queries; but the implied suggestion that in these ways you prevent all risk in the introduction is certainly not accurate. The methods of introducing queens may be varied *ad infinitum*, and failure and success are possible with all. With the hope that the latter may be yours we give a few hints which may be of general interest. If you act upon your first-mentioned plan, "giving the queen to a swarm upon the old stand," it will not be necessary to drive a swarm at all—a fortunate circumstance, as driving would involve the necessity of seeing the queen so as to be perfectly certain that she was left in the skep. Although an expert may make artificial swarms at almost any time from March to October, it is desirable here to repeat the oft given warning, that those with limited experience should not attempt it in indifferent weather or with stocks that are not extremely strong in bees. Satisfied upon these points you may proceed thus: Into the new hive put frames of comb, filling it with them if enough can be spared, and then upon the morning of a day when the bees are flying freely the foreign mother is confined in a dome cage of wire cloth upon one of the combs, the skep being immediately removed to a new station, and the frame hive made to occupy its place. The bees returning from the fields with their loads will after some hesitation enter, but finding all changed within will quickly re-appear at the door to make another examination on the wing. By degrees they will seem to determine that their new home is better than none, and making the best of it will gather around the queen, deposit their stores, and return to the fields for more. In two days the cage may be removed with almost positive certainty that the queen will be well received. A few cautions here are important, as success depends upon many little details, some of which may easily be overlooked. 1st, The cage should stand over cells containing some honey or the queen may suffer, but the cage on no account should have its edge driven into sealed cells, as the bleeding honey would smear the queen and possibly cause her death. 2nd, Honey should be coming in abundantly so as to make robbing unlikely, as the bees under the circumstances would probably not defend their new home. (The presence of brood in the combs given would save from danger from robbing, but it would increase the difficulty in securing a friendly reception for the queen, as royal cells might be started. The best safeguard is a good honey yield.) 3rd, The removed skep should for some days before the operation have been disguised, so as to give it the same appearance the frame hive will have when taking its place. A sack or horsecloth if thrown over it will assist, this being of course transferred to the frame hive when that is put upon the old station. 4th, If skeps stand very near the one operated upon many bees are likely to seek shelter in them, so weakening the swarm and perhaps causing queen-encasement in the skeps. 5th, If combs in frames are scarce two combs will suffice if the other frames are supplied with foundation. As soon as the queen is accepted a sheet of foundation may be placed between the two combs, and as the swarm can bear it others should follow, the original combs passing to the sides of the hive. This plan with judicious feeding will soon produce a hive of perfect combs with a dense population. 6th, As the swarm cannot hatch any new bees until its twenty-third day, and as many of its members were old at the first, it will considerably reduce in numbers before that time. To prevent this a frame or so of brood and eggs from the Woodbury that you desire not to colonise may be given. Foundation will of course take the place of the renewed combs.

Your second plan has two disadvantages and one advantage. Your Italian queens would be in a hive with fixed combs, giving you less chance of raising other queens from her, and you would be in danger by driving a swarm and putting it upon the old stand of unduly weakening the skep. You must secure the queen of course, but a few of the driven bees only need be put with her into the frame hive. You must be very cautious also that no queen cell is in progress in your skep, or your queen stands little chance. The advantage lies in this—that the old bees would go to the driven swarm, and the youngsters remaining could be easily induced to accept a mother-in-law.

The absolute prevention of swarming can be secured by no system of management, but this end is generally achieved by getting a hive filled with brood in all stages by constant enlargement of the brood nest, so that after supering the ceaseless hatching of bees supplies labourers for the supers and space in which the queen may continue laying. Let the super be put on just before the bees begin to fail to find room for all their brood and stores, warmly covering the former so that it may quickly rise in temperature, instead of being, as is too often the case, a means of allowing the heat of the brood nest from leaking away.—F. CHESHIRE.]

### APIS DORSATA.

(A Translation from the *Bienenzeitung*, and communicated by Alfred Neighbour.)

MUCH has been said and written about this bee, the largest with which we are acquainted. The accounts which have been published on *Apis dorsata* are nearly all by travellers who have chanced to see it, and who in their reports mostly refer to it incidentally only. Considering that these travellers were not bee-keepers, and therefore had but little or no knowledge of bees, the imperfect and incorrect information they give us as to *Apis dorsata* is easily to be accounted for; but this state of affairs is no

longer to continue. Bee-keepers who take an interest in this bee have now a fair prospect of obtaining reliable information concerning it, and may perhaps be able to see a few specimens, or even obtain a colony of these bees at some future time should it be considered worth while to introduce them into Germany.

Not long ago Professor Dr. Zadach of Königsberg, in Prussia, made it known to the Natural History Society of Brunswick that a young savant, Dr. Grabowsky, was going to pay a visit to Borneo for the purpose of collecting insects, plants, &c. It occurred to me that this would be a favourable opportunity of getting some information about *Apis dorsata*, which has its home in Borneo; I therefore wrote at once to Professor Zadach, requesting him to induce Dr. Grabowsky to look for *Apis dorsata* in Borneo, to observe it carefully, and furnish me with particulars in due course. In writing to Dr. Zadach I did not omit to state precisely the points on which I wished to be informed more particularly. I received a reply by return of post, in which he informed me that it would give him very great pleasure to comply with my wishes. We must now see what comes of it.

We may perhaps be able at a still earlier date to obtain some exact information on *Apis dorsata*. I received the other day a letter from Mr. Frank Benton of Larnaca, in the Island of Cyprus, in which he informed me of his intention to hunt up *Apis dorsata*. The following is a translation of part of his letter:—

“Larnaca, Island of Cyprus,  
“Dec. 7th, 1880.

“Since I last wrote to you my health has improved considerably, and I am well enough now to undertake another voyage in the interests of bee-keepers. My plan is the following:—Leaving here by the Austrian Lloyd steamer on the 21st inst., I shall first pay a visit to Beyrout and Jaffa, and remain there for a short time. From Jaffa I shall go to Port Said and then to Suez, Aden, Bombay, Colombo (Ceylon), Singapore, and Batavia (Island of Java) perhaps also to Timor, Flores, and the Island of Celebes, and if possible and convenient to me also to the Philippine Islands and Borneo. I intend to take with me twenty-five to thirty colonies of Cyprian bees as well as some Syrian bees, and to bring back with me fifty to one hundred queen bees accompanied by some worker bees. The queens which I intend to take home with me to the Island of Cyprus are to be of the very best races obtainable, such as *Apis dorsata*, *Apis zonata*—i.e., if I become convinced of the good qualities and value of these bees. I shall further endeavour as far as possible to collect seed of the various melliferous plants which may appear valuable to me, and which are not to be found in my native country. My plan is not an unpremeditated one, but has been discussed for a long time, and the time has now arrived to carry it out. The bees which I shall be able to obtain will be under my own personal care, and I hope to reach home safely with a good many queens. My boxes for transporting them are large, and so arranged that I can let the bees have little or plenty of air according to their requirements. The food consists of sealed honey in old combs, and sugar cake and water. In most cases I intend to feed the bees in both at the same time, and to give them sealed honey as well as sugar and water in one and the same box. I shall not stay longer in the East Indies than will be necessary for my purpose, and I hope to be back in April or even before. The honey harvest in Cyprus has been worse than any I can remember in the whole of my experience. The bee-keepers of this Island express themselves similarly. Since May the bees have literally collected nothing. The natives lost nearly four-fifths of their bees by starvation, moths, and hornets. The latter have done a great deal of damage during the long and hot summer which we had here.”

Thus writes my friend Mr. Benton. I shall not fail to report the result of his endeavours concerning the *Apis dorsata* on a future occasion.—C. J. H. GRAVENHORST.

*Footnote in the “Bienenzeitung.”*—The Editors have been informed by Mr. Frank Benton of his intended visit to India, and they purpose to write to Mr. Benton to Batavia (Island of Java) respecting *Apis dorsata*. Mr. Vogel received some very special information about this species of bees direct from India a few years ago, and in his opinion the introduction of the species (not race) would be of great scientific interest, as its hybrid offspring especially would afford bee-keepers some very valuable information. To acclimatise this bee in Germany will be impossible, as coming from the tropics it will not be able to live through our northern winter. This was our experience with *Apis fasciata*, which dies in the hive when the temperature of the air outside shows from 3° to 5° R. frost, though the walls of the hive may be both thick and warm. Nevertheless, in the interest of science we recommend the importation of *Apis dorsata*, and Mr. Vogel will announce in due course how to make it safely and without difficulty live through the winter.

There can be no question of any practical importance attending the introduction of *Apis dorsata* into Germany, but it might be possible to acclimatise it in the southern States of the United States of North America.

#### TRADE CATALOGUES RECEIVED.

Ewing & Co, Eaton, near Norwich.—*List of New Roses for 1881.*  
Thomas Painter, Smallwood, near Scholar Green, Stoke-on-Trent.—*Catalogue of Dahlias.*  
Frères Simon Louis, Metz.—*List of Miscellaneous Plants.*

\* \* All correspondence should be directed either to “The Editor” or to “The Publisher.” Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Wiring a Cucumber House** (W. W.).—A foot from the glass is a good and safe distance for the wires, but if the house is very low 2 or 3 inches less will do very well. Nine inches apart is suitable for stretching the wires.

**Evergreen Wall Plant** (T. W. G.).—The low wall is, we presume, on the outside of the conservatory; and as you require “a small-foliaged evergreen that grows closely and not too quickly,” we think *Cotoneaster microphylla* will be as suitable as any.

**Hellebore Tea** (Idem).—Two ounces of powder is sufficient for a gallon of water. A correspondent who has used it effectively finds it the best to first mix the powder with hot water to the consistency of cream, adding the cold water afterwards.

**Asparagus Small** (L. I. K.).—Without having fuller particulars than can be conveyed on a postcard we cannot satisfactorily answer your question; besides, we are quite unable to decipher the words relative to the dressing you have applied. The nature of the soil may be unsuitable, or the heads may have been cut too long and closely. Unless you have good growth in the summer you cannot expect to have fine heads in the spring. You will perhaps, however, have finer heads as the season advances. Are the beds very full of plants? Overcrowding results in small produce.

**Strawberries not Swelling** (Old Subscriber).—The plant you have sent is well grown and healthy, and the roots have not received any injury by liquid manure. We attribute the condition of the fruit to defective fertilisation. In all probability the flowers opened when the weather was dull and ungenial, and the pollen was not liberated. Had you drawn your hand gently along the trusses at midday the fruit in all probability would have set and swelled much more freely. Every berry on the plant you have sent is more or less malformed, which is conclusive evidence of imperfect fertilisation.

**The “Musk Tree”** (K.).—The plant which you state is known under the above name is *Aster argophyllus*, a member of the natural order Compositæ. It is a native of Van Diemens Land, whence it was obtained by Messrs. Lee and Kennedy at the beginning of the present century, and in a wild state it acquires the dimensions of a small tree. It is well worth cultivating in a greenhouse, as the leaves are very ornamental owing to the silvery whiteness of the under surface, and their musky perfume is also very pleasant. Ordinary loamy compost suits it very well. Specimens are occasionally seen in a collection of old plants, but it is comparatively rare.

**Heating Greenhouse** (J. E. Osborne).—Your house would be best heated by a stove boiler, which could be readily placed in a small shed as you propose at the back of the greenhouse, and would be, like your house, a tenant fixture. All that will be necessary would be to isolate the smoke flue from the woodwork by sheet iron or some other non-combustible material, and exercise the usual precautions in stoking against accident from fire. Have the boiler as near to the greenhouse as possible, and employ 4-inch preferably to 3-inch pipes, the former affording a more regular temperature. Thirty-six feet of 4-inch piping, or a flow and return along the front of the house and one end if a lean-to, or if a span along the sides of the house and one end, will give you all the heat necessary in the severest weather.

**Rooted Cuttings** (Killie).—If you ordered rooted cuttings you had a right to receive them, and if cuttings were sent just as taken from the plants a less price ought to have been charged for them. The cuttings you sent were admirably packed, and arrived in a perfectly fresh state. Some of them are small, yet they are sturdy, and much better than if they were taller by being drawn up in heat. We have not the slightest doubt that we could strike every one of them, and produce fine flowering plants. It would be a mistake if the vendor made the cuttings ready for insertion. In the first place, the cut ends might be injured during transit; and in the next, he might be blamed if they failed to grow. Such cuttings as those you have sent should be inserted immediately they are cut close under a joint, and they would not have been better if they had been prepared by the vendor.

**Hibiscus sinensis Culture** (Idem).—This plant can readily be propagated when the wood is young or half ripened if the young shoots are selected and inserted in sandy soil round the sides of a 5-inch pot. The pot containing the cuttings should be placed in heat and shaded from the sun. If a bellglass can be placed over the cuttings they will strike the more quickly. When rooted, pot the young in 3-inch pots and again place them in heat, and as soon as they commence growing the points of the young shoots should be taken out to cause them to branch. Potting should be done from time to time as the plants require it, affording good drainage, and pressing the soil moderately firm. The size of pots in which they are to bloom entirely depends upon circumstances. If a good specimen is wanted, stopping must be done as occasion requires, and

the strongest growths tied out to form the base of the plant. The bush shape is the most suitable for the Hibiscus. They will, if strong, flower in 6, 7, and 8-inch pots fairly well, but when wanted to flower the shoots must be allowed to extend instead of being stopped. A plant that has formed four or five shoots can be allowed to extend and bloom. They must be grown under the influence of light to solidify the wood as it is made, or the supply of flowers will be insignificant. After blooming, the plants should be carefully watered and kept through the winter in a temperature of about 50° to 55°, and be then somewhat drier at the roots to induce rest. About the month of February they should be well cut back, and then allowed to break into growth, afterwards repotting by reducing the old ball a little, and if larger plants are not required they can be replaced in the same sized pots. While growing a good supply of water will be needed, and when the pots are full of roots weak stimulants can be given. They will grow luxuriantly in a mixture of peat and loam, or loam and a seventh of decayed manure, with plenty of sand to keep the whole porous.

**Gymnostachium Culture (Idem).**—These are of easy cultivation, and can be successfully grown by anyone having the convenience of maintaining a stove temperature. They are easily propagated by cuttings, which root quickly if inserted in sand and placed in brisk heat in a close frame or under a bell-glass and well shaded. After the plants are well rooted specimen pans can be made up with a number of them. The centre of the pan should be elevated considerably, but this should be carried out according to taste. They can be grown to look well in baskets or in small pots. They delight in a light soil, which should consist of fibry peat, the small particles of soil being shaken out, sphagnum moss, charcoal, and plenty of sand. While growing abundance of water should be given and the plants liberally syringed. They grow with the greatest rapidity in a close moist atmosphere well shaded from strong light. When specimens are made up and the plants have grown a little the growth should be pegged down, when the stems will quickly throw out a number of roots. These plants are very beautiful when grown in connection with small-growing Ferns to cover vacant walls in stoves. They also look very attractive when growing amongst the moss on Orchid pots, but must be kept in due bounds. *Gymnostachiums* will not fail to grow luxuriantly if plenty of heat, water, shade, and a light compost is given them.

**Salvias for Winter (Idem).**—The following are all worthy of cultivation—*S. splendens* and its variety *Brautii*, *S. Pitcheri*, *S. Bethelli*, *S. Heerii*, and for spring *S. gesneriflora*. Dark green paint would look the best for your hurdles.

**Vine Management (A Yorkshire Curate).**—We submitted your letter to the writer of the article to which you refer, and he replies as follows:—"According to the description of the wood and leaves your Vines made last year the treatment applied to restore them to health and vigour was right, and you cannot do better than persevere with the same means. Shoots 6 inches long in three weeks is very satisfactory, but five old rods and seven young canes in a house only 12 feet long are too many by half. It is too late to cut any of them out this season; but if the young canes show sufficient bunches to form a fair crop we advise you to take every shoot from the old rods and give the house entirely up to the growth of the young ones, as it is from them you will derive the most benefit in future. Denuded of their leaves and side shoots the old rods will not interfere with the growth of the young canes, and the former can be cut away altogether next pruning time. 'Just moist' is not sufficiently wet for the inside border now that the roots will have so much demand on them. A thorough watering once a fortnight will be needed so long as the Vines are growing, and unless the rainfall is abundant the outside border should be treated in the same way. Liquid manure is preferable to clean water. That from a cowshed is good, and so is guano, dissolving 1 oz. to every 4 gallons of water. One bunch to every foot run of rod is what we generally allow as a good crop; and if you can secure this, although the bunches may be small, we would not let more remain under the circumstances. The leafless rod is included in the above rate; but the bare rod shows the further necessity of encouraging the young canes. The straw should be removed from the surface of the border, and a 4-inch-deep coating of good manure be substituted for it. The haybands will do no harm through being allowed to remain. One half of the berries may safely be thinned out before they are the size of peas, and if they become too close as they swell a few more may be taken out before they commence colouring."

**Man-eating Tree (T. J. S.).**—We have made inquiries, and cannot learn that any tree known under the above name exists in England. Some time ago an article was sent to us on the subject, but it was of such a sensational character that we refused to publish it. You have probably seen the same article in print somewhere; and if so, our opinion of it is that it was founded on some fable that originated in uncivilised minds, and was turned to account by manufacturers of paragraphs of "startling information."

**Grape Bunches Withering (R. Davies).**—The most probable cause of the bunches withering is a sudden check, such as would be likely to arise from the prevalence of such prolonged cold as we have experienced lately. The days have been very bright and the air unusually cold, which in itself would do no harm unless it were admitted in such quantity as to cause excessive evaporation from the leaves and so check the supply of sap to the bunches, and they would in that case curl up and shrivel. It certainly is a check of some kind, and this we think the most likely one. Indeed, we have in the centre of a house two Muscat of Alexandria, upon which, at the top of the house, the bunches have shrivelled in a similar manner, entirely due to the sliding light being let down over them admitting a current of cold air. At the lower portion of the Vines the bunches are all that could be desired, and the foliage is good. It is better when the external air is cold to allow the temperature of the house to rise 5° to 10° than to admit a quantity of air to reduce the heat, which usually results in a disastrous check. The bunches may also have withered from the roots in an outside border not being active so as to meet the demands of the foliage. More moisture in the atmosphere would have done much to remedy the evil, especially if accompanied with a few degrees higher temperature at night. There is yet another, and by far the most frequent, cause of the bunches shrivelling—viz., immature wood. This may result from the roots being in a badly drained, consequently wet and cold border, or from not attending to the conditions essential to the maturation of the wood by insuring a free circulation of air and a warm rather dry atmosphere. It may also arise from overcropping, but this can hardly apply to your case.

**Vines and Bees (M. C., Worcester).**—By all means retain your bees, and increase them too if you desire to do so; and if the Vines do not succeed it will certainly not be the fault of the industrious insects. We have had ten hives within as many yards of a vineyard that contained many more varieties of Grapes than you have, and all of them produced satisfactory crops.

**Broccoli for Succession (J. E.).**—This further reply to your letter has been sent to us by a gardener of great experience. "Walcheren is not properly classed as a Broccoli, but is (as should all that head the same season be classed)

a Cauliflower. The term Broccoli as now applied is a misnomer. It originally referred to an open or somewhat branching head, but is now applied alike to those plants which have close heads—i.e., Cauliflowers, whether they head the same season as sown, or not until the following season. In order to obtain a succession of Cauliflowers (cooks call Broccoli by that term) all the year round, a sowing should be made the third week in August, and the seedlings should be pricked under handlights or in frames early in October. They will afford heads in June from the handlights. It is well to sow some early kind, as Early London or Erfurt Mammoth, which precede Walcheren by ten days or a fortnight. Another sowing made on a warm border from the middle to the end of March of Walcheren, will come in late in July or early August; another sowing of the same about the middle of April will come in in late August or early September, and Veitch's Autumn Giant sown at the same time will succeed them. A sowing of Walcheren the middle of May will yield heads in October onwards, and by lifting the plants when the heads are the size of a teacup, and laying them in in pits or frames with protection in severe weather, a long succession may be secured. Veitch's Self-protecting Autumn and Snow's Winter White Broccolis sown early in April will give heads by December; and in an ordinary winter, by lifting and protecting as described for Cauliflower, heads may be had up to February or March, when Penzance sown early in April will come in, followed by Cooling's Matchless and Leamington in late March or early April, and succeeded by Lauder's Goshen, Wilcove, and Model, a very fine late kind. These may be over in an early season by early May. In a late one heads may be cut in June; but to secure an unbroken succession some of the latest should be lifted when the heads are not larger than a teacup and laid in under a north wall. Indeed to secure a late supply of Broccolis, plants at planting time should be planted on a north border so as to succeed those in the open quarters. In such borders we have had Wilcove equal to any summer Cauliflower in May, and Goshen and Model as late as the middle of June, and shall have them this season. All late Broccolis should be sown in April. Sown in June some of them will not head at all. In warm localities Snow's Winter may be sown in May, it being half Cauliflower."

**Names of Plants (W. B.).**—Mr. Wm. Paul thinks your Rose is *Monplaisir*, which he describes as an excellent variety for growing under glass if "starved and not pruned much," but the flowers rarely open well out of doors. (*E. S. Clarke*).—Your Camellia is probably a sport from *Eclipse*, which occasionally produces flowers exactly like the one you have sent. It used to be grown in the Waltham Cross Nurseries, and probably is still included in Mr. Paul's collection. (*W. H. Myers*).—1, *Epimedium pinnatum*; 2, Specimen very much withered, but resembled *Gesnera Blassi*. We have received other plants presumably for naming, but no notes accompanied them, nor have been received by post in reference to them.

#### COVENT GARDEN MARKET.—APRIL 20.

No alteration to quote. Prices remain the same; business quiet.

#### POULTRY AND PIGEON CHRONICLE.

#### THE FIELD CULTURE OF GOURDS AND PUMPKINS FOR CATTLE FEEDING.

MANY of the Gourd family are used for culinary purposes in most countries, especially in France and other continental States, as well as in America and Canada, but except the dwarf Marrows they have not hitherto been generally appreciated in this country for culinary purposes. Our object in the following remarks is to show how these fruits can be rendered useful as food for cattle, especially in the eastern and southern districts of England. In

order to illustrate this in a practical manner we will give some experience of a grower of this fruit in Hampshire at Bursledon, near Southampton—Mr. Joseph Blundell, who in 1860 commenced growing Gourds for his own amusement; and after having obtained as great a variety of seeds as he could from every country where they are cultivated, and having grown them on his own farm for several years, he conceived the idea that some kinds might be made available for feeding of cattle, and for extending their culture by the sale of seed of the kinds best adapted for the purpose, being offered to the public under the title of “cattle Melons” and “cattle Marrows.” In 1864 a considerable quantity of seed was sold; in 1865 the sale of seed became still more extensive, and was sent to growers and seedsmen in every part of the kingdom, also to America, Australia, and New Zealand.

We will now give a copy of a circular that was published by the gentleman referred to, calling the attention of growers to the seed for sale, headed “The Cattle Melon and Cattle Marrow of 1865.” “Having during the past season supplied a large number of growers with seeds of my cattle Melon and cattle Marrow I need scarcely add that they have been extensively grown in nearly every county of England, also in different parts of Ireland and Scotland. Many growers have written me very satisfactory accounts, both of the large size of the fruit produced, as well as the abundant quantity per acre. The correspondents have agreed in a remarkable manner as to the feeding value of the fruit, some having given them with good effect to horses, some to cows and pigs, others to sheep, all accounts concurring as to the avidity with which the animals consumed them, to which I beg to add my own experience of the past season. My crops both of Melons and Marrows—some of which have been produced as an intermediate crop with Mangolds, others grown by themselves—have proved very abundant, and much superior to the produce of the two previous seasons, in both of which I grew 40 tons per acre. I have proved the value this season of other sorts and varieties than those previously grown, and the result is very satisfactory both as to the cropping and feeding value of the new sorts; in fact, some of the Marrows, which weighed 85 lbs. each, grown in the open field are an immense improvement upon any I had before seen. The combined growth of both Melons and Marrows on the same land, too, is particularly advantageous, some coming early to maturity with great numbers of fruit and but little foliage, others throwing out luxuriant runners, producing fruit of immense size and valuable feeding properties. As an instance of this I give the letter I received from Dr. Voelcker, and his analysis of part of a fruit, which weighed 54 lbs.

“11, Salisbury Square, Fleet Street, London.  
“November 22nd, 1865.

“DEAR SIR,—I have the pleasure of enclosing a copy of an analysis of your cattle Melon. You will find oil mentioned as a constituent of this specimen of cattle Melon, and in comparing the results with the composition of your former cattle Melon you will observe a larger amount of albuminous compounds (flesh-forming matters) in the last variety than in that previously analysed by me. These differences are due to the fact that in the present instance the seeds in due proportion were mixed with the flesh, and both analysed together. The seeds are very oily and rich in flesh-forming matters, and have the oil and larger proportion of flesh-forming matters in the present analysis.—Yours faithfully, AUGUSTUS VOELCKER.

“Composition of cattle Melon sent by Mr. Jos. Blundell, Bursledon, near Southampton :—1, General composition :—Water, 92.98; organic matter, 6.42; mineral matter (ash), 0.60; total, 100.00. 2, Detailed composition :—Water, 92.98; oil, 0.78; albuminous compounds (flesh-forming matters containing nitrogen, 0.245), 1.53; sugar, gum, and digestible fibre, 2.51; woody fibre (cellulose), 1.65; mineral matter (ash), 0.60; total, 100.00.”

“The foregoing analysis is certainly favourable, inasmuch that it not only exhibits valuable properties for the feeding of milch cows, store pigs, &c., but also constituents really essential for

fattening animals—viz., oil and albuminous compounds, including flesh-forming matters, in addition to sugar, gum, &c. I was, in fact, quite prepared to expect a good analysis from my new sorts grown this year, my stock having done so well upon them. The young store cattle, both Devons and Shorthorns, are receiving only a limited quantity of Melons and Marrows with wheat straw, and nothing can show finer condition than they do. The pigs and dairy cows have also a liberal allowance of these fruit daily; the latter get them carted on the pastures, where they are spread and chopped with a spade. In this way they are all consumed without waste. The fattening bullocks have received no other root or fruit, except the Melons and Marrows, for the past seventeen weeks, which are cut with the Gardner's cutter, a small quantity of Barley and Bean meal being mixed with the cut fruit, and straw given *ad libitum*. Upon this feeding they have all fattened well, and will be sold for the Christmas shambles.”

After giving this quotation relating to their use as cattle food, and as an illustration of what has been done by this experimental grower, we will now proceed to state what we have seen and the practice of others as to the culture and value of Gourds. This food for cattle was never intended to take the place of Mangolds or other root crops, but merely to fill up a vacuum in the months of August, September, October, and November before the root crops were ripe. It has also proved of advantage where grass is short in the autumn months; and properly cultivated Gourds prove an excellent food for the use of dairymen, cow-keepers, and the owners of a cow or two in suburban villa farming, because we have no root or fruit which is better adapted for feeding cows where first-class butter is required, this fruit being entirely free from all acrid matter, or anything likely to injure the flavour of butter, such as Turnips and Cabbages. All soils suitable for the growth of root crops where the climate is mild and moist will produce cattle Melons, and the cultivation and preparation of the land may be the same as for roots. The manure most suitable is found to be yard or town dung, otherwise guano or night soil nitrate of soda, or any manure rich in ammonia. They are best grown as a mixed crop, in order that room may be obtained for their trailing habit of growth, and for the prevention of the wind rolling the runners over, which greatly impedes the future growth. For this purpose two rows of Mangolds, Potatoes, or Cabbages may be grown 2 feet apart, then dibble the Melon seed on one ridge the same width as for the two rows of Mangolds, &c., applying the same quantity of manure as for rows of roots, thus growing alternately two lines of roots and one of Melons. The manure should be buried in the centre of the stretches and ridges, and the Melon seed hand-dibbled  $1\frac{1}{2}$  inch deep, about 2 feet apart directly over the manure, about the first week in May. They are easily produced and cultivated at as little expense as ordinary root crops, and prove an excellent alternation where the constant repetition of root crops has rendered their growth difficult and precarious. We have often seen fine fruit grown upon heaps of compost manure intended for pasture land, also on borders near hedges or fences. A hole dug 2 feet square with a shovelful of manure buried will often give an abundant crop, the land and adjoining hedges being loaded with large fruit. They are often cultivated in America amongst Maize plants, and we have seen them so in the south of England. We have also seen Sunflowers grown amongst them, and these furnish a large quantity of poultry food, and answer a good purpose in preventing the runners of the Gourds rolling over before the wind. Of course the Gourds are sometimes grown alone, and we have seen enormous crops, especially where subject to irrigation. A grower in Somersetshire grew the dark green American variety very large, two fruits upon one plant, one being 160 lbs., and the other 120 lbs. The yellow Gourd in France has been known to reach the enormous weight of 330 lbs. A Gourd grown in Canada was exhibited last Christmas

at the Metropolitan Cattle Show weighing 313 lbs. We have also seen fine Gourds grown in woodlands where not overcrowded with timber trees, and planted the first season after cutting the underwood, particularly in sheltered valleys, where the land is moist and composed of vegetable mould, small mounds being formed, and manure or guano dug-in; in this way the plants have plenty of room, and are not encumbered with weeds, the underwood shoots shelter them and keep them in position.

#### WORK ON THE HOME FARM.

*Horse Labour.*—The work has been heavy lately, and where the animals have not had some Mangolds in addition to their usual dry food of Oats or Maize with hay they will, in some cases, have lost condition. One thing, however, is greatly in favour of the horses, and it should be carefully attended to—that is, the employment of steam power to perform the first cultivating or scarifying of the land deeply fallowed in the early winter. This should be done by the steam cultivator across the furrow at an acute angle first, and the second time it should be done across the first work. The land after being treated in that way is quite ready for the new self-acting drag-harrow made by Howards of Bedford, and by a couple of times with this implement; the land may then be rolled with the Cambridge ring roller, then two times with the iron harrows, and after being rolled the second time, and one time with the iron harrow, the chain harrow may be used with good effect. The land will then be ready to be cleared of the couch, of which there is on most of the fallows we have noticed lately a rather large quantity upon many farms owing to the wet seasons of 1878 and 1879. The practice generally is to burn it, but our plan has been for many years to burn only enough to furnish ashes sufficient to drill with the manure for the root crop. All couch in excess of that requirement we prefer to cart away to heap if we have no pasture land near which has been fed down close enough to lay out the couch upon, and spread as fast as laid out. In this way the succession of the grass on the pasture would be delayed only for a few days, and if chain-harrowed and rolled down there would spring up in about a fortnight a most abundant crop of grass. If, however, we have no land near in a fitting state to receive the dead couch we prefer to heap it, for we consider it unwise to burn any vegetable matters which will decay. The weather having been so fine during March and the first week of April, Barley sowing is now completed or ought to have been; if not, the sooner the better, and the same may be said of Potato planting. Sowing Mangold seed may be now commenced, and after it has been sown it will flourish regardless of weather if the land has been liberally manured either with yard or town dung. We prefer, however, artificial manures sown broadcast upon the surface, and then to throw two furrows together and drill or hand-dibble the seed upon the stretches thus formed, for the manure will be found just under the seed in readiness to act upon the young plant. Where the land works soft and fine stretching answers well, but where the land is rough and cloddy throwing two furrows together makes a poor seed bed.

*Hand Labour.*—At this time hand labour is a very important item of farm practice and expenditure, and will require all the attention and intelligence of the home farmer.

*Live Stock.*—The cattle and sheep, in most instances, have as yet passed through the period of scarcity of roots and green fodder better than was at one time anticipated, especially where feeding stuffs have been liberally supplied to them. In the cattle markets, which are again open, the sheep and lambs are in excellent condition when we consider the wretched weather which prevailed for several months. Sheep, too, come out of their wool in good condition and sell well in the London market; in fact, vendors of shorn sheep always find a worse market in the country when early shorn than they do in the metropolitan market. Much has been said lately about the slaughter of all stock sent to that market, and it is to be hoped that it will be made a standing rule from this time forward that no cattle or sheep be allowed to come out of London alive. We know from past experience that cattle and sheep purchased in London have generally done more towards spreading disease than has occurred in any other way, and especially we include the Deptford market for foreign stock, from whence the latest outbreak of foot-and-mouth disease spread into the country. We cannot see, even in the interest of the consumer, why the whole supply of foreign meat should not be imported dead, for under the present importations there is less loss and far less expense attending the dead meat than the live cattle importations. This is the time of year when the breeders of both sheep and cattle are selling their stock to the feeders in the pasture districts. We do not see the necessity of two parties being engaged in the breeding and fattening of stock, and the home farmer should consider the policy of breeding all the stock he requires for feeding, and by that means obtain not only all the profit from the two transactions, but also escape many losses. The home farmer in stocking the grass and parklands should also consider the policy of feeding the grass hard with sheep. It is, we know, common in good pastures to feed one bullock and one or two sheep on an acre—but why? We have asked this question of many business men, and have received but little reply, except that it is customary; but let it not be forgotten that the sheep will eat the best herbage, and thus injure the feeding value of the future produce.

#### VARIETIES.

*HOMING PIGEONS AS BIRDS OF WAR.*—Apart from the fact we have noticed on page 304, of the strange return to the old traditions and the consequent disappearance from our fowl lore of the 'gentle bird of peace,' there is a world of interest in this innovation of modern war. This pretty flying column without weapons may be so terribly powerful, and strike its blows so swiftly and invisibly, that, though telegraph wires may be cut, the shades of night prevent the working of the heliostat, and the vigilance of vedettes make the carriage of despatches impossible; yet, let the night be never so dark, and the enemy never so watchful, the news that may be their ruin will get through their lines. No sentries or battlements, no scouts or outpost duty, will be able to intercept the sudden messenger whose wings they hear passing overhead. Under that wing, fastened close by a silken thread, lies the little missive which may make all the difference between victory and defeat, which may betray tactics, encourage a wavering garrison to renewed resistance, or summon to the scene a shattering strength of reinforcements. All this, and more, may be hidden in the down of the Pigeon's under wing, and the enemy know it well, yet be powerless to prevent the bird from carrying over their lines to the beleaguered fortress, or to the head-quarters of the opposite camp, the news which they would give so much to intercept. A battalion of men could not carry what the one bird will; and thus resistless, it deserves to be ranked as a formidable feature in the adversary's equipment.

— *PROOFS OF AGRICULTURAL DISTRESS.*—Signs of the distressful agricultural times are plentiful. We hear of a market garden farm of 200 acres, not forty miles from London, the rent of which has recently been reduced from 22s. to 11s. per acre. An adjoining farm has been let on a seven-years lease, free for the first three years, while during the remainder of the term the rent will be 7s. per acre. Another large farm, with a good residence, is let for £70 a year, and the tenant re-lets the shooting for £60. In the midlands there is not the same inclination to let land for what it will fetch. Hence it is that 30,000 acres in Leicestershire are said to be still in hand. Rents in that county have been very high; and rather than let their farms at lower rates, landlords prefer to sell the crops and grass annually by auction at very uncertain prices.—(*Land.*)

— *THE Manchester Examiner* has published some extraordinary statements as to the reductions in the rents of agricultural land in the midland and southern counties, collected by a well-informed correspondent. It states that in Lincolnshire the rent of marsh land has fallen 30 or 40, and of clay land 40 or 50 per cent., while in the Fens many farms may be had by tenants who are ready to pay the rates and taxes. In Hunts the value of the fee simple of land has been reduced one-third. In Bedfordshire new lettings are from 25 to 75 per cent. under the old rates. In Essex rents have gone down by 40 or 50 per cent.

— A DAILY paper commenting on the above says:—"In some of the southern counties matters are still worse. In Wilts, for instance, on the northern edge of Salisbury Plain, a large portion of the farms are now unlet. On one estate all the tenants have left, and the land is now covered with grass and weeds; and on another estate some of the stiff land farms have been re-let, the first year rent free, and after that at less than half the former rent. The following are samples of the reductions on other estates:—A 1450 acres farm, from £1050 to £810; a 700 acres farm from £600 to £400. It is said that another 700 acre farm on a stiff soil has been recently let for £60 a year."

— *AGRICULTURE IN IRELAND.*—In the earlier parts the sowing of grain, and also the planting of Potatoes, are now almost finished. In many districts, partly owing to the abundance of last year's crop and to the low price of Potatoes, a larger quantity of them than usual has been planted. A correspondent in the south-west states that there many of the small tenants have planted a much greater breadth than in recent years, and most of these, he says, have used their own seed—Champions imported last year from Scotland. The sowing of grain, he says, is almost completed in some districts of the south-west, while the grass fields are looking extremely well; indeed, some well-sheltered fields are already affording good pasture to stock.

Fat stock are selling at very low prices, but for lean cattle there is a fair demand at satisfactory rates. Breeders of store stock will be interested, but not pleased, to learn that there is every prospect of large importations of Canadian and United States cattle during the coming season. An extensive English firm of salesmen state that they know for a fact that the shipments of Canadian and American cattle will be unprecedentedly large, especially in the early summer months.—(*Irish Farmers' Gazette*.)

— AMONG French farmers it is considered much better to give Beet or Mangold Wurtzel pulp to sheep and cattle for production of meat than for milk. Horses will not eat it readily. The daily rations of pulp given to sheep and cattle vary, but the amount generally considered most favourable are about 5 lbs. per head for sheep and 50 lbs. for cattle, in admixture with hay, seed cake, corn meal, or other food. The pulp is stored for preservation in trenches or silos, and for this purpose it is mixed with about 1 per cent. its weight of salt to prevent it from entering into putrefactive fermentation.

## POULTRY AND PIGEONS

### SEASONABLE HINTS.

We are now at what may be called the turn of the season, and a few hints as to general management may not be out of place.

First as to the old stock. Fanciers who have any intention of exhibiting at the summer shows will do well now to take a general look through their stock and select the most likely birds for the purpose. The breeding season is practically over, and the hens intended for show should be separated from the cocks. If in consequence of bad hatching, results which we fear have been too common this season, it is still necessary to set a few eggs from the best hens; their plumage can be protected from damage by merely allowing them to run with their mate for an hour each morning, and keeping them separate the rest of the day. With light-coloured birds and such of the darker ones as become tanned by exposure to the sun care must be taken that they are placed in the most shady houses. Any tendency to broodiness in the exhibition hens of the sitting varieties must be promptly checked, as the plumage becomes damaged and brittle by lying on the nest. Imprisoning the hens under an open wire coop placed on bare earth and giving an abundant supply of food are the best means of checking the clucking fever. If there be several cluckers, putting them all together will accelerate the cure.

In preparing Asiatics for exhibition at this season it is necessary to be cautious that the food given be not over-stimulating. Many a fine bird apparently in robust health one hour has been found dead the next from apoplexy, and any excess of stimulant accelerates, if it does not actually cause, attacks of this nature.

Next as to the chickens. Those who are fortunate enough to have a number of January chicks may now with advantage begin the process of weeding out the worthless birds. We cannot give any general directions as to this subject. Very much depends upon the breed and something also upon the strain, so that each young fancier must either call in the assistance of a more experienced friend or learn from experience which birds may with safety be disposed of. If space be at all limited merely in the weeding process is a mistake. It is better to kill one or two valuable birds than to run any risk of stunting all through overcrowding. Frequent changes of run, and if possible a move to a perfectly fresh run, do much to keep young birds in health and to stimulate growth. Where space will not allow of this, the frequent turning over of the soil and a liberal supply of green food will do something to replace the freedom of larger runs.

In the Spanish and Dorking breeds some of the chicks will now be at a critical period, when the rapid growth of feather causes a heavy drain upon their natural resources. In such cases the feeding will require special attention, and the addition of a little stimulant, such as bread soaked in ale, often has a most beneficial effect.

The older chickens must not be neglected for the younger, nor should they be all fed together, as this does not give the older birds sufficient time to get an appetite. The length of time between the meals must be gradually extended until birds which were fed every two hours at a fortnight old are reduced to four meals a day at the age of three months.

Lastly, a thorough weeding-out of the old birds must now be made, all those which are not likely to be wanted for breeding next season

being cleared out to make room for the youngsters. It is a bad time for selling, but it is better to take a smaller price now and get the birds out of the way than to keep them six months on the chance of getting a better offer. Beginners would do well to remember that a bad selling time is a good one for buying. Good birds which their owners would not sell except at very high prices early in the season may now be had at very moderate rates. In this way a fair start without too heavy an expenditure may be made on the suitability of a breed tentatively ascertained before actually taking it up.

### FOOD FOR CHICKENS.

THIS subject, like that of coops, is no new one, and we do not pretend to have discovered any new recipe for rearing every chick without fail. While, however, our system is old many of our readers are, we believe, young, or at least young in poultry breeding, and so at the risk of some repetition we will again give a few rules for the systematic management of chickens. To begin with, a chicken requires no food for from twenty-four to thirty-six hours after it emerges from the shell. Nature requires perfect rest for it under the hen, for during this time the development of some of its organs continues, and just before it bursts the shell enough yolk has passed into its stomach to provide temporary nourishment.

Novices sometimes cram young chickens, and thereby do much harm to them. Little or no trouble need be taken to make them eat, beyond giving them light and crumbly food that they can swallow and digest. For the first week or ten days chickens can hardly be fed too often, provided nothing is left about after each meal. Sour and trampled food disgusts them, and does more harm than a moderate amount of starving. The question is, What should this food be to begin with? Nothing is so light as chopped hard-boiled egg and bread crumbs, but if the weather is not severe we prefer dispensing with the egg. When chickens have such dainties there is always a difficulty in weaning them from them, and therefore, except in special cases, we always prefer at once beginning with what is to be their general diet. In our yards the staple of this is oatmeal. We were always struck with the vigour and hardihood of Highland children reared almost entirely on oatmeal, and so we adopted it for our chickens. Good Scotch oatmeal is boiled into porridge. That it should be properly boiled is most important. If too much is put to the amount of water, or if it is not properly stirred, good food can never be made from it; there will be heavy sticky lumps. The porridge should be made in the same way and with the same care as for human beings; kept in a cool place it will then be good for two days. As much as is required for each meal should be mixed with Indian meal, coarse barley meal, or occasionally bran, into a nice light crumbly food. This no chickens will refuse if given fresh and fresh, and on it our own have never failed to thrive. If the season be cold or inclement, instead of the plain oatmeal equal quantities of oatmeal and Spratt's food should be boiled together. Stimulants are sometimes necessary, but as a rule we find chickens fed on them, especially if there be meat in their composition, gain flesh at the expense of their bone and muscular strength. For the same reasons we suppose that human beings fed much on meat in their early days generally have bad teeth.

There is a constant controversy between those who give water to chickens and those who withhold it. After many experiments we have come to the conclusion that in winter they are better without it for a week or ten days, but then we give them bread and milk twice a day. Milk is a great bone-maker, and strengthens the constitutions of chickens amazingly. There are many apparently trifling cases which make much difference to the little creatures, among them is this—viz., that the bread and milk be properly made. The bread must first be thoroughly scalded in boiling water, the water strained off, and the milk poured on to it; they will then eat it with the utmost greediness and drink the milk as readily as kittens. For summer and late spring, chickens must from the first have more to drink, at least our own experience is that they soon droop if they have not. Milk left in the sun soon turns sour, so pure water is preferable, but a morning meal of bread and milk should be continued.

We are constantly asked, "How many times a day must young chickens be fed?" This depends on many things. In winter and the early spring when there is snow and frost and little or nothing to be picked up they should be fed six times a day, say twice with bread and milk, three times with oatmeal, and once with chopped house scraps, if such there are; the latter feed, even if it be but a minute one daily, makes a great difference in the progress of early chickens. At such a time of year they require all day to be kept in a state of repletion to make up

for exhaustion from cold and the long nights; when warm weather comes and the broods are running over grass for twelve hours a day even the youngest will do four or five feeds a day. It is better for them to have to hunt for some of their provender, and constant exercise prevents them outgrowing the strength of their legs. When chickens are ten days old they may begin to have a last feed in the evening of groats or small Wheat; these digest slowly, and give warmth through the night; they must, however, be distributed with judgment—far better not at all than in indiscriminate quantity. Careless people often give chickens enough to gorge themselves, at the same time leaving their drinking pans empty; the result is too often that their crops are strained by the mass of hard swelling food and burst, or become permanently loose. Up to three months old all young birds, whether intended for the table or for exhibition or breeding stock, should be fed regularly four times a day. Henceforth three good feeds will suffice. It should be remembered that when the bird is destined for the spit as soon as ever ready no harm will be done by forcing it a little—i.e., it may be more frequently fed, and some of the many stimulating foods now sold may be mixed with the oatmeal. Where, however, the strength of constitution and eventual size is desired, then the system we have described will be found effectual.—C.

#### NOTES ON HATCHING.

THIS is a subject in which every poultry-keeper is interested at the present time. Since incubators have been so much written about, it is very seldom we see anything upon the old-fashioned way of hatching with hens; but this is still by far the most common way of securing young chicks, and is likely to remain so until incubators become much more reasonable in price than they are at present. Unless it is a second-handed machine that may sometimes be advertised cheap, incubators alone cannot be bought for less than £5, and apart from this there come the necessary additions in the way of drying nests, indoor rearers, outdoor rearers, thermometers, &c., which cannot be obtained for much less than £10. Those who keep poultry solely for pleasure may not object to expenditure of this kind, but those who study the profit question—and the great majority do this—will, I am sure, continue to utilise their broody hens for hatching. It is certainly the most profitable purpose to which fowls in that state can be applied, and they are always safe and little trouble.

Early layers are always early sitters, and those who want broody hens in January and February can generally manage it by hatching early, feeding well in the autumn, and keeping them in warmish quarters to induce them to lay. A quiet nest with a few dummy eggs in it are useful in such cases. There is no difficulty in having broody hens from the end of January onwards. It is always best to allow old hens to sit and settle a few days before putting the eggs under them. From the first they should be in the nest they are going to sit in. Baskets, boxes, or places made for the purpose will do. Too much space should not be given, enough for the hen to sit comfortably is all that is wanted. If the entrance to the nest can be closed so much the better. Some advocate having the nest on the ground, others some distance from it, but I have had as fine hatches from the box nests 4 feet from the ground as from the level. The place should be cool, not over-draughty, and the ground should always be moist. I do not approve of trusting valuable eggs in woods or outside confined quarters, as foxes are always prowling about.

It is often asked, At what age are eggs too old for hatching? Not older than ten days, many will say; but I do not agree with this altogether. I have had old hens which laid away in the woods return with as many as sixteen chicks, proving, I think, that the oldest of the eggs must have been at least upwards of three weeks old. The game-keeper here, who hatches out annually about 1500 Pheasants with hens, tells me that sometimes they sit eggs a month old, and they appear to be little or no way inferior to the freshest. Providing they have been kept in a cool place, I think eggs would be quite fertile at the end of twenty days. When eggs are fresh and hens ready, there is no reason why they should be kept so long. Sometimes, however, it is necessary to keep them for want of hens, and it may be convenient to know how long they will remain good. The fresher the eggs are, the sooner do they hatch. Sometimes when I have put a dozen under a hen, some of them being ten days old, and others hardly cold after being laid, I have found the latter hatch out at the end of the nineteenth and twentieth days, while the old ones barely came out on the twenty-first day; and this is not desirable, as much difference often leads to the loss of the last chicks. No brood is ever better than when all the chicks come out within an hour or so of each other, and this can easily be secured by paying attention to having the eggs all as near the same age as possible.

With young beginners broody hens are often liable to be over-attended during the time they are sitting. The less they are disturbed the better. Once a day ours are fed and watered, and after that they are never looked at again until the following morning. They are fed on grain only. In connection with this there is another question which often leads to much doubt, and this is as to what time the hen should remain off the nest. Young pullets will often rush back to it after being only a few minutes off, others will stay away for half an hour or more. In the one case are the eggs over-hatched, or in the other are they sufficiently so? To the first question we answer No, to the second Yes. So long as they do not remain off more than half an hour we never feel alarmed, and if they do go back at the end of the first five minutes it is just the same. Some little difference this may probably make, but I can say it is neither seen or felt in practice. As a rule our hens remain off their nests about fifteen minutes.

If those who have many unfertile eggs would look to the condition of their male birds an alteration might be effected. During the time hatching is taking place I never remove the hen or allow her to leave the nest, although it is seldom they wish to do so at such a time. The chicks should be left under the hen to become dry for some hours before removing them. The very best start young chickens can receive in life is to be thoroughly dried under the hen. I have seen many young chicks die before they were many days old through disturbing them and the hen too soon. Healthy chicks will soon let anyone know when it is time to bring them food, as they quickly show their little heads from under the breast of the hen when they are able to bear exposure. When removed from the nest altogether they should have dry ashes or sand placed in their run, and for the first fortnight or more they cannot be kept too much before the sun or too much away from cold winds. Lately I have had some young chicks doing remarkably well in Cucumber frames.—M. M.

#### OUR LETTER BOX.

**Pheasants not Hatching** (*A Poultry Fancier*).—Pheasants' eggs hatch badly for the same reason that hens' eggs do so—viz., the extreme dryness of the atmosphere and parching winds. They should, if possible, be set in a damp place; a week before they are due to hatch be put for twenty minutes into warm water, and again two days before they are due. The nest may also during the last week be daily sprinkled through a rose.

**Coloured Dorkings**.—A correspondent wishes to purchase fertile eggs of a good strain of this breed. Those who have eggs for disposal should advertise them.

**Chickens not Hatching** (*F. Jones*).—It is not uncommon at this time of year, especially after such cold dry winds as we have had, for eggs to hatch two or three days after their time. This is often the case, too, if they have had a chill from the hen remaining off too long. We think you certainly did wrong in cracking the eggs. If they had been left alone they would probably have hatched properly, and the chickens have been stronger. As to their being unable to stand, no chicken can stand the moment it has left the egg. Black Spanish always hatch with white breasts and white in the wings as you describe.

**Thousand-Headed Kale** (*North Wills*).—It is very productive and hardy. The seed should be sown now, and the plants when large enough planted 2 feet apart in rows 3 feet asunder. It is valuable for ewes and lambs, as many shepherds have found who have been fortunate enough to have a supply of it during the present inclement spring.

#### REMARKS.

10th.—Not so bright as previous days; but less wind and warmer.

11th.—Overcast and slight rain in forenoon; afternoon bright.

12th.—Cloudy, with sunshine and slight showers at intervals.

13th.—Very fine, bright, and warm.

14th.—Mild, slight showers; foggy at first.

15th.—Hazy early, afterwards fine and bright; few drops of rain 5.30 P.M.

16th.—Fair, but not very bright.

Nearly 10° warmer than last week, and considerably above the average; barometer steady, and rain slight.—G. J. SYMONS.

### PEACH CULTIVATION UNDER GLASS.

**M**UCH has been written lately of the various methods adopted in the cultivation of the Peach under glass. The different systems of planting, pruning, and training have been freely discussed in the gardening papers: some writers preferring one method, and some others, as the case may be. The method of planting generally practised in large gardens where there is a great demand for fruit, is to plant so that the trees when trained will cover the entire roof of the house. In span-roofed houses the trees are planted close to the side walls, and in lean-to's close to the front wall, and trained in fan-shape to a trellis at a sufficient distance from the glass. I prefer this system of growing and training the Peach to all others, as the trees have the full advantage of being exposed to all the light and sunshine possible to ripen the fruit and wood. Having had considerable experience in the cultivation of the Peach, I venture to say that more fruit can be produced from trees planted in a house and trained on this system, and of better quality too, than can be produced from any other method of planting and training.

Good fruit may be grown both on cross trellises, back walls, and on the old-fashioned turned-over trellis in front of the house, but not with results equal to trees trained on a trellis close to the glass and properly managed. In proof of this assertion I might state that I planted a house here some six years since, a lean-to, 60 feet long, 14 feet wide, and 16 feet high, with a tree each of the following four varieties—Belle-garde, Royal George, Noblesse, and Barrington. The trees were young, clean, and vigorous, and had at the time of planting from three to five well-ripened shoots each of one year's growth. The shoots were left their full length, and tied to the trellis just as they came from the nursery. They started well, and by the end of the first year's growth they had more than trebled their number of well-ripened shoots, and in three years from the time of planting the trees covered the whole roof and finished-off a crop of no less than 112 dozen fine Peaches. I planted trees in another house some twelve years since, which came into full bearing four years after being planted, and have continued to bear heavy crops of the best quality ever since.

I grow the Peach on what is now called the extension system. Is the system really new to the majority of gardeners in this country? The name I admit is new to me, but not the system. I have not cut or shortened the point of a Peach shoot (as a rule) for more than twenty years. I do not, how-

ever, allow the laterals to grow any more than I do those of a Vine. They are stopped as soon as they appear, and never allowed to make much headway; and in this only does the system differ, as they are allowed to grow on what is called the extension system. As a matter of fact I can always get plenty of good shoots to fill the house without having recourse to the laterals. I make no claim of being the originator of the "new system," though I have practised it in a modified form (taking off the laterals), for more than twenty years. I could name several who have practised it for nearly fifty years, and yet it appears as a system but little known to gardeners in this country.

The last place I worked at as a young man, where the shoots were shortened or cut back to what was thought a treble bud and practised regularly, was Drumlanrig, and the first place I ever saw the shoots of a year's growth left entire at pruning time was practised at Stoke Farm near Slough by Mr. A. Simpson, and I am sure the system was not an original idea of his, at least he never said so. I have practised it ever since both in England and Scotland, and now, some twenty-three or twenty-four years after, I am amused to find it is comparatively new to many, and thought to be a new discovery by some.—A. PETTIGREW, *Castle Gardens, Cardiff*.

### BALSAM CULTURE.

My experience on this matter has been gained from a good practitioner of the old school of gardeners. His method was most successful; and although I live in a neighbourhood of good gardening, I have never seen Balsams like the magnificent specimens he produced twenty years ago. There is a great danger, especially among young gardeners, of despising plants which are cheap and which can be produced for a small outlay of labour and care. For this reason Balsams are grown by a few, and those few very often grow them badly. The expenditure of a shilling and the exercise of a little care will produce plants worthy to be staged in any conservatory. The first consideration is to procure good seed. If possible let the seed be English-saved, as foreign seed is often too cheap to be good. Any respectable seedsman will supply a packet of the best Balsam seed for 1s.

The compost in which the seed is to be sown should be somewhat similar to that used for Pelargoniums. Small pots should be employed half full of the compost, and two seeds should be sown in each pot. The pots should be placed in a gentle hotbed close to the glass, and when the seedlings appear the weaker in each pot should be drawn out and the stronger allowed to grow. When the seedlings are tall enough the pot should be filled to the rim, this encourages the young plants to form abundance of roots. The plants should be potted as soon as the roots are plentiful into the next size, say a 4-inch pot, still keeping them in the frame. They may be successively shifted on until they are in the pots in which they are to bloom, taking care at every potting that the soil is up to the seed leaves. If it is desired to have very large specimens the first flowers should be removed to encourage growth and the formation of side shoots. As the plants grow they must be taken from the frame.

The material used by my old friend in the later pottings was as follows:—Two barrowfuls of well-decayed manure and one barrowful of good loam thrown on to the floor, chopped and mixed with the spade. This material was used very

"lumpy," and never failed to produce luxuriantly growing specimens full of health and beauty. The Balsam delights in a moist heat and a very slight shade. When coming into bloom it will be benefited by copious supplies of liquid manure. The structure in which the Balsams to which I have referred were grown was a large vinery, and they succeeded admirably in their position. The seed may be sown now. Very fair decorative plants may be produced in eight weeks from the time of sowing seed. From this it will be seen how convenient it would be to sow seed so as to have a batch of plants to occupy the places vacated by the bedding plants. Few know what a large size pot the Balsam will take; as a matter of convenience, however, a pot 9 inches in diameter will be most suitable for flowering the plants in.—VINCE.

#### RAISING RHUBARB FROM SEED.

WHEN your correspondent "PRACTICALIST" informs the readers of the Journal that "raising new plants from seed is a better way of obtaining fresh stock for a new plantation than dividing the old roots," he must not expect all gardeners to agree with him. I know well how readily plants can be raised from seed, and with less trouble than by the mode described on page 288, but I do not know how it is possible from a purchased packet of seed to carry out the excellent principle of "only growing a good variety or two which always give most satisfaction," such as "St. Martin's and Albert." Will "PRACTICALIST" tell us how many plants of these varieties he has obtained from a packet of purchased seed, and how many that differed from them? True, he tells us that those who experience difficulty in obtaining pure seed should raise their own. But how much time will be lost in proving the purity of the seed? If there were any difficulty in increasing the stock of Rhubarb, of which satisfactory varieties are established, then the plan of raising plants from seeds might be adopted; but most gardeners, I think, can turn their glass structures to better account than by occupying space in the manner suggested. If your correspondent cannot grow good Rhubarb without having recourse to the elaborate practice that he has described he would not be considered a first-rate kitchen gardener by at least a large majority of cultivators and their employers. After having tried the system of raising Rhubarb from seed and seen it tried by others, I and they have fallen back on the "old lines," and we find we can really maintain a supply of the most satisfactory produce from a few superior varieties, which we contrive to keep distinct by dividing the crowns.

For the information of those who desire to grow Rhubarb from seed, and who have no suitable glass structures for raising the plants, it may perhaps be useful to state that good seed will germinate freely if sown like Parsnip seed in the open ground, but in May instead of in March. It also grows freely if sown as soon as gathered, forming small plants the same season, which the following year will be quite as fine as those "raised in heat and hardened off before planting," as if they were so many Castor-oil plants.—A PLAIN GARDENER.

#### ACHIMENES FROM CUTTINGS—WRITING TO THE PRESS.

MR. WM. TAYLOR'S remarks on page 269 lead me to say that I have for many years grown these plants from cuttings, and so have some of my gardening friends. The cuttings are inserted in pots three parts filled with soil, the top inch being nearly all sand, the bottom inch all manure, and the bulk a mixture of loam and manure. A square of glass is placed over each pot, which the tops of the cuttings nearly but not quite touch. A brisk temperature, regular moisture, and shade for a week are the chief essentials for success. I have found the cuttings strike readily in a Cucumber pit. As the plants are required in 6 and 7-inch pots the cuttings are inserted an inch apart in pots of that size, and after the plants have commenced growing freely a rich compost such as loam and dried cow manure or the refuse from a Mushroom bed is placed amongst them, a few of the lower leaves being removed so that it comes in contact with the stems. From these roots are emitted freely and the plants then grow rapidly. They are dwarfer than plants grown from tubers, and apparently more floriferous, and being grown in rich soil the flowers are as fine as can be desired. In lighter soil containing a large proportion of peat the plants grow rapidly in their early stages, but there is not sufficient sustaining power in it to produce luxuriant specimens with rich foliage and fine flowers for a long period. The finest plants I ever had were grown in a mixture of equal portions of

burnt clay and the remains of an old Mushroom bed; and I may add incidentally I never had Maidenhair Ferns, *Adiantum cucullatum*, and others so fine as when grown in that mixture. More care is required in watering Achimenes when they are grown in strong rich soil than in a lighter compost; but water being judiciously applied the plants enjoy this liberal fare.

For anything I know to the contrary Achimenes may have been grown from cuttings before I knew what a cutting was. Be this as it may, I found by an accident that the cuttings would strike readily enough; for some plants having been topped and the portions thrown on the tan in a Pine stove, some that were shaded rooted into the tan. The practice of growing the plants was not adopted for some time afterwards, and was then brought about by a more serious accident than the foregoing. The tubers of the stock were at rest in a place to which the frost found access, and all were killed. A dozen plants were bought in the spring, or rather a dozen varieties, for there were three small plants of each in each small pot. In due time the plants were topped and the cuttings struck, and by the autumn a far more satisfactory display was produced than if this mode of increase had not been adopted. I found, however, that the cuttings struck late did not produce such fine tubers as those from the original plants.

Mr. Taylor's remarks on writing to the press are timely. When I was a young man I hesitated long before venturing to send my remarks to that terrible man—an editor, and almost trembled at my temerity after my first missive was despatched; but I eventually found a great amount of human nature, even brotherly kindness, might centre in those erudite and to my then youthful mind mysterious individuals. From more than one of them I have since had encouragement which proved directly to my advantage, as my writings being accepted urged me to closer work and study, for I felt I had won a "position," and must not only maintain but improve it, and so became a better gardener and ready when an opportunity occurred to step from a small place to a large one.

My first communications were of course "spoiled" in my esteem by the editor who appeared to take out all the "best bits," all the smart hits, all the most laboured and elaborate sentences. For a time this editor was a perfect enigma to me. I could not understand it. I tried another, and yet a third, and they both did the same; at length as time rolled on it occurred to me that these inexorable censors could not "mutilate" my work from sheer wantonness, but must have some substantial reason for their practice. Eventually it began to dawn on me (I was getting older then), that they might be as good judges of writing as myself, and might even know better than me what it was prudent to admit and what to reject of my elaborate communications. I have long since been satisfied that such was undoubtedly the case, and I am sure they prevented the appearance of much of my youthful nonsense, false science (if there is such a thing), affected expressions, grandiloquent sentences, and "sly pokes" at something or somebody that it would not have been prudent to have published. In this respect I have no doubt escaped many a literary wiggling that I should have incurred, and thus, what I once thought cruel was in reality kind. I have found that editors protect young writers and do not expose their failings, and that what these gentlemen want from gardeners such as myself is plain practice and plain Saxon. I daresay they do not object to a "bit of science," but I do know that there are very few young gardeners able to take "safe flights" in this direction. Let them study science, but leave others of maturer years and with special attainments to expound it.

A gentle rebuke I received many years ago may perhaps be mentioned. Being engaged in planting Box edging I was impelled to write about it. Thinking the subject a very commonplace one I hunted up some particulars about the history of Box, its nature and components, and fancy I copied something from an old book, and so in my vanity made up a "fine article." A few days afterwards the bulk of my paper was returned to me, only a small portion being retained. I was favoured also with a short note as follows:—"You appear to understand Box planting, and no doubt your edgings are level, firm, and straight: others need such information as you are competent to give, and your notes on this subject will appear. The matter returned is in advance of the wants of our readers; place it in your desk for five years, then read it, and if you still think it can be usefully published send it to us again." I daresay the shrewd editor knew that in that time I should be ashamed of my work, and he would never see it again, and he was right.

Ever since then I have endeavoured to state plain facts and narrate simple experience in a manner that I hoped might be easily understood and prove useful, just as I wrote about planting Box edging about thirty years ago, and just as I have described

growing Achimenes from cuttings now; and as the first found acceptance so I assume will the last; and no doubt if the same matter had been sent by a young man of twenty who could scarcely curl his moustache, it would have been as readily printed as it will be from one who can remember when Buonaparte's name ("old Boney") was a terror to schoolboys, and one who has grown grey in the work of his life—gardening.—AN OLD HAND.

#### MR. WHITTAKER'S CUCUMBER HOUSE.

ONE of your correspondents desires information as to the motive Mr. Whittaker had in building his new house such a great length (197 yards) in preference to several smaller ones. Mr. Whittaker, while declining to enter into any controversy on the subject, informs me that he finds it much easier and cheaper to work in proportion than his smaller houses, although they probably are from 100 to 150 feet in length. I believe in the first instance it was built in its present form to utilise an existing wall and building materials in an economical manner. A tramway extends the whole length, on which runs an iron tank containing about a ton of water, which can be easily moved along, so that the watering or damping can be done very expeditiously, and the tank can be quickly filled at any of the eight wells in the house. It also provides an easy conveyance for soil, and the Cucumbers are when cut also easily removed. It is most peculiar to look down that great length, the trellises being covered to within 18 inches of the ridge with luxuriant growth, towards the bottom abundance of fine fruit ready for cutting, higher up the countless blossoms almost appear when looking down a sheet of yellow.

I daresay there are several points to which many cultivators would take exception; for instance, the entire absence of ventilators, also no vapour troughs are employed in any of the houses, and no laps in glazing; but the squares fit very true, and with the condensed moisture which will lodge between the edges of the glass the houses must be nearly airtight. I believe Mr. Whittaker ignores shading even in the brightest weather. These are points that may cause some speculation, but "nothing succeeds like success," and that Mr. Whittaker is a most successful Cucumber grower nobody can deny. Besides Cucumbers immense quantities of Mint and Rhubarb are well grown, with many thousands of plants in pots. I may add that the great house and most of the others are span-roofed, and most efficiently heated with Mee's saddle boilers with hollow bars, waterway back, and front plate. Two 6-foot boilers are employed for the large house.—J. J., Lancashire.

#### ROSE SHOW FIXTURES.

AS far as I have been able to ascertain, the following are the fixtures for Rose shows for the present season. There are others, such as Hereford and Oxford, of which I have not heard as yet.

June 28th .. .. .	Royal Horticultural Society.
June 29th .. .. .	Farningham.
June 30th .. .. .	Canterbury.
June 30th .. .. .	Farnham.
July 2nd .. .. .	National Rose Society, Crystal Palace.
July 4th .. .. .	Maidstone.
July 5th .. .. .	Reigate.
July 6th .. .. .	Cardiff.
July 7th .. .. .	Horsham.
July 7th .. .. .	Norwich.
July 8th and 9th .. .. .	Alexandra Palace.
July 9th .. .. .	Brockham.
July 14th .. .. .	National Rose Society, Sheffield.
July 15th .. .. .	Galloway.
July 16th .. .. .	Wirral.
July 17th .. .. .	Leek.
July 22nd .. .. .	Sutton Coldfield.
July 29th .. .. .	Helensburgh.

There is one of these fixtures to which I would wish to draw especial attention—that at the Alexandra Palace, which it will be seen is a two-days Show, and concerning which I received a letter from one of our oldest Rose-exhibitors pointing out the expense and inconvenience that it was, and asking me to endeavour to effect an alteration. I wrote to my friend Mr. Forsyth Johnson, the able Director of the flower shows, but I am sorry to say without effect. It therefore stands as the only case of a Rose Show *pur et simple* where the abomination of a second day's exhibition of dragged and forlorn Roses is to be seen; and I would draw the attention of such Rose-exhibitors as are members of the National Rose Society to the fact that when the Society was started one of its objects was expressly stated that it was to discountenance by every means in its power two-days Rose shows, as these were beginning to be the rule. We as a Society have all through steadily maintained our rule. We have had to fight a very hard fight in our provincial shows to maintain this principle, and surely the members of the Society will feel bound in honour to resist the

temptation to depart from what they have elsewhere maintained. If they give way to the temptation here it will be offering a bribe to other places to do the same, and we shall then be getting back to that from which we have delivered ourselves. I have suggested to the friend who wrote to me that a round robin should be signed by those who intend to be exhibitors that they will not exhibit if the two-days show is persisted in. If there are no exhibitors there can be no show, and the proprietors and managers are too shrewd to hold out if the expressed determination of the principal Rose-growers is made known to them. It will be necessary if this is done that there should be a very general concurrence, for if the thing be not well done it will be fruitless; but "a strong pull, a long pull, and a pull all together," and the attempt will be effectually quashed.—D., Deal.

#### HYACINTHS AND TULIPS IN HYDE PARK.

THE masses of Hyacinths, Tulips, &c., which extend from the Grosvenor Gate and the Marble Arch in Hyde Park, and which annually afford a beautiful display, are now at their best. A charming effect is produced by the large beds of red, white, and blue Hyacinths which are here so prettily grouped; and though the cold winds of the last few days have in some cases impaired their appearance, in no other public enclosure in the neighbourhood of London are these flowers cultivated with greater success than in this Park, and they cannot but give the utmost satisfaction to the public. Each of the beds contains only one variety, and the bulbs are planted about 9 inches apart. Among the varieties represented are, *Red*—Norma, Amy, and Robert Steiger. Of these the latter, of which there are several splendid beds, is far the most effective. Nothing could be more glowing and beautiful than are the beds of this well-known variety; it is a very bright crimson, and its dwarf sturdy growth and close compact spikes of bloom compare favourably with the thin and loose appearance presented by Norma. *Blue*—Charles Dickens, a fine variety, of which there are several good beds; Regulus, a dwarf pale blue, very largely grown there, and an excellent bedder; Blondin, a well-known variety, but not so attractive as Regulus, from which it differs in being less compact; Orondates, a compact Hyacinth of good colour and a very useful bedder. Uncle Tom and William I. are also represented, but compared with their lighter-coloured rivals they present a very poor appearance. *White*—Grand Vainqueur, large, pure white; one of the best varieties grown. It is represented in two or three beds, and presents some of the most effective massing in the entire group. Sturdy and compact, it contrasts finely with the glowing crimson of Robert Steiger and the bright blue of Charles Dickens. Mirandolina is also a pure white of excellent effect, and little inferior to Grand Vainqueur. Grandeur à Merveille, blush white, is very large; a well-known and useful variety, but scarcely so imposing as the two former. La Candeur is also grown, but is much inferior to the other whites, being rather small and thin. There are also one or two large beds of Sir E. Landseer, a very dwarf and effective Hyacinth of somewhat singular colour, being a deep coppery lilac. A good dark blue is wanting, and Baron Van Tuyl is suggested as an excellent bedder.

Among the Tulips are included beds of such well-known beautiful varieties as Rose Grisdelin, rose and white, a very pretty flower; Yellow Prince, a fine dwarf, rich yellow, of good effect; White Pottbakker and Comte de Mirabeau, whites—both good and attractive varieties, the former being exceptionally fine; Joost Van Vondel, crimson, a dwarf and pretty flower; Brutus, dwarf crimson; Keyzers Kroon, a well-known large and showy Tulip; Duchess of Austria; and doubles Tournesol and Gloria Solis. All the above are good bedding varieties, and planted 6 inches apart in large beds they have an exceedingly fine appearance. The bulbs employed there, also those in the Regent's, Victoria, and Battersea Parks, were, I am informed, supplied by Messrs. James Veitch & Sons, whose collections of Hyacinths exhibited at the spring shows of the Royal Horticultural and Royal Botanic Societies recently attracted such great attention.—P.

MARÉCHAL NIEL ROSE.—For some weeks I have been much interested with the letters that appeared in the Journal on the Maréchal Niel Rose on its own roots *versus* on Manetti or Briar stocks. Perhaps I may add my experience. In the autumn of 1878 I purchased a Maréchal Niel on its own roots from a cutting struck the same summer. It was planted in the centre of the greenhouse; it grew vigorously; and in the following spring had a good supply of flowers. During the summer the plant extended so much that I found it would prevent my attending properly to my Vines, so I replanted it against the back wall of the greenhouse, using for a compost good loam with a fair sprink-

ling of ground bones, old mortar, and a little soot. Last season it grew well but did not bloom. This year I have been cutting flowers for the last month, and shall have a good supply for some weeks. The plant is producing strong shoots, and after the flowering is past I shall cut it well back, and no doubt by the autumn it will have extended the full length of the wall.—AMATEUR, *North Lancashire.*

## THE EFFECTS OF ELECTRICITY ON VEGETATION.

(Continued from page 270.)

**VENTILATION.**—Many years back, and long before there were "greenhouses for the million," we were desirous of having erected a small plant house to serve as a greenhouse and conservatory, as well as a kind of porch to a south doorway opening from the hall into a small garden; but the difficulty was to find someone to undertake the construction who seemed equal to the occasion, and therefore information had to be sought from practical gardeners as to the requirements, and the only thing they all agreed in was that there must be "plenty of ventilation." Acting on this advice, in a small house (12 feet by 14) there were no less than eleven sashes hung for opening, so as to have the opportunity of trying all aspects and to almost any degree. This, however, was soon found to be all a mistake and worse than useless. Without enumerating all the failures, it will be sufficient to state that after innumerable trials a principle was hit on that has been working for many years with the most complete success. On reflection it will be seen that the air or wind never blows down vertically upon plants and trees, but that it always strikes at an angle sideways. Now any opening in the roof under the pretence of letting out the heated air is just what I hold it does not do, but it lets in a mass of cold air in an unnatural direction upon the plants. The only way in which the heated air can be let out in this position is by dividing the area of the opening midway, so that cold air may come down on one side of the partition and force up the hot air on the other side; but this does not obviate the former evil. In order, therefore, to fall in with Nature's arrangements a large sash was made to open immediately under the apex of the half-span roof at both ends, east and west, and these sashes were hung at the lower edge so as to open at the top outwards. By this provision the hot air would naturally escape immediately under the ridge of the roof, whilst the colder air would roll down over the inclined sash and thus acquire a slanting direction into the house, and at the same time be mollified by admixture with the warmer air met with in its passage downwards. The extent of ventilation will necessarily be regulated by the condition of the external surrounding atmosphere. What will do in one situation may fail in another, but this same principle of direction will apply in all. It has been observed that plants require to absorb moisture and carbonic acid from the atmosphere, hence it is essential that a due proportion of these should always be present. Surrounded by buildings, the dry walls rob the air of its moisture and impoverish its nutritive qualities, in this way rendering it unsuitable for ventilation; therefore an elevated point of admission is far preferable to others lower down, whilst the deficiency of moisture may be more easily made up by syringing below.

In the open country the surrounding vegetation keeps the air moist and genial, whilst the necessary carbonic acid is abundantly supplied by all fermenting and decaying organic matter. Now, as the air parts with its moisture, its oxygen, and its carbonic acid, and becomes exhausted, its removal to make room for a successive supply fully charged is one of the intentions of ventilation. In animal life this is provided for in a special direction; the expired air charged with warmth and moisture is thereby rendered lighter than the colder and drier air to be inhaled, and hence it ascends in the atmosphere immediately on escaping, and so leaves the fresh air uncontaminated below it. Not so, however, with plants; its removal and replacement can only be effected by the wind or motion of the air. It is desirable, too, that although rapidity of change may be advantageous, it is highly important to avoid all cold and cutting draughts.

In the Mushroom pit it is equally important that there should not be sufficient ventilation to disturb the negative stratum of air necessary for the fructification of the fungus. On the other hand, in the fruit room it is a consideration to obtain a free circulation of the positive atmosphere in order to dispel any negative stagnation overlying and enveloping the fruit that might induce mouldiness. In mildew one of the primary conditions is want of polar energy, which may arise from dryness or an unequal supply of moisture to the roots. In the case of pot plants standing on pans of wet cinder ashes will be found an excellent proceeding, whilst for Roses, &c., planted out drain pipes choked at the lower

end and sunk among their roots here and there and kept full of water in dry weather will prove serviceable feeders. In vineries and plant houses it is notorious that mildew occurs chiefly in the night, and that it is almost certain to occur in the autumn when roof windows are left open during the darkness; but with the upper end opening my own experience has shown that it rarely if ever occurs. It must, however, be observed that it is only the east window that is ever left "air on," and this has arisen entirely from direct experiment; but why this aspect in preference to any other, may seem a puzzling question. It must have been felt by the generality of practical men that extremely minute and subtle changes have great influence in promoting health or disease, and therefore they will necessarily be prepared for any announcement of the existence of apparently most insignificant matters provided as means to an end. Now, as the sun's rays have a very marked influence upon the atmosphere through which they pass, and upon the vegetation they impinge upon, the direction in which the rays fall will naturally be of no slight consequence, and hence the way they are met will of course be of some considerable importance, as we see by certain leaves always directing one particular surface sunwards. The apparent motion of the sun from east to west being caused by the real motion, or revolving of the earth on its own axis in the opposite direction—namely, from west to east, places the eastern or south-eastern side of a house in the position up to noon of meeting the advancing rays; but after that, when the sun has passed the meridian, the western and south-western side will be running away from the receding rays as they incline towards the setting in the western horizon. Hence, air admitted to a house or frame on the eastern side will be that which has received the latest benefit of the sun's rays; but it must not be confounded with the wind or air's current, as these are as perfectly distinct as the motion of a running stream from the wave motion upon its surface, and must be admitted through spaces proportioned to its intensity. A small house erected for containing a dozen Tea Roses had at first only an east window, but fancying more air might be advantageous a west window was introduced, and this was the commencement of the appearance of mildew. It was then closed and the plants sulphured, when the mildew disappeared and has never since reappeared, although the east window has been left open night and day up to the present frost. The same result has been obtained in the city conservatory; but whether peculiar circumstances may in either case have had influence, or whether the principle applies generally, remains to be proved, and which is well worthy of attention. Then, again, there is one other significant feature that has as yet never received attention—glass being an electric, which means that it is a non-conductor of electricity and hence acts as an insulator, and thereby separates electrically the confined air of a house or frame from the electricity of the atmosphere surrounding it, as well as itself becoming charged with electricity. These facts enlighten us as to the action of glass frames and other coverings hitherto unrecognised.—W. K. BRIDGMAN.

## A PLEA FOR ANNUALS.

ON a future occasion it is intended to direct attention to some of the best hardy herbaceous and alpine plants for garden decoration, but in the meantime the advisability of cultivating annuals more freely is strongly urged, special emphasis being laid on the word "cultivating," as in many instances these plants are not cultivated but starved. They are worthy of a better fate, as they produce shades of colour that are not obtainable in any other flowers.

We have frequently been told when arguing the claims of annuals "that the plants are very pretty while they last, but their flowering season is so brief that they are scarcely worth the trouble of growing them, especially as they leave the borders blank and dreary, besides causing them to present an untidy appearance when the plants are fading." These statements are to some extent true, but that they are so is not so much the fault of the annuals as of those who grow them. What would be said of a gardener who, to keep up a succession of any vegetable, say Peas, only made one sowing? He certainly would not be called a model kitchen gardener. What, then, can we say of those having flower borders which they wish to be kept gay with annuals who only make one sowing, and because the plants do not continue flowering throughout the season discard them altogether?

Annuals are charming additions to a flower border if a succession of sowings are made. Some kinds require to be sown in the autumn, as the spring-sown seeds do not produce such fine flowers, whilst many of the autumn-sown plants will survive and help to produce a brilliant display in early spring.

To prolong the time of flowering these plants should have every capsule removed immediately the flower fades or falls; this throws the strength of the plant into the remaining flowers and buds, and consequently the plant maintains its vigour to the last. If the successive sowings have been made judiciously no untidiness need be seen in the borders, as the second sowing will commence

flowering before the first is quite past, and thus the former can be removed without creating a blank or remaining sufficiently long to become untidy. It is impossible to make any rule respecting the sowing of annuals which shall be infallible, but species which will live through the winter should be sown from about the middle of August to the middle of October, according

Fig. 76.—AUTUMN-SOWN CLARKIA.

to the particular part of the country in which the reader may reside. These will commence blooming in March and April, when another sowing should be made as a succession crop, and again about the beginning of June for a third. How beautiful annuals are when sown in the autumn may be seen by the accompanying engraving of a spray of Clarkia (fig. 76) that was

cut from a plant now flowering in a pot in a greenhouse, and many others equally fine will shortly be flowering out of doors.

By the manner in which annuals are usually treated one would suppose these plants differ from all others, and require to be grown as closely together as possible; on the contrary, however, nothing can be more erroneous, as liberal thinning will speedily

convince any of your readers who have any doubts on the matter. Indeed if a score of plants have to live in a space only sufficient to maintain half a dozen, the result must be starvation. In sowing annuals, if the natural soil of the borders is either too heavy or too sandy, it is best to sow in pans or boxes and transplant into the borders in some prepared soil, which for most kinds should incline to the side of lightness, and at the same time be open and moderately rich. Of course the half-hardy kinds must have protection, and we know of nothing more suitable for this purpose than an ordinary dung frame, which should have lost its rank heat before the sowings are made. The young plants, however, should not long remain in this place, but be pricked out into pots and placed in a sheltered position where they may grow freely, but at the same time become strong and hardy before the time for planting outdoors, which under ordinary circumstances will be about the beginning of June, taking the place of some of the autumn-sown hardy kinds which will be now past their beauty. Those who have not the convenience for raising half-hardy annuals may usually purchase young plants for a small sum at the nearest nursery all ready for planting out; but it may be useful to remark that such popular kinds as Stocks, Asters, Marigolds, &c., if sown in very rich and light soil on a south border about the 1st of May, will produce sturdy plants that will produce as fine flowers, if a little later, as those raised in heat under glass, as all may prove who will try the plan fairly immediately after reading these notes.—H.

#### HELLEBORE AS A GRUB-DESTROYER, INCLUDING PHYLLOXERA.

THIS being the season when the destruction of grubs commences I wish more particularly to bring to notice the value of hellebore, and also to ask that gardeners would aid in experimenting with it. Hitherto I have never found the least injury done to plants by dipping them into a solution such as that mentioned on page 321, and it is certain death to all insects. For instance, "D., Deal," might dip his Auriculas; and, of much more weighty import, those with Vines affected by phylloxera might try this remedy. The French, I believe, offered a prize for the destruction of phylloxera; I suggest to them the above as a cheap remedy, and I firmly believe an effectual one. Fortunately I have had no phylloxera to experiment with, but in soil saturated with hellebore no insect can live, and yet plants are not injured.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street.*

#### A VISIT TO CHELSEA.

VARIOUS inducements exist to a visit to Chelsea. Chelsea buns, Chelsea china, and Chelsea Hospital have all their attractions. A melancholy interest will attach henceforth to a visit to the house of the Chelsea philosopher. My object was to visit "the Royal Exotic Nurseries." Having a friend high in office I was able to do so under very favourable circumstances, and advise all florists who have an opportunity to follow my example.

I was to some extent aware of the fame of Messrs. Veitch, but certainly not prepared to find a firm which pays away £10,000 in one year in wages. The statement of that sum alone will give an idea of the extent of their operations. Their agents appear to be in every part. Quite an interesting museum is springing up in one portion of the buildings containing the many objects of interest, besides the new and rare plants which are continually coming in to them. First impressions are imposing in finding oneself under glass in a grove of New Zealand Tree Ferns. Splendid specimens they are. "We do not care for them much under a hundred years old," said the "guide, philosopher, and friend" who was going round with me, Mr. Adolphus Kent, an old friend of now twenty years standing, and at one time the most successful of all Reigate Rose Association exhibitors. The glory of the place are, of course, its Orchid houses. There are 112 houses altogether, though I am thankful to say I did not enter half that number. It requires a tropical constitution for such tropical climates, though my companion rather enjoyed the atmosphere, and evidently pitied not a little my effeminate craving for fresh air occasionally. What the Orchids were is entirely out of my depth, but certainly the collection is equally extensive and magnificent.

The Pitcher-plants were also very interesting, and I was glad to find that the character of the insect-eating plants has been completely cleared. Mr. Kent holds that though a viscous fluid may detain flies in some instances, it is more than doubtful whether the plant partakes of them. "In fact we find," he said, "that if too many flies are caught by the leaves the plants get killed as well as the flies." On my way back—for I can detail but a very small part

of my experiences—I saw some beautiful Camellia houses, one especially capacious glass house being kept as the infirmary, to which the unfortunate plants which have been undergoing the rigours of a London season retire to recruit.

But whereabouts were the forced Roses? They were all away at South Kensington. Fortified with a pass from the obliging firm I followed them there, and had an early inspection of a very pleasing little exhibition. The Roses, principally from the firms of Veitch and of Lane, were not quite in full bloom, but looked very well and healthy. Beauty of Waltham, particularly good; also that excellent Rose of Mr. W. Paul, Magna Charta, which might have been called Magnum Bonum. That difficult Rose out of doors, Madame Lacharme, was excellent; a grand bush of Céline Forestier; Général Jacqueminot, as bright as ever; and Perfection de Montplaisir, a pale yellow, rather pleasing. A large collection of the various forms of Lent Lilies supplied a promise of the passing away of one more season of that "roaring month of Daffodils," which has this year invaded April and made so many remember him.—A. C.

I STROLLED in the other afternoon into Messrs. James Veitch's nursery at Chelsea; I was delighted with all I saw, and never remember to have seen so fine a collection of Orchids in bloom. I entered by the Old Brompton Road, and went through the glass houses in succession. In the entrance were some splendid Camellias, particularly one magnificent dark one of the colour of Louis Van Houtte Rose. The other house contained some splendid Azaleas and greenhouse Rhododendrons. Ericas also were very fine, and foliage plants in abundance. One house was full of that lovely plant so dear to brides and débutantes, the Gardenia. I was also fortunate enough to see the fine collection of Roses Mr. Veitch showed the day before at South Kensington. The finest bloom I saw was one of Marguerite St. Amand, but Countess of Oxford and other crimson Roses were very good. The rarely seen Mabel Morrison seems to do well as a pot Rose. This as seen at Chelsea is the purest white in colour of any Rose I know, it is in reality "paper white;" the plants were moderate sized, but very healthy and fairly bloomed. It is a great consolation to me, who have now no garden of my own, to know that during the next few months I shall be able to see the queen of flowers in her very best attire.

But after all I suppose at this season, and at a grand establishment like Messrs. Veitch's, the "Orchids" are after all not only the greatest attraction, but the flowers most prized. And really I was perfectly amazed not only at the number but also at the variety and the beauty of the flowers. I am not going to inflict upon your readers or upon your printer a string of long names, but I would recommend anyone who wishes to see what an Orchid really is to pay a visit to Chelsea during the next fortnight. Just as I was leaving I met the blest mortal who can call all that loveliness his own; he welcomed me, and expressed a hope that they might often see "WYLD SAVAGE," now no longer wild, and then hurried off, as he was starting that night for the bulb gardens of Holland.—WYLD SAVAGE.

#### THE NATIONAL AURICULA SOCIETY'S NORTHERN SHOW.

THIS Show was held in the Town Hall, Manchester, on the 26th inst. Generally the plants were poor, and seemed to have been pushed forward in order to have them in bloom. The pips were small, showing the effects of the long-continued cold weather. One of the best seedlings was a white-edged variety exhibited by Mr. T. Mellor of Ashton-under-Lyne, a seedling from Smiling Beauty crossed with John Simonite; the petals were rather pointed, but in other respects the flower was good. Alpines, with the exception of Mr. Pohlman's seedlings, were not first-rate. Polyanthuses were also far from being as good as in previous years. Mr. Barlow was as usual first with Fancy Auriculas, which were very fine. The twelve dissimilar Polyanthuses exhibited by Mr. H. Brownhill of Sale were also well grown. The following are the names of the chief exhibitors and the varieties best represented.

*Auriculas.*—Class A, six dissimilar varieties, Alpines excluded. First Mr. J. Booth, Failsworth, with Prince of Greens (the premier), George Lightbody, Alexander Meiklejohn, Lancashire Hero, Acme, and Charles J. Perry. Second Mr. B. Simonite, Rough Bank, Sheffield, with a seedling (green-edge) George Lightbody, Hero (grey), Mrs. Douglas, and Frank Simonite. Third Mr. Edward Pohlman, Halifax, with Alma, Catherina, Garibaldi, and Chas. J. Perry. Fourth Mr. Thomas Mellor, Ashton-under-Lyne; fifth S. Barlow, Esq.; sixth Wm. Bolton, Esq., Warrington; and seventh, Mr. Wm. Blackburn, Didsbury.

Class B, four dissimilar varieties, Alpines excluded.—First Mr. B. Simonite with Hero (green), a seedling; Mrs. Dodwell, Frank Simonite; second Mr. J. Booth with Acme, Marquis of Lorne, Alma,

Prince of Greens; third Mr. T. Mellor, Ashton-under-Lyne, with Ringleader, Reliance, a seedling green edge short of body, and a seedling self; fourth Mr. Edward Pohlman, fifth Mr. S. Barlow, and sixth Mr. William Bolton.

Class C, two dissimilar varieties.—First Mr. J. Booth with Acme and Dr. Horner; second Mr. E. Pohlman with a good seedling self and New Green (Headly); third Mr. W. Bolton with a seedling self and Alexander Meiklejohn; fourth Mr. S. Barlow; fifth Mr. J. Beswick, Middleton; sixth Mr. Thomas Mellor, and seventh Mr. B. Simonite.

Class D, pairs for maiden growers, dissimilar in class and variety.—First Mr. Edward Shepley, Middleton, with Rev. G. Jeans, Pizarro; second Mr. George Geggie, Waterloo Nursery, Bury, with General Niel and Mrs. Sturrock.

Alpines.—Class E, four dissimilar varieties.—First Mr. J. Beswick with Goliath of the Alps, Conspicua, Dolly Varden, and Diadem; second Mr. T. Mellor with Conspicua, Dazzle, Diadem, and Ovid; third Mr. S. Barlow with Brightness, Beatrice, Spangle, and Mercury; fourth Mr. E. Pohlman, fifth R. Gorton, Esq., sixth Mr. J. Booth, and seventh Mr. W. Brockbank.

Single Plants.—Class F, green edges.—First and third Mr. Booth with Colonel Taylor; second, fourth, and fifth Mr. B. Simonite with a seedling, Lovely Ann, and Talisman; sixth Mr. Mellor with No. 5 seedling; seventh and ninth Mr. Barlow with seedlings, and eighth Mr. Brockbank with Admiral Napier. Class G, grey edges.—First, second, third, fourth, and sixth Mr. Mellor with Ringleader, Confidence, General Bolivar, and John Waterston; fifth, seventh, and eighth Mr. Barlow with a seedling, C. E. Brown, and Complete; ninth Mr. Bolton with George Lightbody. Class H, white edges.—First, third, and sixth Mr. Mellor with seedlings and John Simonite; second and fifth Mr. Booth with Acme and Mrs. Headly; seventh Mr. Brockbank with Frank Simonite; eighth Mr. B. Simonite with R. Dean; and ninth Mr. Pohlman with Bright Venus. Class I, selfs.—First, fourth, and ninth Mr. Mellor with seedlings, second Mr. Pohlman with a seedling, third Mr. Shaw with C. J. Perry, fifth Mr. R. Gorton with Blackbird, sixth and eighth Mr. Booth with Ellen Lancaster and Marquis of Lorne. Class K, Alpines, single plants with yellow centres.—First, second, and fourth Mr. Pohlman with seedlings, third Mr. Beswick with Dazzle, fifth Mr. Shaw with Ovid, and sixth Mr. R. Gorton with Alexander Meiklejohn. Class L, Alpines, with white centres.—First Mr. Pohlman with a seedling, second Mr. Beswick with Conspicua, third Mr. Gorton with Beatrice, fourth Mr. Booth with a seedling, fifth and sixth Mr. Barlow with Little Annie and Elcho. The premier Auricula was Prince of Greens above noticed.

Polyanthuses.—Class M, black grounds, three dissimilar varieties.—First Mr. John Beswick with Congleton Queen, a seedling, and Lancashire Hero; second Mr. S. Barlow with President, Exile, and John Bright; third Mr. William Brockbank with Lancashire Hero, Exile, and Cheshire Favourite; fourth Mr. William Bolton, and fifth Mr. T. Mellor. Class N, red grounds, three dissimilar varieties.—First Mr. John Beswick with Lancer, George IV., and Unknown; second Mr. S. Barlow with Walsall Seedling, Firefly, and Sunrise; third Mr. Brockbank with Prince Regent, William IV., and George IV.; fourth Mr. William Bolton.

Class O, single plants, red grounds.—First, second, sixth, and seventh, Mr. Barlow, with Sunrise, Walsall Seedling, and Firefly; third Mr. Shipley with William IV.; fourth and eighth Mr. Beswick with George IV. and Unknown; fifth Mr. Geggie with Prince Regent. Class P, single plants, red grounds.—First Mr. Brownhill with Cheshire Favourite, second and third Mr. Beswick with Cheshire Favourite and Lancashire Hero; fourth, fifth, and sixth, Mr. Shipley with President, Exile, and F. D. Horner; seventh and eighth, Mr. Barlow with a seedling and John Bright.

Extra classes.—Class Q, for twelve dissimilar Fancy Auriculas.—First Mr. S. Barlow, second and third Mr. Wm. Bolton. Class R, for twelve dissimilar Fancy Polyanthuses.—First, second, and third Mr. H. Brownhill, Sale. Class S for twelve dissimilar Primroses.—First, second, and third Mr. Wm. Brockbank.

The miscellaneous collections of plants were particularly handsome, especially the Azaleas from Messrs. Jno. Standish & Co., whilst the blooms of Gardenias and Rose Niphetos were superb. Messrs. Robt. P. Kerr & Sons of Liverpool showed a fine collection of miscellaneous plants, and generally the stove and greenhouse plants were of good quality. Other exhibitors of miscellaneous groups were Mr. B. S. Williams, Upper Holloway, London; Messrs. Dickson, Brown, & Tait; and Mr. Brownhill of Sale.

#### EXHIBITING ROSES—WHAT IS AN AMATEUR?

A CORRESPONDENT on page 292 wishes the National Rose Society to define what an amateur is; but, as you say, there is no doubt that "an amateur is one who grows plants, but not for sale." I suppose your correspondent is alluding to the practice of some large amateur growers of Roses who dispose of their surplus stock by selling it. No doubt the practice is one to be discouraged, but I think the question is a very difficult one. For what are the great amateurs to do? Their ground after all is limited, and their plants are numbered by the thousand. Every year they are obliged, not only to buy new varieties, but to bud a large quantity

of stocks with old varieties. They find their ground quite full, when they every day expect their new lot to be delivered.

It is a question of getting rid of a few hundreds of old plants, and as the expenses of Rose-growing are very great they naturally wish to obtain a little money, so if they can find a purchaser they do; if not, they give them away. At the same time they are running a great risk in having their claim to the title of amateurs disputed. An instance of this is present to my mind as I write in a very flagrant case. But what was the end of it? A great nurseryman interfered very properly, and said the amateur was in reality a nurseryman, and could not show in the former's classes. The Committee endorsed this, and the result was that the amateur became a regular nurseryman, issued his catalogues, and is exactly like the rest of the trade.

But this was an exceptional case, and I do not think, so far as my experience goes, that at present the evil is great enough to cause the Committee of the National Rose Society any trouble. Perhaps your correspondent will go more into detail, when we shall be able to judge better of the matter.—WYLD SAVAGE.

#### SMALL FRUIT AND ITS PROFITS.

IN corroboration of Mr. Edward Luckhurst's article on fruit-growing for market (page 308), I venture to communicate the fact that 5d. per pound is what I have been in the habit for years of paying for Black Currants. Once only they were as low as 3d.; at all times they are scarce and little grown. Raspberries are 7d. a pint. Both these fruits we may say have semi-medicinal qualities, besides their value for kitchen and table. What can be more delicious as a temperance beverage than Raspberry vinegar, a tablespoonful in a half pint spring water? and as a preserve the Raspberry will retain all but its original aroma for two years.

But if "frost and cold winds" jeopardise the blooms of our fruit trees, much more do small birds ravage and destroy our bushes and canes; protection is almost impossible.—A. M. B.

#### REVIEW OF BOOK.

*Improved Pruning and Training of Fruit Trees, or Extension versus Restriction.* By JOHN SIMPSON. London: 37, Southampton Street, Covent Garden.

THE author of this small volume of 115 pages tells us that he "regards fruit culture from a purely utilitarian point of view," and he advocates what he calls the "extension" system of training. He abhors "fantastic methods of training, and the incessant prunings, pinchings, and root-prunings that these methods entail;" and he thinks, and most people will agree with him, that "a tree that can be grown in the shortest time and preserved in health and fertility the longest must surely be the best."

Years ago, before glass structures were so numerous and flowers in and out doors did not absorb the gardener's thought to anything like the extent they do now, more attention was given to fruit trees, and grand and fruitful specimens on walls were produced under a judicious system of pruning and training. We have as great an objection as the author has to stunted and distorted specimens; but we cannot ignore the value of pruning, nor do we like to contemplate the appearance of fruit trees grown in gardens if this "extension" system were solely and in many instances roughly (as must necessarily be the case), carried out. We readily admit that trees will form natural fruit spurs when the branches are not stopped, and we are aware that by injudicious pruning much fruit is sacrificed. With all this we have been familiar for years before Mr. Simpson appears to have made a special study of the matter; but we also know that "Nature's plan" if carried out in its integrity for a number of years will result in naked branches at the base, as all the orchard trees of matured age and all the forest trees that adorn the landscape show in the most conclusive manner.

More than thirty years ago we published the following brief instructions on the subject of pruning:—"After thinning out the shoots a little shortening of them must be attended to, at least whilst the tree is young and in the course of formation. Nevertheless, it must be remembered what is the object in view. Shortening contributes nothing to the health of the tree, nothing to its fruit-bearing properties. It is, in fact, an adjunct of a dwarfing system, being an attempt to limit the ultimate size of trees, in order to prevent them in gardens from attaining an orchard size and character;" and even when it was for a special purpose found necessary to "limit the size" of trees by shortening the branches a slight pruning of the roots was at the same time advocated. Again, in referring to the principles of pruning we have recorded that "thinning-out the growths is necessary, in order to admit or equalise the amount of light and air to the bearing wood,

and for the sake of increasing the size and quality of the fruit. Shortening, or pruning back the shoots, is practised for two principal reasons—the one to increase the number of shoots, and the other to cause the tree to produce abundance of side spurs. It must not, however, be inferred that any kind of pruning will of necessity render a tree more fruitful than if left in a state of nature. Pruning is altogether an artificial procedure, and becomes necessary principally through limitation of space. Nature has her own peculiar modes of pruning, if such they may be termed, and that is by suffocation, and by the continual tendency of the ascending or extending branches to weaken and finally to starve out the lower branches." This must inevitably be the result with such a tree as the one represented on page 23 of the book if the tree is left to Nature; indeed, the engraving from a photograph shows that the branches which formed the whole of the tree when it was planted three years ago, and which then had a number of buds, are now practically destitute of growths; and in proportion as the branches are allowed to extend without being shortened, in the same proportion will their nakedness increase towards the base, and in the course of time the centre of the tree would be destitute of foliage and of course of fruit, if the extremities were not checked, as they must be under glass, and "Nature's plan" (extension) then ceases.

A period of three years is quite inadequate for testing the system advocated, and it would have been well if the author had published a photograph of the tree that he planted (presumably under glass) in 1866. If that tree exists now it is yet comparatively young, and ought to be in its best condition. "Nature's plan," is very good when it is carried out in a natural manner; but fruit-tree culture under glass is fundamentally artificial, and the management must consequently be adapted and subordinated to the artificial conditions of the case. We admit readily that by no other means than those advocated by the author, and practised by many cultivators, could so much fruit have been obtained from a Peach tree in such a limited time; and we have not the slightest objection to those who prefer this plan carrying it out, and they will obtain abundance of Peaches in a few years; but the ultimate results of "Nature's plan" must be what we have stated.

There is much sound advice and excellent teaching in the book on thinning the shoots of fruit trees and other details of culture, and we have nothing to say against the good old system recommended as applied to orchard trees, nor, with certain modifications, to pyramids that have space to grow to a large size—indeed some of the finest pyramid Pears that we are acquainted with have for years received little or no pruning; but such trees do not meet the wants of all, and dwarf trees are and will be grown by many. That many of these are too dwarf and crippled—are, indeed, mere pomological toys—we admit, and that pruning is often most injudiciously performed is a fact we deplore; but this is not sufficient to induce us to relinquish a practice that when rightly carried out is undoubtedly beneficial. We do not believe that pinching the summer growths for the production of fruit is a delusion, and we do not hesitate saying that those who in their own practice have found it so have not carried out the system properly, or have applied it to trees that needed no such aid; but we do know that the finest fruit that has been produced in England has been obtained from trees that have been pinched and pruned in a skilful and systematic manner, and we also know that the most successful fruit-growers in France and America prune their trees intelligently and judiciously, and that pruning is advocated by those who grow fruit for commercial purposes.

There is much in the chapter on Vines that many gardeners will not accept and practise. For ourselves we do not think the system of Grape culture that has been pursued for many years by the leading cultivators is radically wrong, or the Grapes grown in British gardens would not be what they are—the best that are produced in Europe. If the plan advocated in the book under notice were adopted in every vinery in the kingdom, would better crops and finer Grapes be obtained than have been produced during the last twenty years? We ask the question, which is a pertinent one, and leave others to answer it.

We have dwelt at length on the subject of this small volume because it is a subject of great importance treated by a gardener of ability and experience. We believe the majority of readers will find much that they will approve in its pages, much from which they will dissent, and some things that they will not understand.

If a second edition is called for the author will doubtless correct the mistake he made in referring to a portrait of a tree in the *Florist*, but which was borrowed by that paper from the *Gardener's Magazine* and properly acknowledged. The information which has been supplied to the author on the lists of fruits is not quite satisfactory, while some of the names are

spelled incorrectly, as also, curiously enough, is the name in every instance in which it is mentioned of Mr. Coleman of Eastnor Castle. These are blemishes that might have been avoided by careful editorial revision. The illustrations are very inferior as works of art.

#### CAULIFLOWERS AND BROCCOLIS.

I BEG to add to the answer made to "G. O. S.," on page 268, that any Cauliflower might bear the name of Broccoli which would stand the winter without being injured by frost. Any Cauliflowers from seed sown in September, especially in England, may stand the bad season and thus become a Broccoli if the weather is mild, and especially if the head is not too strong when the first frosts occur. Likewise even the most hardy Broccolis are subject to freezing when the winter is severe. In France, and in regard to the time of sowing, Broccoli has no other signification than "Winter-Cauliflower." We readily class the Walcheren under the Cauliflowers, but to us Walcheren Cauliflower and Walcheren Broccoli are identical. It bears both those names, as it may as well be sown in March or in September, but then it stands the winter better than any Cauliflower.—H. MARTIN, *Paris*.

[The only certain mode of preserving plants of the Walcheren variety through the winter in England is by protecting them with glass. Plants raised from seed sown in spring produce heads in August; the variety is therefore known as a Cauliflower. Varieties of which Wilcove is the type cannot be made to do so; they are hence known as Broccoli, and are distinctly more hardy than Cauliflowers. On no practical grounds can Walcheren Cauliflower be placed in comparison as to hardiness with Wilcove Broccoli.—ED.]

AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Major Mason in the chair, the following candidates were duly elected Fellows—viz., James M. Alexander, G. W. Allen, Mrs. Edwin Arnold, Edward Banbury, Miss Blayden, Frederic J. Cornwell, Edward Fenner, Mrs. Hill, Sir Louis Jackson, Mrs. J. Leach, T. H. Stanton, Mrs. George N. Todd, William Wright.

— WE are requested to state that the Council of the ROYAL HORTICULTURAL SOCIETY, having procured a quantity of corms of Gladioli, are now distributing the same in packets to the Fellows on application at the Secretary's office, South Kensington; 3½d. in stamps should accompany each application if required to be sent by post.

— WE have had many references to the COLD WEATHER that has prevailed during the past week. A Sussex correspondent states that he found ice last Thursday morning half an inch thick, and similar accounts have reached us from other places. As yet, however, we trust that little or no injury has resulted to the fruit trees, as fortunately the blossom is late owing to the very low temperature that has generally prevailed during the present spring.

— MR. J. WITHERSPOON writes as follows upon EXHIBITORS' GRIEVANCES—"Mr. Ferguson's request being already attended to renders further attention to the same subject unnecessary, but the requirements of schedules and their being habitually disregarded I think needs again being brought forward. For Grapes the Edinburgh schedule stipulates that stands must not exceed 6 inches in height at the back, which is much too low to carry Grapes a distance, but I understand that the judges never notice this stipulation. Some day an exhibitor will enter a protest, and then perhaps the rule will be altered. Last year I wrote to inquire if any guarantee would be given against disqualification, but I was answered by the receipt of a schedule, and I stayed

at home. Have exhibitors not a right to ask that all such foolish restrictions be done away with?"

— A SPRING Exhibition was held by the ROYAL HORTICULTURAL SOCIETY OF IRELAND last Thursday, and it is stated to have proved very successful both in the number and quality of the exhibits and the attendance of visitors. Azalcas, though not numerous, were represented by some fine specimens, the chief prizetakers being the Rev. F. Tymons, with Messrs. Westby and G. Orr Wilson. Palms were well shown from the gardens of Lord Justice Deasy and Mr. G. Orr Wilson, the last-named exhibitor with Mr. Westby contributing a pretty display of stove and greenhouse plants. The Rev. F. Tymons and Mr. R. Pim staged the best examples of Roses in pots, and cut Rose blooms. Hyacinths formed a strong feature, some being very fine, especially those from Lord Justice Fitzgibbon and Messrs. Wilson and H. J. Jury. Many other plants, with a few dishes of Apples and Pears, served to constitute a very satisfactory Show.

— THE BULB BEDS AT DUNEEVAN were never more worthy of notice than they are now. Some twenty beds of Hyacinths, in which nearly six thousand bulbs were planted of the best bedding varieties in mixture, one-third being double, produce a charming and imposing effect. Each plant is supported with a galvanised wire stake, than which nothing can be more suitable, and hundreds of spikes are of exhibition quality. The beds are margined with Crocuses, the foliage of which forms an elegant green fringe to the masses of stately flowers which it encircles. The Hyacinths are about 8 inches apart, and one round bed contains a thousand plants, scarcely one having failed. The intermixture of double flowers imparts a more massive appearance to the beds than if single varieties alone had been planted. The Tulip beds are similarly fine. Mr. McIntosh has proved La Belle Alliance to be the richest and best scarlet bedder of all, and has superseded Vermilion Brilliant; the blooms are very large, colour intense, and foliage fine. Chrysolora has proved the best yellow for beds, the flowers being singularly clean and without spot or blemish. Molière, a fine purplish flower with orange base, makes a striking bed, the more so as the orange colour shines through the base of each flower like the reflection from an enclosed lamp; and Wouwerman, a glowing plum colour, forms a mass of great richness. The bulbs were planted 6 inches apart, and as there are practically no blanks the effect produced is as satisfactory as could be desired. The varieties named may well be kept in mind by those contemplating having fine beds of Tulips another year. Only newly imported bulbs of both Hyacinths and Tulips were employed, a few planted a second year being poor in comparison.

— MESSRS. JAMES CARTER & Co. have sent us a box of CINERARIA FLOWERS in twenty varieties grown in their nursery at Perry Hill. They are large and good in form and substance, the selfs being rich and varied in colour, and the particoloured blooms clear and well defined. Well-grown plants of such varieties as those before us would be valuable for decorative and exhibition purposes.

— THE American "Gardeners' Monthly" gives the following note on VITIS CALIFORNICA AS A STOCK AGAINST PHYLLOXERA:—Professor Eugene W. Hilyard says, "Among the resistant stocks most readily available to California Grape-growers, the native wild Grape, Vitis Californica, deserves earnest attention. In its botanical character it stands near the wild species, from which the Clinton and Taylor are derived; and while it does not seem to harbour naturally either variety of the Phylloxera, experiments made by planting it among infested Vines seem to show that, although some insects will migrate and attach themselves to its roots, it does not suffer in any sensible degree from this attack. It should be understood that under similar circumstances the

roots of the Clinton and Taylor are also visited by the insect, but without injuring vitality."

— THE *Reading Observer* states that on Wednesday, the 20th inst., the MARRIAGE OF MR. ARTHUR WARWICK SUTTON, third son of Mr. Martin Hope Sutton of Cintra Lodge, Reading, with Miss Arabella Constance Pym, second daughter of the late Rev. Edward Gambier Pym, M.A., Rector of Willian, Herts, and grand-daughter of Robert Baxter, Esq., of Westminster, took place at Christ Church, Westminster. After the ceremony, the wedding breakfast was served at Mr. Robert Baxter's residence, the guests assembled numbering about forty. Later in the day Mr. and Mrs. A. W. Sutton left for the continent, their destination being the Italian Lakes. There were over a hundred presents, including a very handsome silver tea and coffee service presented by the employes of the firm, a marble clock from the members of the Mildmay Club, a pair of vases from the Grovelands Club, a pair of etagères from the Abbey Hall Choir, a silver bowl from Lord and Lady Kinnaird, a pair of vases from Sir Henry and Lady Every, and a silver bracelet from Lady Anne Campbell, besides many costly and very beautiful presents from other relatives and dependants of the two families. In the evening the whole of those employed by the firm were entertained at the dinner in the Reading establishment.

— A CORRESPONDENT writes to us respecting A NEW VINE DISTRICT—"A Queensland paper, published in the western farming country, has the following account of a new agricultural neighbourhood opening up some three or four hundred miles from the seacoast, and long thought too distant for farms. The railway, however, now connects it with the port of Brisbane. The Roma fruit region is described. 'Mr. Bassett,' says the writer, 'is now reaping the fruit from his vineyard, which covers over twenty acres of ground, and contains 22,000 Vines, all bearing and looking as healthy as it is possible for them to look. The names by which the Grapes are generally known are—the black ones: Black Prince, Black Cluster, and Black Wine Grapes; white ones: Sweetwater, White Table Grape, and White Wine Grape. The Black Prince is a beautiful large Grape of an oblong shape, the largest grown in this district; it has a pleasant taste, and produces a very good wine. Of the white Grapes the White Wine Grape is the best. A stranger to the vineyard would probably take this Grape to be diseased, as it is slightly speckled with brown, which is, of course, its nature. It is a good yielding Grape, and produces a very good wine.' We are further told by the reporter that Mr. Bassett was putting in 15,000 more Vines at Roma Villa, and has a large press for the crushing season."

#### ROYAL HORTICULTURAL SOCIETY.

APRIL 26TH.

ROSES unquestionably constituted the most generally attractive feature of this meeting, though there were many other exhibits of excellent quality and interest. Altogether the meeting would bear very favourable comparison with any other held at this time of year.

FRUIT COMMITTEE.—Major Mason in the chair. There were only three exhibits, so the work of the Committee was very light. Mr. Lyon, gardener to Sir E. H. Scott, Bart., Sundridge Park, Bromley, sent a dish of Keens' Seedling Strawberry, very well ripened and of good colour. A cultural commendation was awarded, and also to each of the following—to Mr. Burnett, gardener to Mrs. Hope, Deepdene, Dorking, for several fine Paris Market Lettuces; and to Mr. J. Sutton, gardener to W. J. Cookson, Esq., Worksop Manor, Notts, for pods of Vanilla, finely ripened, and each 6 to 8 inches long.

FLORAL COMMITTEE.—Dr. Denny in the chair. The chief plant of interest among those staged in the Council-room was contributed by the Hon. and Rev. J. T. Boscawen of Lamorran, Probus, Cornwall, who sent a magnificent specimen of *Cattleya Skinneri*. Such has rarely been exhibited before. It was in a 10-inch pot, and had thirteen spikes, each with nine or ten flowers of the lovely soft purple tint peculiar to the species. The plant was in excellent health, the foliage firm and vigorous. A cultural commendation and a silver Flora medal were deservedly awarded to Mr. Boscawen for this handsome specimen. Messrs. James Veitch & Son, Chelsea,

exhibited several new plants, including two pretty Caladiums; one named Pyrrhus with large red and green leaves, and the other Princess Beatrice with yellowish green leaves and pink centre. Croton sinizianus had long narrow pendulous leaves regularly marked with green and yellow. Many other attractive plants were also shown and certificated. Mr. H. Cannell, Swanley, Kent, exhibited a collection of Laced Polyanthus from his own strain of seed, the flowers being generally of good form, and of dark ground colour with neat bright yellow lacing. A variety named Queen of Hose-in-Hose was shown with pretty hose-in-hose flowers. Plants of Chrysanthemum frutescens grandiflora were sent bearing a profusion of their large white flowers. Flowers of the deep scarlet Zonal Pelargonium Henry Jacoby, and a Tropæolum named T. canariense Improved, were also noteworthy. Messrs. Fisher, Son, & Sibray, Handsworth Nursery, Sheffield, exhibited a specimen of Rhododendron Lady Alice Fitzwilliam, with plants of R. magnificum, R. Princess Alice, R. Fragrantissimum, and R. Sesterianum for comparison. The first-named was in excellent condition, and was accorded a certificate. Mr. R. T. Veitch of Exeter sent a very handsome specimen of Rhododendron exoniensis about 4 feet across, and bearing a profusion of white fragrant flowers. Messrs. H. Lane & Son, Great Berkhamstead, sent plants of Deutzia gracilis variegata, distinguished by its small leaves being variegated with white. A vote of thanks was accorded to Messrs. J. Carter & Co., High Holborn, for a branch of Clanthus Dampieri bearing four extremely fine trusses of flowers. It was stated to have been cut from a plant with over one hundred trusses of blooms. The same firm sent a pan of a neat double red Daisy named Rob Roy, and a basket of the pretty variegated Forget-me-not, Myosotis elegantissima. Mr. R. Dean, Ranelagh Road, Ealing, exhibited a collection of Polyanthus and Auriculas, including several for which certificates were awarded. Specimens of the pretty herbaceous plant Epimedium rubrum were sent from the Society's garden at Chiswick, and Messrs. Heath & Son of Cheltenham sent a plant of a yellow Tree Carnation named Dr. Abercrombie, with flowers of good size and freely produced.

In the conservatory was a very handsome display, Roses predominating; the Rhododendrons and miscellaneous groups also contributing much to the general effect. Messrs. James Veitch & Sons exhibited extremely beautiful groups of standard Roses, with a margin of Acer polymorphum laciniatum, and flanked on each side by dwarf well-flowered specimens of Clematises, producing a charming effect. The Roses were in excellent condition, some in 10-inch pots bearing over two dozen flowers and buds. A gold medal was awarded. Messrs. Paul & Son, Cheshunt, obtained a similar award for a collection of about a dozen large specimen Roses, with a number of smaller ones, all in excellent condition. Among those particularly fine were Cheshunt Hybrid, Madame Victor Verdier, Beauty of Waltham, and Annie Laxton. In front of the stage were four baskets of Maréchal Niel Rose blooms, uncommonly large and of great substance. Messrs. Lane & Son, Great Berkhamstead, also secured a gold medal for two fine groups of Rhododendrons at one end of the conservatory, comprising over fifty large plants flowering very profusely, and representing numerous good varieties. From the same firm a group of Roses in pots was contributed, most of the specimens being fresh, healthy, and bearing good flowers.

Messrs. Osborn & Sons, Fulham, exhibited a pretty group of choice hardy and herbaceous plants, among which a basket of the variegated Heracleum Frederici was noticeable for its large deeply divided white-streaked leaves. Muscari Szovitzianum had neat spikes of dark blue flowers, and a pan of Trillium grandiflorum was also noteworthy, the pure white flowers being of great size. Messrs. Barr & Sugden had their handsome collection of Narcissi flowers. Mr. J. Aldous, Gloucester Road, staged a tasteful group of plants, chiefly comprising dark blue Cinerarias, Spiræas, white Azaleas, Lilies of the Valley, Chrysanthemum frutescens, Deutzias, Palms, Ferns, and variegated Maple, for which a silver Banksian medal was awarded, and a fine group of Cinerarias, Azaleas, and Wallflowers was contributed from the Society's garden.

First-class certificates were awarded to the following plants:—

*Davallia elegans polydactylon* (Veitch).—A distinct and handsome species, with bipinnate fronds about 2 feet long and a foot broad at the base; the pinnules are regularly cut at the margin, and bright deep glossy green; the apex of the frond being slightly crested.

*Asparagus tenuissimus* (Veitch).—A charmingly elegant species with extremely fine hair-like divisions of the leaves, similar to several other forms of Asparagus.

*Aralia Kerchoveana* (Veitch).—A very fine and distinct species, with palmate leaves, the largest of the divisions about 5 inches in length and the shortest 2 inches, lanceolate in form, deeply and coarsely serrated at the margin.

*Goniophlebium lachnopus* (Veitch).—Fronds 1 to 1½ foot in length, pinnate, and suggestive of a Nephrolepis; the pinnæ 1½ inch long, narrow, and with a slight glaucous tint.

*Rhododendron Lady Alice Fitzwilliam* (Fisher, Son, & Sibray).—One of the Princess Alice type, with dark green elliptical leaves 2 inches long and 1 broad; the flowers 4 inches across, white with a few pink streaks, very fragrant, and borne in terminal heads of three or four. A very beautiful variety, and apparently free in flowering.

*Kerria japonica major*.—A first-class certificate was awarded to J. McIntosh, Esq., Duneevan, Oatlands Park, Weybridge, for this plant,

of which flowering sprays were exhibited. The flowers were very full, bright yellow, and more than 2½ inches in diameter. The finest double form of this well-known plant that we have seen.

*Megasea cordifolia purpurea*.—Mr. R. Parker of Tooting obtained a first-class certificate for a fine specimen of this plant with large cymes of soft rosy purple flowers of good shape. The leaves are thick and rounded in form. It is well suited for culture in borders or pots.

*Erythronium giganteum*.—G. F. Wilson, Esq., Weybridge, sent flowers of this plant, which he stated in a note appended to be "distinct from E. grandiflorum, having only one flower to the stem, the flower being also of different shape, colour, and marking." The flowers were about 2½ inches in diameter, with narrow white petals and a central ring of yellow and red at the base.

*Cineraria Marched Past* (Cannell).—Flowers of great size and substance, exceeding 2 inches in diameter, rich crimson, with a narrow band of white near the centre. It appeared to be compact in habit, and is certainly a fine variety.

*Polyanthus Queen of Hose-in-Hose* (Cannell).—A second-class certificate was awarded for this variety as a border plant. It is very free in habit, and no doubt would prove very useful for the purpose named. The ground colour is deep red.

*Odontoglossum Alexandræ Regine* (Heims).—A beautiful variety with large flowers, the sepals and petals marked with large reddish-brown spots.

*Odontoglossum Ruckerianum* (Heims).—Also a fine Orchid, the white sepals and petals tinged with purple, and thickly dotted with small reddish spots.

*Auricula purpurea* (Dean).—A large double purple self of good form. This and the two following were certificated as decorative varieties.

*Auricula Splendour* (Dean).—A pretty deep crimson self with large flowers.

*Auricula Mrs. Moore* (Dean).—A laced Alpine variety with a pale yellow eye, deep purple body colour shading to a nearly white edge.

*Miles' Hybrid Spiral Mignonette* (Lyon).—Several pots of this excellent variety were shown by Mr. Lyon of Sundridge Park. The plants were extremely vigorous yet compact, with spikes of closely packed flowers 4 to 6 inches long. This variety has been frequently exhibited by the raiser in even better condition than on this occasion, notably in 1878; and it is curious that it was not certificated before.

SCIENTIFIC COMMITTEE.—*Potato Disease*.—Dr. Masters read extracts from a manuscript on this subject (the author's name being withheld). The chief point being that the writer imagines Bacterea or Englaena to give rise to the fungus Phytophthora infestans. He placed on a patch of cooked Potatoes some fluid containing Englaena, and after keeping it at a temperature of 60° to 70° Fahr. some fungus appeared in seven days, and after a fortnight the Phytophthora was developed.

*Sarracenia*.—Mr. W. G. Smith observed that the petals are usually pendulous; but on placing cut blossoms in a saturated atmosphere they became spreading and saucer-like. It was suggested that this was due to turgidity after having absorbed moisture.

*Rhododendrons*.—The Hon. Mr. Boscawen exhibited several trusses of seedlings, as also cut blossoms from R. Thompsoni and R. campylocarpum which had withstood 9° of frost. He also exhibited a branch of Andromeda formosa which was perfectly hardy, and which rabbits refused to eat, while it was poisonous to goats. He also exhibited a double wild Primrose.

*Scilla italica*.—Mr. Harpur Crewe exhibited a white variety of this flower from Mentone.

*Clanthus Dampieri*.—Messrs. James Carter & Co. forwarded a fine spray of this beautiful Australian Leguminous plant, for which a vote of thanks had been accorded by the Floral Committee.

*Violet Diseased by Puccinia Viola*.—Specimens were forwarded by Mr. C. M. Owen from Gorey, Ireland. The fungus was in a very incipient stage.

Books presented to the Lindley library: "Epitome of Gardening," by Moore and Masters; "Guide to the Literature of Botany," by B. D. Jackson.

LECTURE.—A *propos* of a group of Maples from Japan exhibited by Messrs. Veitch, the Rev. G. Henslow made some remarks upon the affinities of the existing Japanese and South United States floras with that of the ancient Miocene period in Europe. He observed that of the extinct Swiss tertiary flora and of the existing Japanese flora there are seventy-one natural orders or families in common. Fifty-one are represented by identical genera, but probably no species is now extant of that early period. The following orders and genera are characteristic of both the Swiss Miocene and modern Japan. Coniferae, Leguminosae, Lauraceae, Aceraceae, Rhamnaceae, Juglandaceae, Moraceae, Proteaceae, and Palmæ; Quercus, Salix, Ficus, Liquidambar, Myrica, and Ulmus. With the existing North American flora the old Swiss Miocene had even more in common than the Japanese. There are eighty-eight genera of seventy-three orders, which are represented both in Switzerland and the S.U.S. floras. The groups which especially characterise the U.S. forest vegetation are Taxodium, Magnolia, Liriodendron, Hickories, Walnuts, Planera, Maples, Negundo, and Oaks. About three hundred genera are common to the S. States and Japan, while the eastern side more nearly corresponds to the old world vegetation than the western side of N. America. A similar flora formerly extended throughout the Arctic

regions, as *Taxodium*, *Thuja*, *Chestnuts*, *Oaks*, *Walnuts*, a *Magnolia*, and a *Plum* had been found fossil in *Greenland*, *Maple* and *Tulip Tree* in *Iceland*, and forests of deciduous trees seem to have flourished where land is now perpetually icebound.

With regard to the origin of this similarity Dr. Unger considers the emigration to have taken place from America to Europe. He thinks the living flora of the eastern States of North America is the lineal descendant of that which gave rise by aid of "Atlantis," a supposed submerged land, which is thought to have connected Europe with America, to the Swiss Miocene flora. Sir C. Lyell thought the route taken was the longer one round by Japan and not by Atlantis; but still from America to Europe. Instead, however, of regarding either Switzerland or the South United States as the origin, there remains the theory of Professor A. Gray, that as the Miocene flora appears to have been uniformly spread over the whole of the regions bordering the Arctic circle, so, when the northern climates became cooler in the next or Pliocene age, this flora was driven southward along every meridian, its descendants now existing in the localities above mentioned. These now form a belt, roughly speaking, between the 30th and 40th parallels of latitude. Migration to some extent might have

taken place along that belt, but the greatest migration was probably from north to south.

The lecturer next called attention to the collection of *Clematis* exhibited by Messrs. Veitch, pointing out its connection with the Buttercups by means of *Anemone*. He alluded to the calyx being coloured and so superseding the necessity of a corolla, though this was present in the sub-genus *Atragene*. He described the European forms introduced in the sixteenth century and the splendid Japanese kinds imported within the last fifty years which have supplied the innumerable existing handsome sorts. The method of climbing by means of the petioles or leaf-stalks, which are sensitive to touch, formed the subject of some remarks. A fine specimen of *Cineraria* from Mr. Cannell's, which was named "Marched Past" was shown, as well as a branch from the old original *C. cruenta*, for comparison, which well showed what the florist's skill had accomplished.

#### DENDROBIUMS.

ORCHIDS are now represented in the gardens of this country by considerably over a thousand species and distinct varieties, of

Fig. 77.—DENDROBIUM CRASSINODE.

which probably nearly a fourth are included in the genera *Dendrobium*, *Odontoglossum*, and *Oncidium*. In the number of species cultivated these genera are nearly equal, and with the exception of about three species all have been introduced within the present century, thus affording some idea of the attention that has been paid to this most interesting and beautiful family of plants. Sweet's "Hortus Britannicus," published in 1826, enumerates but twelve species of *Oncidium*, only three of which were grown in the last decade of the eighteenth century; ten species of *Dendrobium* are named, all introductions of the present century; while the genus *Odontoglossum* is quite unrepresented as one of the earliest grown, *O. biconense* did not appear until ten years after the date of Sweet's work. Now there is not less than a hundred species of each genus in cultivation; and with the varieties, some of which are almost distinct enough to deserve higher rank, a total closely approaching four hundred is obtained—a remarkable increase in fifty years; but these numbers only refer to the forms grown in English gardens, and probably there are twice as many known to botanists.

Leaving for the present the *Oncids* and *Odontoglosses*, a brief review of the leading characters and most beautiful forms of the *Dendrobes* will enable some idea to be formed of the extent and diversity of this handsome genus as it is known at present. In few other groups of Orchids is so great a range of variation in habit noticeable as among the *Dendrobes*. Some have erect or pendent cylindrical jointed stems several feet in length; others have large club-shaped pseudobulbs, and a few have diminutive pseudobulbs an inch or two in height. In the modes the flowers are borne there is nearly the same diversity; some are produced singly in pairs or in triplets from the nodes of the stems, others are borne in dense racemes, and still others in long lax racemes. The flowers, too, vary greatly in size, and many beautiful shades of colour are represented; purples and yellows are particularly abundant, the rich golden tints in some of the species being unexcelled in the whole order. The species are epiphytal, and chiefly inhabit the East Indian continent or the numerous islands in that region, but very widely separated portions of the earth's surface also contribute representatives of the genus. For instance,

Australia, New Zealand, Brazil, Guinea, the Society Islands, Japan, and China possess typical forms of more or less beauty, but they constitute the minority, for the headquarters of the Dendrobies is that first mentioned, and thence we have obtained the majority of cultivated forms.

The cultural requirements of Orchids so widely dispersed must necessarily vary to some extent, but still this variation is not so great as might be imagined. Nearly all the species require a moderately high temperature and a very moist atmosphere in which to make their growth, with sufficient exposure to the sun to thoroughly mature it, and cooler quarters during the resting period. Pots, pans, baskets, and blocks are employed, some species succeeding under each system, while others require special treatment, which will be noted when describing them. As a rule the stronger-growing forms succeed best in pots or shallow pans, the baskets and blocks being appropriated chiefly to the service of the more delicate. The majority thrive satisfactorily in the East India house, but a few need a cooler temperature than is maintained in that structure. With but few exceptions Dendrobies are of easy culture, and give very satisfactory results if ordinary intelligent care is bestowed upon them, and there are several among them which rank high with the most useful Orchids in cultivation.

In so large a genus some system of classification is needed, and this Lindley supplied. He arranged all the Dendrobies then known in ten groups, distinguished by their habit and the modes in which the flowers are produced. The first three include only a few little-known species; but the fourth, which was named Eudendrobium, contains a large proportion of the most attractive forms. This is characterised by long stems, erect or pendulous, with the flowers in lateral pairs, threes, or sometimes singly—that is, produced from the nodes or joints of the stems. It is found convenient to further divide this group into two sections—one in which the labellum is undivided, and the other in which it is three-lobed, the former being much the larger section of the two. In noting the finest of the genus we will first take the Eudendrobium group, commencing with the species having undivided labellums.

*Dendrobium Pierardi*.—One of the oldest known forms of the genus; and though surpassed by many in richness and brilliancy of colouring, its flowers possess a delicacy of tints which still render the plant a favourite. Specimens were first sent to Dr. Roxburgh at the Calcutta Botanic Garden by M. Pierard, who collected them at Chittagong and in the Delta of the Ganges, where the plant is chiefly found. In 1825 the Hon. and Rev. W. Herbert included a plant in his collection which was said to have been received from Dr. Carey several years previously, accompanied by the following interesting note—"It is cultivated at Calcutta by tying it on a smooth branch of a tree, water being constantly conducted to it by a string through a small aperture in a vessel above, that so treated it hangs down the length of 6 feet covered with flowers after the leaves decay." The stems are generally pendulous, bearing the flowers from their nodes either singly or two or three together, each about  $1\frac{1}{2}$  or 2 inches in diameter, with narrow elliptical creamy-white or purple-tinted sepals and petals, the lip being pale lemon yellow, the base rolled closely round the column forming a kind of tube. The flowers are produced in the early spring months, and a succession of plants will maintain a display for some time. There are several varieties differing from the type in the size and colouring of the flowers, one of the best being *D. Pierardi latifolium*. Basket culture suits the species very well, the usual East Indian house affording the quarters best adapted to its requirements.

*D. cucullatum*.—Though not so beautiful as its close ally *D. Pierardi*, this deserves a word or two of description. By some it is considered a variety of the species named above, but it is principally distinguished by the lip being more ovate in form and more open at the base, the sides not being rolled round column to half the extent they are in *D. Pierardi*. The flowers are  $1\frac{1}{2}$  to 2 inches in diameter, suffused with a pale pink tint, the lip being pale yellow; in other respects it resembles its nearest relative very closely in habit, foliage, and manner of flowering.

*D. Bensoniæ*.—An extremely handsome Orchid from Moulmein, whence it was sent by Colonel Benson to Messrs. Veitch & Sons fourteen or fifteen years ago. The stems attain a length of several feet, are round and pendulous, with the nodes well marked, but not swollen as in the two following species. The leaves are 2 or 3 inches long, linear, and produced on the young non-flowering stems. The flowers are 2 inches or more in diameter, and are borne in pairs or triplets from the joints of the old stems. The sepals are oblong; the petals similar in shape but broader, and both are white, the lip being broad, rounded, and of bright golden colour, with purple blotches near the base. Though by no means common, this is now included in most of the best collections, and is deservedly admired by all growers. One of the finest specimens

I have seen was that in Mr. W. S. Leach's garden at Fallowfield a year or two since, and which under Mr. Swan's judicious care flowered most profusely in 1878. Like the preceding this Orchid succeeds well in a basket with a little peat and moss.

*D. nodatum*.—A pretty species very nearly resembling *D. crassinode* in habit, but with more slender stems, and the nodes are not so strongly marked, though more prominent than in most other forms. It is very pretty when in good condition, but unfortunately it flowers rather shyly, though free in growth and easily managed. Were it not for this defect it would deserve more general attention, but probably there is some little peculiarity of culture necessary which has not yet been observed. The flowers are produced singly from the nodes of the old stems, the sepals and petals being pale yellow, an orange-coloured lip tipped with white or yellow and blotched at the base with deep red. The column presents a curious contrast with these tints, the base being spotted with purple and green, and the apex (the anther case) bright blue. The plant was sent from Moulmein by Mr. Parish some years ago, and it may be satisfactorily grown under similar treatment to *D. crassinode*.

*D. crassinode*.—One of the most remarkable species in the genus, and also one of the most beautiful when in such condition as is represented in the woodcut (fig. 77), which faithfully portrays a plant recently growing in one of Messrs. Veitch & Sons' Orchid houses at Chelsea. It was in one of the pans which have been often referred to as so well suited to many epiphytal Orchids, and from the health of the plant and the freedom with which it was flowering when the drawing was taken it is evident that better results could not be obtained under any other treatment. It is astonishing how the plant with the roots in such a small space could support growths of so great a length and such numerous flowers. The species is a native of the Arrakan Mountains, where it has been observed at an elevation of 2500 feet. It was first found by Mr. Parish, but plants were sent to Messrs. Veitch and to Kew by Col. Benson about twenty years ago, and they flowered simultaneously at both establishments several years later. The manner of growth is so well indicated in the engraving that description is not required, and the single flower is also good, but the upper sepal is usually more obtuse than is there shown. In colour the sepals and petals are white tipped with rosy purple, and the lip has a bright yellow centre. There are several varieties, one of the best being *D. crassinode Barberianum*, which has much larger flowers than the ordinary form, the colour being much richer; indeed it has been not unreasonably considered to resemble *D. Wardianum*. Other lighter-coloured varieties are *album* and *albiflorum*, the former having been exhibited by Sir Trevor Lawrence in excellent condition, and certificated by the Royal Horticultural Society.—L. CASTLE.

(To be continued.)

## LECTURE ON THE AURICULA.

[Delivered by the Rev. F. D. HORNER at South Kensington on the 19th inst.]

HISTORY (Continued from page 308.)

THE earliest known varieties of Auriculas were Rule Arbitrator, a green edge, and Hortaine, a white edge; these can be traced back to 1757, Potts' Eclipse following ten years later. As years rolled on there were other Eclipses, notably Cockup's, and from this some better flowers were raised. All the green edges of that early period were of a pale colour and often bare in the dust or farina. Taylor's Victory was a highly prized green in 1776; but of all the principal varieties of that time only Jingling Johnny, a green of inordinately broad edge, Lord Lee, a lovely carmine flower but without meal, and Pillar of Beauty, a stiff and starched old white, are in existence now. Improvements were patiently carried on until in 1821 we begin to find some flowers that are good or familiar names at present. Col. Taylor and Booth's Freedom appear upon the scene, two green edges of which a grower with good specimens would not be ashamed to-day. In grey edges Kenyon's Ringleader appears, the ancestral flower of that grand family in the greys in which Laneashire Hero, George Lightbody, and Richard Headly are flowers of such high mark. At that time Taylor's Glory was a first-prize flower, along with Lee, Bright Venus, and others; and the best selfs were Whitaker's True Blue, still extant, Grime's Flora's Flag, and Redmayne's Metropolitan. I remember the last being sold for 24s. a plant, but half a century ago it grew in garden borders and might be had for 2d. a head. Ten years later—1831—the green edges were a stronger class by several flowers still to be found in old collections. Such were Pollitt's Highland Laddie and Standard of England, but nearly all the first prizes that year fell to Col. Taylor. To the greys were added Sykes'

Complete, a good flower grown at present, and Grimes' Privateer. White edges were augmented by Favourite and Incomparable from Taylor the raiser of Glory, and by flowers of less note. The selfs have additions, but the best is Othello, a round-petalled black flower that was much thought of.

Another ten years—1841—and the most notable green edge is Page's Champion, once very plentiful, especially with the raiser, who was wont to throw surplus offsets into the Thames, but now exceedingly scarce, and one of the very few Auriculas difficult to grow in an impure air. At this period came Conqueror of Europe among the greys with much sensation, and Ashworth's Regular, a small correct white edge, still valued by some old growers in the north.

By 1851 some of Lightbody's flowers appear, such as Star of Bethlehem; but that and all others were outshone by the first appearance in 1846 of Lancashire Hero, Robin Lancashire's magnificent grey. Like many other light-mealed greys it has the power of blooming in a green-edged form, and that generally occurs either on a truss from a young plant or one formed very early on an old one. The bloom of its middle life at midseason is rich silvery grey. This surpassing flower is worth a word by the way. When first shown, which was at Rochdale, 1846, it was placed second to a flower inferior to it in character—Grimes' Privateer. Lancashire had then eight or ten plants of his seedling, and in his grief hastily sold all for a trifling amount. He offered a good deal more to have them back, but could not get them. From their first purchaser they passed to Mr. James Cheetham, by whom it was eventually sent out. But it is truly Lancashire's Hero, and no name but that of Robin Lancashire should ever have been associated with this flower. It is the noblest type of an Auricula, and at its best there is no grey better. Our opinions are, however, divided, and some of us hold by Headly's George Lightbody as the model. This is a grand flower that was sent out in 1861, and the two greys will probably never pass out of cultivation while Auriculas are grown. They will meet immense competition and have worthy companions, but they are Auriculas right properly, and no florist wishes to see them discarded, but he will not rest till he has their equals.

By 1861 we also had Campbell's Pizarro, long our brightest roundest self of soft brown, together with more of Lightbody's flowers; and Campbell was busy for years at this time trying to give us a crimson self of standard properties. His work at that extended over many years, and is a good example of a florist's patience. He started with a cross between the old carmine flower Lord Lee and a puce-coloured self of Martin's. At once he got the colour but he lost the paste, Lord Lee having none; and when Mr. Lightbody communicated to me his neighbour's success in two crimson selfs, Duke of Argyll and Lord Lorne, there had been failures past all count.

2. I pass on now to speak of the Auricula from a florist's point of view, and I cannot better lay the subject before you in the abstract than in the words of a brother florist, the Rev. F. Tymons, before whom the Auriculas here have often stood for judgment. He says, "The points of a good flower are not arbitrary, as the uninitiated sometimes say, but really appealing to canons of beauty recognised and allowed by all who have made a study of the plant. Thus, as in any other matter of beauty or taste, the verdict of those most skilled in the subject is that which is entitled to weight. Rigid attendance to these points is of proportionate importance in any flower which is largely the creation of skill, stretching forward to some ideal standard. Capability of modification under culture so as to draw nearer and nearer to that standard is one of the prime distinctions of florists' flowers. Among these none probably are more artificial creations than the Auricula. Hence the importance of a thorough knowledge of what a good flower ought to be."

Auriculas are divided first into two distinct groups, separated from each other by the marked feature of mealed or unmealed centres. Those destitute of meal are termed Alpines, and their essential qualities are the unmealed centre and the heavily shaded petal. The highest form in the Alpine is the shaded petal and the golden centre, which last is not difficult to obtain except in such as have lilac or any shade containing blue. To admit shaded flowers of these tints it has been found necessary to allow a pale almost white centre, unmealed of course. This section is the hardest and most prolific of all Auriculas, and those grown in garden borders are Alpine blood of more or less inferior strain.

The other group is the Auricula Royal, containing all the edged classes, which constitute the highest and most wonderful development of this flower. The green edges hold the highest rank of all, and are the only class in which a mealy habit of foliage never occurs. The contrast of their zones of emerald black and white in a setting of silver leaves would be very beautiful; but Nature denies this combination, though often granting the converse in

white edges with green leaves. The green edges have required the most winning, for the edge must be absolutely pure from meal, and that has been found a very trying test. Now, however, this splendid property is becoming more brilliant and more fixed, but that it has been one of difficult attainment is shown by the very few true greens among the old varieties.

The grey edges, a strong class, are those in which a sprinkling of meal, like hoar frost upon springing grass, lies delicately over a green edge without hiding it further than to give a pearly effect as of a silver dew crystallised and secured upon it.

The white edges are exquisitely fair and lovely—a very favourite class. The whole face of the flower except the dark velvet rim of ground colour must lie deep under a snowy meal, usually of finer grain on the edge than middle of the flower. Good true whites have been very few indeed among the old flowers.

Then follows that beautiful consort of the edged classes—the self. This with its densely mealed white centre and colour of one velvety unshaded and decided hue is a very different flower from the Alpine, and not the least approach of the one to the properties of the other can be tolerated.

Such are the differences that form the class distinctions in the Auricula; we must look a little closer to see what those properties are that give expression and harmony to all. The perfection of a whole lies in the perfection of its parts.

I take a single flower part by part. In the centre, the tube with its contents—stamens and pistil—is a little member, but one of mighty import. No outer brilliancy compensates for a central failure here. The whole truth of the flower lies in this little well. It should be round and sharply cut and bright. A rich gold tube bathes the flower in a sunshine of its own, and lights up into life and radiance features that in themselves may be dull and commonplace; but the tube that is pale or green casts a moonlight effect around it that strikes all brightness dim and cold. Not only do we dislike, but we distrust a pale tube in the Auricula. A tube thus weak is never otherwise strong. Watery colours are associated with thin textures, and the flower so constituted cannot live out half its days.

Florists are called punctilious and severe—so we are; but it is with reason that we are particular to a point and exacting to a shade. The Primulas being dimorphous in the relative positions of their stamens and pistil, it has been thought a fanciful and narrow choice that we should adhere to that form only in which the anthers are set round the mouth of the golden tube and the pistil at the bottom, rejecting the longistyla or pin-eyed arrangement. With what comparison shall I illustrate the reason of our choice? I will take for an example the difference between the eye of sculpture and of life. You know the vacant stare of the one, the vivacity and soul that speak and sparkle in the other. The stony lifeless eye of an Auricula is a pin-eyed tube, with the set expressionless pistil, its one hard feature. But where the delicate gold-dusted anthers are set round the eye of the flower, and the obtuse stigma is all but sessile on its ovary below, we have the fulness, softness, and play of what is happily termed the "mossy eye." It is the counterpart in the flower of the living eye that is so much in the character of a face.

But I pass on to the next feature on the coloured disc, and that is the white circle we term the paste. This is a dry snowy meal, and it must be round and broad and bright and dense. Where these properties are wanting the flower has, according as the faultiness may be, a sleepy, unwashed, ill-tempered, mean, cramped, miserly look. Thus a lively paste and a golden tube, each sharply cut and circular, are supreme points in a highly bred Auricula.

Now we come to a zone or circle further outwards on the corolla. What contrast to snowy meal lovelier and more rare could a flower give us than a sudden change to the softest velvet? Such is the texture of the ring of colour known as the ground or body. Black has been the most usual, largely because black was the favourite colour with so many old growers. There have been strange local antipathies to anything but black, a prejudice which we hope to see overcome by the winning argument of equally true and beautiful edged flowers with blue and with crimson grounds. It is true that the best of the old flowers are those with black body colour, but the reason is that the Auricula, as if unwilling to cast her pearls before the unappreciative, has made few offers of gifts that were not sought and would not be valued at their worth. But in whatever colour this velvet zone exists it is imperative that it be pure—unspotted, that is to say, with any of the meal that may lie on the edge beyond it or the paste within. Colours also should remain true and fast, and not fade before the other parts of the flower into weaker shades.

The last remaining portion of the markings on an Auricula pip is that extraordinary circle of, green, grey, or white that bounds

the flower and determines by its nature the class to which a variety belongs. I will gather into one word the share which the flower in all its classes should apportion to all its zones, and that word is "BALANCE." Taking the pistil as the centre, then across the half flower in a radius line, the tube, the paste, the body, and the edge should be balanced by equal breadths. The tube should be bold and golden and thrum-eyed, the paste quite its proper breadth, and indeed rather over in the case of the selfs in which the body-colour really represents two zones; and therefore for a good balance the paste should represent rather more than one, or it will look narrow. The body flashes into the edge, but must not run out at the petal corners, and it must not be altogether flashes, but have a solid ring, and the more solid the better—without this the peneilling is thin and scratchy.

**CULTURE.**—As to the culture of the florist Auricula, it is not within the province of this lecture to give you a complete calendar of cultural operations. But it is amusing for a moment to peep into the potting sheds of the past old masters. It was a select school of cookery for the Auricula, in which the plants themselves were often victimised. The compost heaps were not so much an honest provision shop for the flower as its confectioners or druggists, where it was forced either to make itself ill with sickly sweets or was overdosed with dire stimulants till, after a flash of burning wasteful life, it died. One professor of long ago writing in dialogue conducts a horrified neophyte round his compost yard, where the young beginner is completely upset by an inspection of horrible effects from the slaughter house, sugar refinery, and other sources of refuse. "Our compost," says the master, over a vile compound, "is now in fine killing order; it would poison an Oak tree!" No! ent for your plants a few sods from a pasture which the Buttercups will tell you is sound and rich. Ramble in the woods, and instead of a cornucopia of wild flowers bring back what you can carry of mellow leaf soil. Ask the gardener for a little slice of the hotbeds that grew last year's Melons or Cucumbers. Make about equal parts of all you have with, say, charcoal to keep it open, and you have all the Auriculas will care to ask for.

As for the rest, keep their feet warm—*i.e.*, their roots well drained; their clothes dry in winter—*i.e.*, their leaves from wet. Remember that while the plant itself is hardy beyond limit, yet its refined blossoms are inexpressibly tender; that it belongs to the pretty family that loves a partial shade. Think how the bare trees and hedges let in all the winter sun upon the sleeping Primroses; how the young leaves on the boughs temper the sunshine over them in spring, and the full leafage hides them from it all the summer; and if you wish to grow seedlings which you should, be as much like Nature to them as you can. Sow them when she does—as soon as ripe; cover them as she does, which will be not at all, except by something that may represent the agencies of shade and moisture under which the young seeds grow, say a piece of glass over their cradle pot, and when they bloom they will be a great reward.

Here I draw to its close my story of a florist flower. I have wished to show you what a store of interest it has for the true florist. He may be a toiling man pent up in a dirty ugly town, but here is a flower that will smile to him in that capacity, and look a contentment that imparts itself, thriving as though the smoke drifts were but natural clouds, and the dry hard shadows fell from waving boughs. He has his few plants, and he will see more of Nature's features and variety in a frame of Auriculas than another who has no heart, and so no eyes, for such things, will notice in a whole landscape. In that innocent taste there is a pleasure very deep and lasting; and how much does the companionship of a friend like-minded add to it! The florist would rather have the steady continual sympathy of a brother florist the year round than beat a dozen strange competitors at a show. He must needs feel proud of his plants on their exhibition day, but that short excitement is only a small part of his whole pleasure and reward. Mere money profit is no motive in his attachment to his rural tastes and floral favourites.

At the exhibition tables a good loser and a modest winner, he is not the sordid mercenary man of whom there might be said, as it sparkles in the wit of Thomas Hood, that for him "the great god Pan is dead, and Pot reigns in his stead!"

It is remarkable how those who have loved this flower have loved it to the last. I could tell you of George Lightbody, who in a long illness would have a favourite Auricula at the bedside, and plants brought up that he might see what needed to be done; of Robert Trail, who past his eighty years, came to see the flowers

of his raising in our hands at the Northern Show; of Richard Headly keeping to a few Auriculas among the last of all his flowers; of old Robin Laneashire coming from his famed florist county to my own of the white Rose to see the Auriculas, and his eye, bright with an "unfamiliar brine," at the sight of Laneashire's Hero in his great glory.

It is no small thing to say of a favourite flower that it has been the first cause of many true companionships and fast friendships that will endure till all human interests here are at an end for us.

### A PLANT PIT.

CAN you aid me in erecting a plain, useful, and inexpensive pit for the growth of Cucumbers and Tomatoes in summer, and decorative plants such as Primulas, Cinerarias, bulbs, &c., in spring? I have heard of "sunken pits," but have no clear idea of what they are. Any assistance or instructions will be highly appreciated by "AN ARDENT AMATEUR WITH SMALL MEANS."

For the benefit of our correspondent and others whose "small means" deter them from erecting elaborate structures, we submit the following instructions from the April number of the *Gardener*.

"In the erection of pits, the conservation of heat by the means of 'mother earth' is very often under-estimated, if not ignored altogether. I think there is nothing that we can do with more advantage to our plants than endeavour to have them rather under ground than above it. The further a house or pit is raised above ground, the more it catches the bitter blast in winter. The roof we must have exposed; but why have the walls also exposed, when they

Fig. 78.

can be built for less money, and heated at less cost afterwards, by having nothing exposed to the elements but the glass roof? And not only is it of advantage in heating in winter, but it is of great advantage in the maintenance of more genial moist atmosphere in hot dry weather in summer, as everyone can testify who has had experience of such pits, or given the thing serious consideration. For a range of useful pits I would suggest something like what is represented in the accompanying section. Supposing *aa* to be the ground-line, mark off and level the soil where the outside walls are to be, and run it hard so that there is no chance of its sinking. On this build your outside walls, placing at intervals of 6 or 8 feet under the wall a right-angle elbow 3-inch sanitary pipe, socket end up, as shown at *bb*. By placing three bricks on edge round its end, and breaking off the end of the brick just above this pipe, a connection with the inside of the pit is secured. Another pipe, placed in the socket at *b*, will rise above the eaves of the pit; and to prevent wet entering, a tin or zinc cover can be supported 3 inches above the pipe by three pieces of stout wire, to fit inside the sockets. These will form ventilators which may in most cases be left open, except in severe weather; but when desirable to have them at command, a small shutter to each inside can easily be applied. When the mortar is sufficiently set, the spaces between the walls *dd* and also *ee* may be filled up with the soil excavated for a footpath *c*, building a wall on each side in the usual way. The space between the pits should be in the form of a gutter, asphalted, and made to carry the water to tanks inside the pits. These gutters should be 18 inches or 2 feet wide, and if the ventilators are placed alternately there will be plenty of room for cleaning out, attending to shading in summer, or applying mats or other coverings in the winter. A drain-pipe under the ashes in the beds will carry part of the water (otherwise wasted) back to the tanks. The inside arrangement of this pit is specially adapted to the growing of decorative plants of dwarf growth, such as Cyclamens,

Primulas, Cinerarias, Bouvardias, Achimenes, Begonias, Poinsettias, and dozens of other plants, which will do far better than in houses of any other description. But with a little modification of the arrangements it can be made equally suitable for propagating, forcing winter-flowering plants, growing pot Vines, Melons, Cucumbers, Tomatoes, &c.

"The great objection to these sunken pits is the necessity of having steps down to the doorways. This, however, is not always necessary. If they are built on sloping ground they may be so arranged as to be wholly under ground, except the ends in which the doors are placed. In such a case the end walls would have to be built first, the mean height of the soil ascertained and levelled in the same way as you would form a terrace, and upon this level, properly consolidated, commence to build as on level ground. In building a number of such pits a large tank should occupy the opposite end to the door, and these should not only be connected with each other, but should be made one tank, so that the water will run direct from the gutter into it. In every such tank a flow-and-return hot-water pipe should be placed, for the use of cold water in watering plants works untold mischief wherever it is applied in heated structures.—R. INGLIS."

#### A KENTISH WOOD IN APRIL.

WHATEVER may have been the effect of the past severe winter on our garden favourites, it has not diminished the glories of our woodland flowers. I have been here now for thirteen springs, but I do not think that I ever saw anything to equal their beauty this year. Our woods are somewhat peculiar; they are composed mainly of a few large trees, and amongst them a quantity of Chestnuts, Ash, &c., which are cut down about every eight or nine years close to the ground. From these a number of shoots spring up, which attain in the time I have mentioned the height of from 12 to 16 feet, and are then cut down and used as hop poles. The first year that they are cut down the flowers which fill the ground begin, under the influence of the greater light and air, to increase and show themselves; but the second year they come forth in all their beauty. We have one such wood close to the cottage, and I do not think I ever saw a more lovely sight than it is now. Imagine many acres of Primroses covering the ground in patches, and in places uprising above them great masses of the beautiful mauve-coloured Cuckoo Flower, *Cardamine pratensis*; while here and there are patches of the scentless Violet, and peeping up amongst them a plant of the early spotted Orchis. Now here is a combination that I suppose no gardener would ever attempt; and yet not only can I testify to its being a most pleasing one, but I can quite believe what Wallace, Burbidge, and other travellers in the tropics tell us—that, grand as are the plants and gorgeous their colouring and quaint their forms, yet nowhere is there to be found such a wealth of colour as we can show in the Primrose glades, the Bluebell woods, or the Gorse commons of bonnie England; and when we recollect the flaunting colours which so often distinguish our gardens, it is a relief to find that combinations so beautiful and yet so quiet are to be found in Nature's bedding-out.—D., Deal.

#### ROYAL BOTANIC SOCIETY.

##### SECOND SPRING SHOW.

THE second Exhibition of spring flowers for the year was held in the conservatory and corridor at the Society's Garden, Regent's Park, on Wednesday last, and proved very satisfactory both in regard to the number of exhibits and their general good quality. The following notes are necessarily brief, owing to the great demands upon our space and the brief time at our disposal after the completion of the awards.

*Stove and Greenhouse Plants.*—Several very satisfactory collections were staged in the classes for these plants. In the open class for twelve specimens Messrs. B. Peed & Son were first with small but neat examples of *Pimelea spectabilis*, *Azalea Gloire de Belgique*, and *William Bull*. Mr. G. Wheeler, gardener to Lady L. Goldsmid, Regent's Park, was a close second with healthy specimens, *Azalea Charmer* being particularly noticeable for the large size of the flowers. Mr. R. Butler, gardener to H. Gibbs, Esq., St. Dunstan, Regent's Park, was third with small plants.

*Azaleas.*—These formed an important feature in the Show, being generally well flowered. Messrs. B. Peed & Son, Streatham, were first with a collection of six neat profusely flowered specimens. Mr. C. Turner; Mr. Wiggins, gardener to H. Little, Esq., Hillingdon Place, Uxbridge; Mr. A. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham; and Mr. G. Wheeler secured the other chief prizes. The colours of the flowers were particularly bright, and some of the collections included really fine plants.

*Roses.*—In the classes for nine Roses in pots and six new Roses there were only two collections staged—namely, those from Messrs. Paul & Son, Cheshunt, for which the chief prize in each class was awarded. The plants were in excellent condition, the foliage healthy, and the flowers generally of good size and substance.

Rhododendrons and hardy Azaleas were exhibited by Messrs. Lane

and Son, Great Berkhamstead, who secured the principal prizes in both classes with some well-flowered plants of good varieties. Cinerarias, Amaryllises, and Pelargoniums were not largely represented, the chief collections being those staged by Mr. Wiggins, and for which were the first prize in each class. Mr. Douglas, gardener to F. Whithourn, Esq., Loxford Hall, Ilford, Essex, secured the principal prize for a collection of twelve Auriculas, all in vigorous health.

*Groups.*—These were extensive, bright, and tastefully arranged, the chief nurserymen's collections, as usual, forming the greater part of the display. The grand group of Roses and Clematises from Messrs. Veitch & Son of Chelsea occupied one end of the conservatory, and proved one of the chief attractions. A large silver medal was awarded. Similar honours were granted to Messrs. Paul & Son of Cheshunt for a very large collection of specimen Roses, the same as those referred to in our report of the Royal Horticultural Society's meeting; to Mr. Charles Turner of Slough for a fine group of small Azaleas, representing many handsome varieties; and to Mr. B. S. Williams for a collection of choice stove and greenhouse plants and Orchids. Silver medals were also awarded to Messrs. Cutbush & Sons, Highgate, for a very tasteful group of white Azaleas, Statice, Ferns, and Palms; and to the General Horticultural Company, Regent's Street and Anerley, for a large collection of new and rare plants. Large bronze medals were secured by Mr. Turner, Slough, for a group of Auriculas; Mr. Wheeler, for a group of miscellaneous flowering plants; Mr. Walker, Thame, Oxon, for four boxes of excellent Rose blooms; and Messrs. Barr & Sugden, for a collection of Daffodils. The certificates for new plants were not awarded when our reporter left the Exhibition.

#### HARDY FRUIT GARDEN.

CAREFUL attention should be given to Apricot and Peach trees in blossom, affording protection only when there is a probability of frost during the night, and on cold days when the sky is overcast. Opaque material should never be allowed to remain over the trees longer than is absolutely necessary to insure the safety of the blossom, embryo fruit, and tender foliage, such material having a weakening effect on the growth. A little trouble in removing the material in mild weather and replacing it when needed, would not only secure the crop but contribute to the health and durability of the trees. A small outlay in protecting materials would be a good investment, not only for choice kinds of Plums, Pears, and Cherries on walls, in addition to Apricots, Peaches, and Nectarines, but for plantations of bush fruits, bush, pyramid, cordon, and espalier Pear, Plum, and Apple trees.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—The dull cold weather lately has rendered careful attention necessary in ventilating and in the application of artificial heat. In the earliest house with the fruit advanced maintain a temperature of 60° to 65° by artificial means, with a slight increase by day so as to allow a change of atmosphere by moderate ventilation, allowing the temperature from sun heat to rise to 80°, 85°, or 90°, closing the house early. Tie-in and thin the shoots, stopping such as outgrow the limits assigned to them, and where the foliage is too much crowded near the fruit a few leaves may be shortened or removed. Fruit on the under side of the trellis should be carefully brought to the light by means of smooth thin laths placed across the trellis. If syringing be too long continued the fruit is liable to be disfigured and its quality deteriorated; therefore cease syringing and gradually lessen the supply of water to the inside border, but not to such an extent as to distress the foliage, or the fruit will not ripen freely, whilst the effect on the buds for next season's crop will be disastrous. When the fruit is nearly ripe some hexagon or other soft small-mesh netting stretched beneath the trees is useful to catch any fruit that may fall. Despite the unfavourable weather the condition of the crop under glass is generally satisfactory. In succession houses attend to disbudding the shoots and thinning the fruit.

*Figs.*—The earliest forced trees of the earliest varieties, such as Early Prolific and Early Violet, are ripening their fruit, when watering must be gradually reduced and syringing overhead discontinued.

Other varieties that have their fruit swelling may be supplied with liquid manure about twice a week and syringed at closing time. Keep the frame well ventilated in favourable weather, and this will improve the foliage and the quality of the fruit. When the Figs show indications of ripening generally reduce the moisture gradually both at the roots and about the house. At this stage keep the house freely ventilated, especially when the weather is favourable. The night temperature in all but the late houses should now range from 60° to 65° at night, and 75° to 80° or 85° from sun heat in the day-time. Proceed with tying-in the shoots required for extension or filling up vacant space, stopping the spurs at the fourth or fifth leaf and the laterals on these at the first or second leaf. Keep the borders suitably moist, and syringe twice a day to keep down red spider.

*Cherry House.*—When the roots of the trees are confined to the limits of the house the border should be well soaked with water, and if the trees are carrying a heavy crop and are not in a vigorous condition weak liquid manure will be beneficial to them. Syringe the trees twice a day, and keep the surface of the border constantly moist. As soon as the shoots have made four or five joints pinch out the points of those intended to form spurs, and carefully tie-in those required for the furnishing of the trees. These matters are important to secure symmetrical trees. Continue attention to former instructions as to temperature and ventilation.

#### MUSHROOM BEDS.

Collect materials for making beds in more open and airy situations than the Mushroom house, in which the Mushrooms after May invariably become maggoty. Rather less straw litter should be procured with the crude horse droppings, and after a sufficient quantity has been collected proceed to make up the beds, a shed open to the north being a suitable position. If materials are scarce, a mixture of about one-third leaves or sawdust will afford good results. Beds in bearing will need sprinkling daily with lukewarm water, damping around them occasionally. Supply beds that are too dry or showing signs of exhaustion with liquid manure at a temperature of 90° to 100°, and as a safeguard against insects follow in about a week with a good surface supply of water at the same temperature, with 2 ozs. of salt to each gallon.

#### PLANT HOUSES.

*Stove.*—Attention must be given at once to the propagation of winter-flowering plants. Cuttings of Begonias should be inserted, *B. insignis*, *B. Saundersiana*, *B. fuchsioides*, *B. nitida*, *B. Ingrami*, and *B. semperflorens* being useful kinds. When they are rooted shift them into larger pots, and grow on during the summer in plenty of light. *Plumbago coccinea superba* cuttings should be inserted with a heel, and *Luculia gratissima* now propagated and kept growing on freely during the summer will make useful flowering plants for conservatory decoration. *Sericographis Ghiesbreghtii* cuttings now inserted in loam with a little leaf soil and sand, and grown on, not allowing them to become root-bound until finally potted, stopping once or twice to insure bushy growth, will be useful plants in autumn. Insert cuttings of *Centropogon Lucyanus*, and when struck grow them in a light position, and not in too much heat. *Eranthemum pulchellum* and *Thyrsacanthus rutilans* should be struck from young growths, and *Hebeclinum ianthinum* also must now be propagated, young shoots striking freely. Cuttings of *Scutellaria Mocciniana* and *S. pulchella* now inserted around the sides of a 5-inch pot and afterwards shifted into a 7 or 8-inch pot, will make a fine display in autumn. Keep them near the glass to render the growth sturdy. *Aphelandra aurantiaca*, *A. Roezli*, and *A. nitens* are best obtained from seeds, but cuttings strike in moist heat. They should have a position near the glass in moderate heat, but plenty of moisture. *Centradenia rosea* and *C. floribunda* are pretty, blooming profusely. Cuttings struck now and grown through the summer make useful plants in 6 to 8-inch pots. Old plants of *Poinsettias* that have been kept dry should now receive water and be placed in a genial temperature, having cut them back previously. Those intended to furnish several heads of bloom should be cut back to about 6 inches from the base, and placed in a temperature of 60° at night in a light position to keep them sturdy. When they have started turn them out of the pots, reduce the balls at least half, and pot

in turfy loam. Plants to furnish cuttings must be near the glass, and when the shoots are about 4 inches long take them off with a heel, insert singly in sandy soil, and strike in heat, being careful not to keep them too moist. *Clerodendron fallax* and *C. fragrans* should be cut back, and when growing potted in sandy loam. The bright colour and grateful fragrance should secure for these a place in every stove. *Amaryllises* that are growing require weak liquid manure.

*Greenhouse.*—*Solanum Capsicastrum* cuttings inserted some time ago are now well rooted, and should be placed at once in 4-inch pots, and be kept growing in a genial atmosphere for a few weeks. Gradually harden them off, shift them into 6-inch pots, and plunge in ashes in a sheltered sunny situation; or in favourable localities they may be planted out and lifted in autumn. Old plants should be cut well in, and after they have started growing turn them out of the pots, removing two-thirds of the old ball, and plant them about 18 inches apart on a warm border until autumn, when they may be taken up and potted. *Hydrangeas* now being forced into flower have suckers springing from the base, and these inserted in small pots and placed in a little heat will root quickly, when they may be moved into 4-inch pots and afterwards shifting into 6 or 7-inch pots, and with good management they will flower finely next season. For conservatory decoration there are few finer plants than *Campanula pyramidalis*, both blue and white varieties. Turfy loam, with a fifth of well-decayed manure or leaf soil and a sixth of sand, will suit them well. Seeds sown now in a shallow pan in gentle heat will produce plants that will flower next year. *Humea elegans* if encouraged with liberal root room is useful for the conservatory. *Balsam*, *Cockscomb*, and *Globe Amaranthus* seed should now be sown, and the plants obtained will come into flower at a very acceptable time.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

##### KITCHEN GARDEN.

THE season is very late, and those who have sown and planted at the usual time have little to congratulate themselves upon. The summer will be here before we are prepared for it, and for this reason several important operations ought now to have been completed. The present is a good time to sow the main crop of Beet; as if sown earlier in many gardens it is liable to grow much too coarsely. A somewhat light soil, manured for the previous crop and deeply dug, is suitable. Sow the seed thinly in drills 15 inches apart. The same remarks are applicable to the main crop of Carrots. To maintain an unbroken supply sow Lettuce and Radishes in small quantities fortnightly in preference to larger sowings at wider intervals of time. Peas and Spinach should be again sown when those last sown are appearing through the surface. Suitable varieties of the former are Alpha, Hairs' Dwarf Mammoth, Nelson's Vanguard, and Laxton's Supreme, second earlies; and Dr. McLean, G. F. Wilson, and James' Prolific to succeed these. Of taller varieties Telegraph, Telephone, Champion of England or Huntingdonian, and Fortyfold. Suttons' Duchess of Edinburgh is also good for this sowing. Earth up those advancing, and place stakes to them before much growth is made.

When planting Cauliflowers, either autumn or spring sown, it is a good plan to distribute them in batches in order to lengthen the duration of the crop. Some of the strongest should be placed on a south or west border, others in an open warm position, and the remainder in the coolest part of the garden. Deeply dug and freshly manured land suits them, and they should be firmly planted with a trowel, or otherwise some of them will form heads prematurely. Large heads are not the best, and it will be found most profitable to dispose the plants rather thickly, says in rows 2 feet apart, and from 15 to 18 inches asunder in the rows.

If no Kidney Beans are sown it is advisable to raise a few plants in heat and transplant them to a warm border. A very profitable variety is Osborns' Forcing; 3-inch pots and any common soil may be used, with a little rough manure for drainage. Place two seeds in each pot, and the young plants should be hardened off and placed out quickly. Fifty plants will give several acceptable dishes. On a warm border sow seeds of Osborns' Forcing and Canadian Wonder or other main crop variety, the former in rows 18 inches apart and the

latter 2 feet. In warm localities the Scarlet Runners may also be sown. As before stated these may be profitably grown without stakes, the running growth being kept closely pinched in, placing the rows about 3 feet apart, and working in a row of early Potatoes between them. If stakes are employed the rows should be 6 feet apart, and between these two rows of early Potatoes may be grown, or if preferred early Cauliflowers may be substituted. The ground should either be trenched or deeply dug and well manured. The plants should on no account be crowded. Sow seed thinly in single drills about 2 inches in depth. Beans may be readily transplanted, and where chickens are troublesome it is advisable to sow thickly in any rough boxes and place the plants out before they have grown very much.

*Forming New Asparagus Beds.*—It is not yet too late to transplant Asparagus, the young plants, which only are suitable, being best moved when commencing growth. It is not absolutely necessary to trench the ground 3 feet or even 2 feet deep, as good results are obtained on ordinary deeply dug soil. Neither are beds necessary, and if the ground is moderately rich no manure need be dug-in the first season. Level a well-pulverised breadth of ground, shovel out wide drills about 3 inches deep and 2 feet apart, and in these dispose the plants 18 inches asunder. When planting spread out the roots carefully and cover firmly. Excellent Lettuces may be grown between the rows during the first two years. If beds are preferred they may be 5 feet wide, and planted with three rows, one in the centre, the others a foot from the edges. Where the fruit bushes are widely disposed a single line of Asparagus may very profitably be grown between them, and single plants wherever there is a wide opening. Surface dressing is preferable to digging manure in deeply.

#### FLOWER GARDEN.

*Sowing Seeds of Annuals.*—Bedding plants are very scarce, and for this reason annuals ought to be made to play an important part in the summer display. It is becoming late for sowing many kinds, but some seeds sown earlier have either not germinated or have been destroyed by insects. Mignonette is a general favourite, and will thrive anywhere provided it is not crowded. To economise the bedding plants sow Mignonette thinly throughout the largest beds or borders, and among the young plants place Pelargoniums, Stocks, Asters, and other bright-flowered kinds; or sow patches of Godetias, Candytuft, Hibiscuses, dwarf Tropæolums, Scabious, Stocks, Asters, Clarkias, Convolvulus minor, Lupins, Love-lies-bleeding, and others, according to their respective heights. Wherever annuals are grown it will be found a great mistake to crowd them, as the majority are branching in habit, and if this habit is encouraged the quality of the blooms will be superior, and the duration considerably lengthened. The seeds germinate most surely on light soils, and where the soil is heavy it is advisable to lightly cover the seeds with a little sifted sandy soil from the potting shed. Make the surface even, and water it if dry an hour previous to sowing. Sow Sweet Peas in small pots or where they are to flower. Seed of Carnations, Pansies, and Polyanthus for flowering next season may be sown in pans or boxes, and placed in a cold frame.

## THE BEE-KEEPER.

### HOW, WHEN, AND WHERE TO USE COMB FOUNDATION.

WHILE the advocates of the skep are still tenaciously clinging to the idea that their hive affords more comfortable quarters to its inmates than that with moveable frames—a position true at one time, but now most inaccurate if reference be made to the hive of to-day as we find it in good hands—we of the forward school may, for the present, be contented with the general admission that foundation, which we alone can use with comfort and the best effect, affords us an advantage which cannot be controverted. I need no further apology for endeavouring to give some hints as to the use and methods of manipulating this

modern invention, for we are now entering upon the time when these half-made combs in the body of the hive have their highest utility.

We have often been reminded of the severe logic of the cookery-book writer, who declared it to be necessary to catch the hare before proceeding to skin it, which seems to suggest that a few lines as to our selection of foundation from amongst the three or four varieties now in the market may not be out of place. I shall very briefly give the reasons for my preferences, which may have this recommendation, that I have no personal interest in the matter. All know that foundation consists of sheets of wax by some means impressed so as to determine the size and arrangement of the cells, while the sheet itself, as it is converted by the bees into comb, becomes the midrib of the latter, the general form and position of which can be so completely determined by the bee-keeper, that by the exercise of a little ingenuity the busy throng may be made to write their "Welcome," or draw some simple device in their inimitable tracery.

An examination of ordinary comb will show that the cells stand back to back, so that the centre of each cell on one side is over the point from which radiate the walls belonging to three contiguous cells of the other side, and that the edges of these walls are connected with the sides of the cell by three flat lozenge-shaped plates. The beauty of this plan as economising material and giving strength would require at least an article for its treatment, and it has been made the subject of more than one learned essay. Its value is self-evident, while a study of the ease makes clear a number of very curious co-relations. Ordinary foundation imitates faithfully this natural arrangement, and combs built from it have the disposition of parts found in hives innocent of "art and man's device." But the objection has been made that such foundation is disposed to stretch, and to prevent this a form has been introduced in which the cell walls are indicated upon a flat ground, but in the relation to one another, and to those upon the opposite side of the sheet, which we find in normal comb. This "flat-bottomed" foundation, if the stretching of the more accurate form had not been obviated, would have a *raison d'être*, and it must be admitted that as the bees work it out the thinning-down of the sheet produces the three lozenges, though in less marked form than in natural comb.

This make of flat-bottomed foundation must not be confounded, however, with another which marks the cell walls as the one just commented upon, but preserves no relation between the marking on the two sides of the sheet—a disadvantage from at least two sources, even if we leave the comparatively unimportant question of strength out of view. 1st, The cell ends are left unnaturally flat; and 2nd, In paring down the sheet the bees on opposite sides interfere with one another, as, if they persevered in forming the cell upon its true lines, the sheet would be pierced. They are thus prevented from utilising the wax, which in the ordinary and correct form supplies the material from which the cell walls are more or less completely elaborated.

In very hot weather foundation in full-sized sheets, whether flat-bottomed or otherwise, requires especial care if stretching is to be prevented; and this led to the introduction of wired foundation, into which thin iron wire is embedded during the manufacture. The promise was widely different from the realisation, for this foundation, though it did not stretch, the unremovable wires so worried the bees that in slack times they teased away their combs at the bottom in order to bare the wire, and so, if might be, eject it. I purchased between £3 and £4 worth of this novelty in order to test it thoroughly, and my condemnation is now endorsed by its own inventor. Any (dealers excluded) who would like to try it still may have a little of me in exchange for an equal weight of good wax. My own pronounced opinion, then, is in favour of the ordinary form giving the impression of the cell base, although upon theoretical grounds I believe this form should not be so distinctly angular as all existing rollers make it. This notice would not be complete without reference to foundation with a wooden midrib, which is no novelty, having been perfected several years since in America; and though it has great advantages for combs that are subjected to continued journeys, such as those in hives used for explanations with a bee tent, yet it is not likely to be extensively used, as the bees work it less freely than they do impressed sheets, and if at any place they bare the wood the comb is spoiled. Queen cells cannot be manipulated with it; its cost is somewhat greater than that of wax sheet, and near the edges the bees cannot be easily induced to work it at all. I had the opportunity of seeing several of these wooden-centred combs in Dorsetshire a few days since. Not more than half the cells had been built out, and the wood was in many places completely stripped of wax; the bees had in consequence been kept to the central part of the combs and had been terribly reduced, being

destroyed in detachments during the winter through being unable to decrease the number of their seams.

Having determined the make of our foundation, let it be understood that that which has been long in stock is not worked out so readily as that more recently manufactured, especially if it has been exposed to the light. This arises from the fact that a chemical change is brought about by this exposure, which raises the melting point 8° Fahr. besides decreasing the plasticity of the material at lower temperatures. The sheets by this process become whiter, it is true; but this is a disadvantage even for sections, as sheets of yellow wax, while they are softer, become perfectly white in the process of elaboration into comb.

Of course it is understood that foundations for sections, if used in size, must be of a special thin kind, and for the reason just given pale yellow wax should have the preference. I will refer to fixing the foundations in frames in a future issue.—F. R. CHESHIRE, *Avenue House, Acton, W.*

### SUCCESSFUL SHIPMENT OF HUMBLE BEES TO NEW ZEALAND.

THROUGH the kind aid of friends in Scotland I was able to send a package containing humble bees to New Zealand by the steamship *John Elder*, which left for Melbourne on the 9th December last, with instructions to re-ship from that port to Canterbury, New Zealand; and again on the 20th January I was supplied from the same source and shipped another parcel by the steamship *Norfolk*, which sailed direct. I have just received the *Timaru Herald*, which is so explanatory of the adventure that I thought it might interest your readers. Although the present result seems small it is encouraging to learn that the attempt has been so far successful. Considering that Mr. Frank Buckland and others have failed in getting these bees to the colony alive, it is a matter for congratulation that two fertile mothers have been let go on the wing at the Antipodes. Probably the fate of the last shipment has yet to reach England.—ALFRED NEIGHBOUR, 149, *Regent Street*.

[From the *Timaru Herald*, Monday, February 7th, 1881.]

"HUMBLE BEES.—The two queens, the survivors of a shipment of eighteen consigned to Mrs. Belfield, were turned out on Mr. Bristol's farm on Saturday morning. They were strong and healthy, and flew away briskly against the wind. Being liberated amidst Clover fields there is every chance of their doing well. Some years ago the present Premier of New Zealand attempted the introduction of this useful insect, but unsuccessfully, the last of the creatures dying within ten days' sail of our coast. Not being aware of any successful attempt at their acclimatisation being made heretofore, we believe that the pair of queens set free on Saturday have the honour to be the first of their kind in this country. The thanks of farmers are specially due to the lady, who, when in England about three years ago, saw Mr. Neighbour (a somewhat celebrated apiarian at home) on the subject of sending humble bees to New Zealand. Mr. Neighbour took up the matter, and promised when opportunity offered to send out a consignment, at the same time pointing out the risk attending such a shipment. That gentleman spared neither trouble nor expense in endeavouring to make the venture a success. In the first place, he employed an agent in a district in Scotland where the bees were unusually plentiful to mark down the nests in the summer, and then in the early part of the winter each nest with its queen was carefully dug out and placed separately in a nest of moss in a box for export. Being in a state of torpor when taken from the Scottish home it was a *sine qua non* that they should continue in that state the whole of the voyage to the Antipodes; consequently they were placed in the ice house of the *John Elder*, one of the Orient line of steamers. On arrival at Melbourne the box was handed over to the captain of the *Arawata* to carry on to New Zealand. From the appearance of fully one-half of the dead insects there is every reason to believe that they were alive on arrival at the Bluff but, unfortunately, a delay in their transit here took place, which was fatal to all but two. The telegram to Mrs. Belfield telling of their arrival was dated the 31st ult., at the same time intimating that the *Arawata* came in on the 26th. Yet further delay took place, and the interesting strangers did not arrive in Timaru till the 3rd inst. Mr. Hislop, late of the Timaru domain, kindly took charge of the box, and opened it out with the results as above stated. To our readers who are not farmers, and who may be ignorant of the value of humble bees, we may state that their great usefulness lies in impregnating red Clover, their long probosces enabling them to reach the pollen of the plant."

### TRADE CATALOGUES RECEIVED.

William Broad, Longton.—*Catalogue of Flower and Vegetable Seeds*.  
E. H. Krelage & Son, Haarlem.—*List of Hyacinths*.  
B. S. Williams, Victoria and Paradise Nursery, Upper Holloway.—*New and General Plant Catalogue for 1881 (Illustrated)*.

\*.\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Disbudding Vine (F. J.).**—The fruiting laterals should not be more than a foot apart on each side of the rod as shown in your sketch. Where there are two or more growths reduce them to one, but not until you can see the bunches, retaining those that appear to be the best. If two laterals show equally good bunches retain the one nearest the main rod. If your Vines do not bear well, or only produce very small bunches, it might be advisable to remove every alternate rod in the autumn and train up young canes from the horizontal branches. Vines outdoors usually bear much better from young canes than from old spurs. If your Black Hamburgh Vine is healthy you may crop it as you propose, provided the bunches do not average more than a pound each.

**Heat for Greenhouse (F. M. S.).**—It is impossible for us to name a date when you may discontinue fires, as this obviously must depend on the weather. We can only say that so long as a night temperature of between 45° and 50° can be maintained no fire heat is necessary for any of the plants you name; except, perhaps, during wet weather, when a little heat with ventilation may be advisable for dissipating damp, the fire in that case being lighted very early in the morning and continued for a few hours only.

**Auriculas (R. C. D.).**—Your only mode that we can suggest of "establishing a stock of fine Auriculas" is to purchase varieties from florists who grow these flowers for sale. It is against our rules to recommend dealers, but if you write to the trade florists who exhibited at the late Auricula show they will send you a list of the varieties they have for disposal. As to books, you will find our little manual on "Florists' Flowers" useful, post free 4d., and also "Hardy Florist Flowers," by Mr. Douglas, particulars of which can be had from the author at Loxford Cottage, Ilford, Essex.

**Inarching Vine (Reader).**—If you had let the Vines alone the union would no doubt have been effected—that is, if the inarching had been properly done. It is impossible for us to say whether you should take "another slice off in the same place," as we have no means of knowing the condition of the Vines at the parts on which you have operated. You must exercise your own intelligence on this matter; but we may inform you that you may inarch the young growths when they are a little firmer, and if the work is done cleanly and dexterously, the ligatures not being secured too tightly, the union of the two growths will soon be complete. The Alicante must be encouraged to grow above the union, the growth of the Lady Downe's being proportionally checked, but not violently or without due thought and consideration, such as a gardener would give to the nature of the work in which he is engaged.

**Deutzias not Flowering (Sol.).**—The spray you have sent indicates that your plants are in a very enfeebled state, and that either the root-action is defective or the soil exhausted. We should prune them rather severely—some of them, indeed, it might be advisable to cut down or nearly so, then place them in a genial temperature, syringe them frequently, and when fresh growth commences turn them out of the pots, remove a good portion of the old soil from the roots, and repot in turfy loam and a slight admixture of leaf soil and wood ashes. Your endeavour must be to induce the production of young growths from the base, and if these are matured and not shortened fine flowers will follow. Plants in a weak state are often much invigorated by planting them in good soil in the open garden, previously removing a portion of the old soil and potting them in the autumn. You can adopt which mode is the most convenient, as by either of them the plants may be considerably improved.

**Violas for Bedding (S. B.).**—We cannot undertake to name the "best blue and best yellow variety," because all do not succeed equally well in different soils and positions. What are considered the "best" in one garden and district may only be esteemed of moderate value in another. This we have proved by experience. We can inform you that the best blue Violas in Battersea Park last year were Blue Bell and Duchess of Teck, the latter a pale lavender blue; and the best yellows that came under our notice were Sovereign and Golden Gem. You may venture to plant these in quantity; and at the same time we advise you to try other varieties in smaller numbers, and you will then find which are the best for your purpose. You will find an excellent article on Violas, including cultural notes and a list of some of the best varieties, on page 321 of the Journal—the issue of October 7th, 1880. If you do not possess this number it can be had post free from the publisher in return for 3d. in stamps.

**Housetop Gardening (J. H. B.).**—Several years ago an attempt was made to grow Peach and other fruit trees in pots on some of the roofs in Cheap-side and in other districts of the metropolis; but owing to the inconvenience of conveying soil, manure, &c., to them the practice was abandoned. Fruit, including Strawberries in pots or boxes, might be grown in such positions, but not profitably, as better produce can be purchased much more cheaply. Plants and flowers could undoubtedly be grown in glass structures on the tops of houses as well or perhaps better than in cases attached to windows and on window-sills provided proper attention were given to ventilation and watering. In a nursery at Edinburgh a span-roof of glass has been formed on some buildings, and hundreds of plants are grown in excellent condition. We have seen good Grapes grown in a loft where glass had been substituted for tiles, the Vines being planted outside and trained up the wall, then taken inside; but this was not in London.

**Ionopsidium acaule (J. F., Nottingham).**—The "dwarf-growing plant with

a profusion of pinkish-white flowers, so charming at Regent's Park four years ago" was, we think, the above annual as exhibited by Messrs. Carter & Co. It has also been grown at Chiswick, and makes a pleasing marginal line to groups of plants. The seed should be sown very thinly, so that the seedlings do not become crowded in their young state, and about seven plants should be transferred to a 5-inch pot; or the seed may be sown in 5-inch pots and the superfluous plants be drawn out, leaving those remaining an inch apart. The plants should be raised in a cool and very light frame, keeping them close to the glass, and eventually removing the lights entirely, except in stormy weather and during drenching rains. Rich soil and abundant supplies of water are requisite for growing the plants healthily. When well cultivated the plants produce a charming effect, but if either starved or drawn they have a miserable appearance. This annual grows and flowers freely in moist soil in the open air.

**Annuals Distasteful to Slugs** (*G. Watson*).—We have nothing to add to the following reply we gave to a correspondent some time ago, and perhaps before you were a reader of the Journal—"There are few plants that snails and slugs will not devour. We have observed, however, that Nasturtiums (*Tropaeolums*), *Convolvulus minor*, *Limnanthes Douglasi*, and *Venus's Looking-glass* are not so much eaten as some other annuals; but our practice is to grow what plants are desired and destroy the slugs. When the annuals are aboveground sprinkle a little dry soot over them late in the evening or early morning; this makes the plants very distasteful to the snails and slugs."

**Black Currants Unsatisfactory** (*W. J. G.*).—The bushes are in a debilitated state—probably worn out, or nearly so, by neglect or old age, or both. If you were to prune a portion of them severely, almost cutting them down, and apply a heavy dressing of manure over the roots, the branches would in all likelihood push fresh growths altogether of a more vigorous character than the portions you have sent, and the bushes might again bear good crops. To cut them all down at once would be to deprive yourself of even a moderate crop of fruit for a year or two. You would do well also to plant some young trees. Such wood as you have sent is of no use for cuttings, and you had better therefore purchase young trees, unless, indeed, you can procure cuttings from healthy bushes in the autumn. We should not hesitate to cut some of the trees down at once, we mean by this shortening all the principal branches, and fresh growths would be produced during the present season. Copious supplies of liquid manure, as well as a rich surface dressing, would induce growths to break from the old wood. By adopting this practice we have converted tall useless old trees into dwarf free-bearing bushes, and obtained from them a serviceable supply of fruit.

**Whitewash for Shading** (*M. H. M.*).—You may take off the "white glare" by adding Brunswick green for the tint required. A very good wash may be made as follows. Ingredients: 1 lb. of wheat flour, half pound of whiting, and 1 lb. of common candle or Russian tallow. Make the flour into a paste and then put in the candles while the paste is hot, crush the whiting into a powder, mix with cold water, and then add to the paste, also adding as much Brunswick green as you need. When required for use warm it in a pail and paint the glass when the sun is shining upon it. The *Rhododendron* is, we think, Countess of Haddington, but the blooms were far too withered for satisfactory identification.

**Crimson Vesuvius Pelargonium** (*Hender & Sons*).—The flowers unfortunately arrived in a very withered state, but we had no difficulty in perceiving that the colour of your "sport" is decidedly deeper and richer than the parent; the flower stem is also stouter, and truss and flowers larger than those of *Vesuvius* that you sent for comparison. This is the darkest of all the forms of the singularly sportive variety that has come under our notice, and will doubtless be valuable both for pots and beds.

**Eucharis amazonica** (*R. C. S. P.*).—As we had a suspicion that the insects to which you referred as "eating into the roots" were not the cause of the unhealthy condition of the plants, but rather the result of decaying matter at the base of the bulbs, it became necessary for us to keep the examples you sent for some time for examination and experiment. We are now able to say that the insects are not the primary cause of your plants not blooming. By drying the bulbs we have cleansed the base of the decaying matter, and find that the insects have not penetrated the healthy parts. The roots of the plants are in a very bad state—either the result of unsuitable soil, injudicious watering, or they have been seriously checked by the plants having been removed from a warm house into one too cold for them. Let the cause, however, of the decaying roots be what it may, there is only one course for you to pursue in reinvigorating the plants. Turn them out of the pots, removing the soil and every particle of decaying matter from the bulbs, washing them if necessary in warm water. When they are dry pot them in small pots filled one-third with potsherds, the drainage being protected with moss or fibre from which the soil has been shaken. The compost employed should consist of turfy loam and a little peat, but the latter is not essential, and a liberal admixture (at the least one-sixth) of bruised charcoal, a little of which crushed to powder should be placed round the base of the bulbs. The pots should be placed in a stove, and if they can be plunged in bottom heat it will be a great advantage. By adopting the practice indicated and exercising great care in watering you will promote the emission of healthy roots, and this being accomplished the plants will in time regain their lost health. You would do well, perhaps, to obtain some healthy plants from a vigorous stock, as once established in a healthy condition the plants are easy to manage; but it is not easy to "bring round" plants that are in such an unsatisfactory state as yours appear to be. If the soil is moist when used, and the pots are plunged, no water will be needed for a week beyond an occasional sprinkling with a syringe, as if the soil is kept wet fresh roots will not readily take possession of it. We think that your plants, considering their comparatively rootless state, have been much over-watered.

**Names of Plants** (*Young Gardener*).—1, *Caltha palustris*, Marsh Marigold; 2, *Alliaria officinalis*, Jack by the Hedge. (*W. E. B.*).—1, *Festuca ovina glauca*; 2, *Coccoloba platyclada*; 3, is a *Billbergia* or *Pitcairnia*, but was too withered to be determined; 4, *Maxillaria Harrisonae*; 5, *Anthurium Schertzerianum*. (*W. C. N., Devon*).—1, *Cereus McDonaldiae*; 3, *Salvia Grahami*; 4, *Kaulfussia amelloides*; 5, *Eupatorium rupestre*; 6, The Fern is not sufficient for identification; it resembles *Asplenium obtusatum*. We do not undertake to name Roses, nor varieties of any other florists' flowers, still we do not object giving the names of those we can readily identify. The bloom sent is too much expanded, and we can only say it resembles *Madame de St. Joseph*. (*W. H. R.*).—1, *Narcissus moschatos*; 2, *Narcissus nobilis*.

**Bees** (*Inquirer*).—"The Apiary" by Alfred Neighbour is a good modern work on bee-keeping. Special attention is devoted to bees in our columns, to which the leading apiarists of every "school" contribute.

**Boiling Bees' Combs** (*W. K.*).—The quantity of water is not material. If you boil the combs thoroughly until dissolved the wax will rise to the surface, and can be collected when the water has cooled.

## COVENT GARDEN MARKET.—APRIL 27.

We have been well supplied with house fruits this week, and prices have been somewhat lower, more particularly with Grapes, some very good samples reaching us from the Channel Islands. Trade improving.

## POULTRY AND PIGEON CHRONICLE.

## AGRICULTURAL IMPLEMENTS AND MACHINERY.

IN again referring to this interesting and important subject we will first notice a novelty—namely, a patent manure spreader, shown at Islington Hall last December by Messrs. Pamphilon and Co. This machine is intended for attachment to the rear of any loaded manure cart by patent connecting apparatus. The interior consists of an endless sparred traveller band, the cross-bars having short spikes so arranged as not to follow in each other's track. Over the traveller band an arrangement of bent knives revolves in the opposite direction, so as to cut up the manure as the spiked band brings it forward, distributing it on the land of uniform thickness. Above these is an oscillating cleaning fork, with a number of prongs pendant from a rocking shaft, for the purpose of preventing the knives from clogging. In front the mouth of the machine is so formed that, with a dung grapple by the man unloading, the manure can be drawn on to the endless spiked traveller band. Motion for driving the endless band and the revolving shaft is taken from the supporting wheels. The thickness of the feed can be regulated partly by the man with the dung grapple, but chiefly by the speed of the traveller. The machine has been in use for some time, and those who are using it speak highly of its merits.

This machine effects a great saving of labour, and also economy in the application of the manure, for the manure can be distributed very quickly, and with greater regularity than it is frequently done by hand labour. Another point is, that as fast as the manure is laid out it can immediately be ploughed down—a matter of importance at certain times of the year, because whilst the dung is fresh it is more easily covered and buried by the act of ploughing-in. Long dung can also be severed and more easily distributed by the action of the machine than is done by hand labour. Nor has the dung time to lie about in heap, losing moisture as well as ammonia, if the land is ploughed close behind the spreading machine. The use of the spreader in pasture land is that the action of the manure will be immediate; and the regular

distribution of the dung, even if in a long undecayed state, is of consequence, as less labour will be required for the chain harrows and roller.

Ploughs now require attention, though steam culture should generally be adopted for the fallow ploughing, and also for the heaviest and first work done on the fallows in the spring; as this not only makes all the work afterwards much lighter and easier for animal power, but lighter implements are only required to complete the spring and summer labour on the fallows intended for Potatoes and roots. Thirty years ago we availed ourselves of the light one-horse ploughs made by Howard's firm, and by its use great saving was effected in the light spring working of the land, not only in preparing and completing the tillage for Lent corn, but also for Potatoes and other root crops. About this time many persons commenced farming upon the market garden system on a small scale, in various instances tilling not more than 5 or 6 acres, and keeping only one strong active horse. These small ploughs of easy draught exactly suited the work, especially as some of the land was of a sandy and gravelly nature. These one-horse ploughs are still remarkably useful in planting Potatoes and general cultivation upon small farms.

Upon farms of 100 or 200 acres we have since had the advantage of the use of the double-furrow ploughs. All the chief implement makers sell them. The draught is quite within the power of two horses, which for farm economy should never be under 16 or 16½ hands high, with strength and substance in proportion, and in the double-furrow plough no driver will be required. The lifting-out is done in turning or at the land's end entirely by the horses. The ploughman has merely to release a lever handle, when by the onward progress of the horses the shares are lifted out of the ground, which greatly facilitates the turning. By the patent steerage we have this great advantage, that by one simple lever both the land and furrow wheels are locked or steered; the plough is therefore easily guided, even on the steepest hillsides. Practically these advantages are nearly all that we require in the absence of steam power, for when we have horses of such power as indicated each one will turn his furrow in ploughing work, and in carting work, &c., will be equal to a draught of 25 cwt. or upwards, and unless horses of this size and power are employed we cannot reap the full advantages to be derived from the use of improved tillage implements. It must not be forgotten that these double-furrow ploughs called new and convertible are capable of being changed in a few minutes into an equally efficient single plough with or without wheels. By this arrangement when the second plough is removed there are no loose parts likely to be lost. The beams are of steel tapered from end to end both in width and thickness, thereby giving lightness and rigidity. The depth of ploughing also can be altered without stopping by the ploughman using the lever. This plough is capable of another change in work, for by the removal of one plough a subsoiler may be fixed in front and preceding the plough body; the treading the furrow by the horses after subsoiling is therefore avoided, as the pan of the last furrow is broken up just before the new furrow is turned over it.

Triple-furrow ploughs are also made, for since the introduction of steam ploughs it has led the farmers, especially on light land, to desire that their ploughs should take a greater width, and the triple ploughs have been brought out to meet this requirement. In the draught of this plough three horses of the requisite strength are only required, and thus, as in the case of the other ploughs, each horse turns a furrow. By its use greater economy as well as expedition in ploughing is effected than with the double-furrow plough, into which it may at once be converted by the removal of the hinder body, and the depth of the work can be regulated by the lever as the plough proceeds, and at the ends the

plough is lifted by the same lever clear off the ground. Combined subsoil and pulverising ploughs are now much in demand; they are fitted with digging breasts and subsoil tines, which break or pulverise the soil to a depth of 6 or 9 inches below the furrow. The horse power required for this work cannot easily be defined on account of the variation of the subsoil to be operated upon. Market gardeners and farmers, however, find these ploughs very efficient implements for deep tillage; and as they are easily turned into an ordinary plough by changing the breast and removing the tines they are much approved, for practically it is quite out of the range of economy to be provided with a separate implement for the various requirements of a well-managed farm of the present day, especially when we find that market garden farming is becoming the practice in those districts where a ready sale and delivery can be obtained for the various crops to suit the requirements of the consumers of vegetable produce in the metropolis or in large provincial towns.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—All those who have employed steam power in the early cultivating of the fallows are now getting forward with the tillage; and the Potato planting having been finished, the Mangold seed should be drilled without further delay. The safest plan is to sow the Mangold seed as soon as possible after the first week in April, and all we have to fear is that in case the weather should continue dry the seed may not germinate; at least, that was the case last year, and a large portion of the plant was deficient in consequence. Sometimes we have seen a crop of mixed Mangolds and Swedes answer well, especially where fattening cattle are fed in the boxes in the autumn; the Swedes being very early become ripe and fit for use at an early period. They are also useful for a milk-selling dairy, the Swedes being a good supplement in case the autumn grass becomes scarce. The early-sown Barley and Oats, as well as Peas, are now looking very strong; the late mild weather and timely showers caused all seeds to germinate with great regularity this year. We do not advise sowing Barley after the 20th of April, but prefer to sow white Waterloo Oats and Barley mixed. The Rye crop is forward this year, and is now being cut up for cattle or being fed off on the land with sheep. In either case this land where clean may be sown with Mangold, Swedes, or hybrid Turnips for early feeding. In case, however, dry weather should prevail it is better to plough and drill the seed the same day, because when the ploughing, working, and drilling are done simultaneously the seed is sure to vegetate, especially if the surface is rolled with the ring roller. Summer Vetches for successional use for feeding cattle or sheep may now be sown with advantage, particularly upon strong soils intended for Wheat, as we find the ground comes in good condition after being cropped with Vetches and fed off by sheep eating cotton cake; also, in case the land is outlying, as no dung carting will be required, because a dressing of Peruvian guano at seed time after the green crops have been fed off will insure a good crop of Wheat in ordinary seasons. Upon this plan also the last ploughing and seeding may be done in good time. Farmyard or box dung should be used nearer the homestead in order to save carting—a matter of much importance not only to the labour bill but in the saving of time in laying out, &c.; in fact, as a rule the outlying fields may be dressed by sheep with great advantage, either in the case of feeding-off green crops or early roots.

*Hand Labour.*—This will still be required in connection with tillage operations, such as couching, carting, and heaping or burning on the land. As the first week in May is the best seed time for the cattle Carrots the seed should now be prepared by hand-rubbing with the harvest gloves, if it has not been already done, as this work can often be done on a wet day when the men or women cannot work out of doors. It is, however, an important method of preparing the seed, because where the burr has been rubbed off properly the seed will then pass with great regularity through the drill, quite as much so as Turnip or Mangold seed. Carrots of the White Belgian variety may be said to be best for a full crop for cattle-feeding; but the Red Intermediate are of rather higher feeding value, and they may sometimes be sold in the market when vegetables are scarce, like they have been during the past few months. There is, however, the labour question to be considered, for these Red Intermediate sorts are short and clean grown when the land has been properly tilled and manured; and although they will come large in size, yet they do not root deeply in the soil, and are easily taken up; therefore the cost of raising the crop is reduced to a minimum.

*Live Stock.*—The dairy cows are now out grazing at daytime, but our plan is not to let them lie out at night until the second week in May, for we often have night frosts up to that time, and sometimes later; and when the animals lie out at first they should have the driest and highest pasture on the farm—at all events it should be situated above the fog level, for it is the moisture floating in the air which does the mischief when accompanied with frost. These remarks apply to other cattle as well as to dairy cows, for it is found that

well-bred and well-fed young cattle are very apt to suffer from the quarter ill, unless great care is taken with them on their first leaving the cattle courts and yards in the spring. The fat tegs or hoggets are now being shorn before being sent to market, especially in the event of their being ripe fat, but those in only moderate condition will sell best in their wool for another few weeks. Great care will also be required in washing them in readiness for shearing, for when washed in a pond or stream it requires great care so that no animal may remain in the water beyond his turn, as we have known sheep lost when taking in a quantity of water internally, and particularly when the animals are very fat, because they are then in a helpless state. We prefer tank-washing where the tanks are conveniently constructed for the purpose. The weaning of calves will now be going on, and in case they are to be steered and fattened at two years old they cannot be too well kept from the first, and should receive after weaning not only the best advertised substitutes for milk, but also cake and beanmeal; and until they are several months old they should either be kept in yards and sheds, or otherwise in a dry sheltered paddock with night quarters adjoining, eating dry fodder, such as *Trifolium* and Vetches, until the earliest roots or Kale are ready.

#### VARIETIES.

**NIGHTINGALES NEAR LONDON.**—Will any of your readers kindly tell me where I can hear the nightingale within a few miles of London? All the time I have lived in Dorset I have never once heard a nightingale, and I believe no one else has either. But when I was living in Sussex I used to hear them sing both by day and night. I am particularly fond of listening to these lovely vocalists, and if anyone will tell me a good place near to London where I can once more hear them I shall be very much obliged to them.—WYLD SAVAGE.

— **THE BANTAM CLUB.**—The long-talked-of Bantam Club is, we understand, really in process of constitution. A meeting for the appointment of officers and consideration of rules is to be held at the Charing Cross Hotel on May 2nd, at 1 P.M.

— **TOY PIGEONS.**—A circular is being sent round to fanciers of German Toy Pigeons about the establishment of a Society to promote the breeding and exhibiting of such varieties. It is stated in the circular, that "In addition to this it has long been felt that some definite standard should be determined upon, by which the merits of each breed could be arrived at in a more satisfactory manner." Names of those wishing to become members of such a Society should be sent to Mr. W. H. Marton, 1, Glenfall Villas, Painswick Road, Gloucester.

— **THE MECCHI FUND.**—This fund was started on the death of the late owner of Tiptree Hall, with the view of making a suitable provision for Mrs. Mechi and her daughters, through the instrumentality of the Duke of Bedford, the Earl of Leicester, Mr. Samuel Morley, M.P., Mr. James Caird, C.B., and other influential friends of the deceased gentleman, and now reaches £4400. In order, however, to secure an income to Mrs. Mechi of not less than £200 a year, an additional £700 is required, and this sum the Committee are endeavouring to raise by a further appeal to the general public. The Government, in recognition of Mr. Mechi's public worth both as a spirited and scientific farmer and a commercial man of unimpeachable integrity, have advised Her Majesty, through the Prime Minister, to make a grant of £200 from the Royal Bounty Fund to the subscription that is being formed; and the Dukes of Devonshire and Bedford, the Earl of Leicester, and Mr. Samuel Morley have each contributed £100 to the same object. Other sums varying from £50 to 10s. 6d. have also been remitted from different parts of the country without distinction of class or profession. After Mr. Mechi's death a public meeting was convened at the Mansion House, under the presidency of the Lord Mayor, to testify to the liberality and intelligence with which, before he devoted himself so exclusively to agricultural pursuits, he had served the offices of sheriff and alderman, and the sum of £600 was subscribed for his widow on the spot. Before the termination of his City avocations, however, circumstances connected with the failure of a bank of which Mr. Mechi was a principal director, and to reimburse the creditors of which he voluntarily relinquished a large fortune, had obliged him to resign his aldermanic gown and the honour of the mayoralty in the following year. These incidents in his life, added to the great philanthropic work he carried through in founding and establishing the Royal Agricultural Benevolent Institution, now one of the wealthiest and most important

clarities in the United Kingdom, will, we doubt not, when they are brought to the knowledge of his countrymen, speedily operate in procuring the comparatively small sum still required in the interests of his widow and family, especially when it is remembered that their present destitute position is in a large degree owing to Mr. Mechi's long and zealous attention to matters of public concern. The Marquis of Huntly, Chairman of the fund, and the Hon. Secretary, Mr. C. B. Shaw, will be glad to receive and acknowledge contributions addressed to them at 26, Charles Street, St. James's, London, S.W.

### POULTRY AND PIGEONS

#### ROYAL DUBLIN SOCIETY'S SHOW.

IN consequence of the removal of the Society from the premises in Kildare Street, Dublin, in which their shows have for so many years been held, to the new premises at Ball's Bridge, the usual winter Show was not held. To make up as far as possible for this loss, classes for poultry and Pigeons were added to the schedule of the spring Show, which opened on Tuesday the 19th inst., and lasted four days.

The premises at Ball's Bridge are considerably larger than the old buildings in Kildare Street, and a portion of the spacious gallery round the main hall was allotted to the poultry. The light was admirable, and the substitution of more modern wire show pens for the old wooden ones formerly used was a great advantage. If on a future occasion, as on this, the system of showing pairs of hens together be adopted, it would be better that the pens should be set up at their full width and not narrowed by overlapping the fronts some inches, as they were on this occasion.

It is, we believe, the first time in which the cocks and hens have been shown separately here. This is a great improvement, but we think it was rather a mistake to make the classes for two hens instead of one. No doubt it is a greater test of the real merits of a yard matching a pair of hens for the show pen than merely sending out a single bird, but the system must of necessity injuriously affect the number of entries.

As the season of the year is now somewhat advanced, we do not propose to give a detailed report of the Show, but shall merely make a few notes upon some of the leading birds.

The schedule opened with Silver-Grey Dorkings, which were not so well represented as we have seen them in former years, the cocks especially being deficient in size. The first-prize bird shown by Mr. Shaw was shapely and short in limb, but hardly so silvery in colour as Miss Drevar's, which, however, was not in very good condition. This bird, we regret to say, was very severely wounded in the comb on the second day of the Show, we fear maliciously. There is great want of supervision on the part of the Show authorities in this department; and while upon the subject we may mention that the laxity which prevailed upon the removal of the birds at the close of the Show exceeded anything of the sort that we have seen elsewhere. The gallery was crowded with visitors, and each exhibitor seemed to be at liberty to remove his birds from their pens without the supervision of any responsible person. It says much for the honesty of the exhibitors that the facilities for theft thus afforded do not appear to have been made use of.

The second prize Silver-Grey Dorking cockerel had white in his breast and tail, and should on that account, we thought, have been passed over. The hens shown by Messrs. R. P. Williams and D. Shaw, to which first and second prizes were awarded, were good in size and colour, but still hardly up to what we have seen here in previous years. The Coloured Dorkings were not numerous, but were of very high quality, first and second in each class going to Mr. W. H. King, and third to Messrs. Smyth. The general high quality of the birds may be indicated by the fact that the Palace cup cockerel here, as at Belfast, stood behind a bird bred in the Londonderry yards, but which has now changed hands.

Spanish were fairly well represented, the chief prizes going to Messrs. J. Barlow, Cannan, O'Reilly, and Henry. The birds, however, were as a rule hardly in show condition, which, considering the season of the year, is not to be wondered at.

The Brahma classes were upon the whole far the best we ever remember to have seen in Dublin. In Light cocks Mr. R. Mitchell's bird, which won the cup at Birmingham, here stood second to a large clear-coloured bird of Mr. Cannan, somewhat long in leg and hollow in breast. The Birmingham bird looked smaller and narrower than when we last saw him. Had he been in first-rate condition he would doubtless have stood first. In the hens Mr. Mitchell stood first with his well-known hen mated with a somewhat inferior companion, Mr. C. Graham taking second with a large shapely pair of pure colour fairly matched.

Mr. Mitchell's Dark Brahma cock, first at Hull, Wolverhampton, and elsewhere, here added another to the list of his honours; second going to Mr. Comyns' shapely bird which won the Cambridge cup as a

cockerel and was third at Wolverhampton this year. Mr. Cannan's third-prize bird was of good size, neat in head and good in feather, though a trifle narrow in saddle. The class, which numbered fifteen, contained several other first-class birds which have won their laurels elsewhere. The pair of hens shown by Mr. Cannan were wonderfully short in leg, large and shapely, but were hardly so good in marking as Mr. Comyns' second and third-prize pairs.

The Cochins were strong classes, especially the Buffs. Mr. Cannan took first with a squarely-made, heavily feathered, Lemon cock, very even in colour; and the same gentleman also showed the winning pair of hens, which, however, were hardly so good in colour as the cock. The other prizes for Buffs went to Messrs. Mitchell, C. Brown, and S. Haud; and the first-named gentleman showed a wonderfully fine hen considerably ahead of anything else in the class, but thrown out by being matched with a very inferior one.

In the class for any other coloured Cochin cocks Mr. Cannan stood first and second with large Partridge birds, the former, however, very coarse in comb; Mr. Milner winning the third with a good White. Several other good Partridge birds were shown. Mr. Robertson's winning Partridge hens were shapely and very nicely marked. Second went to moderate Blacks, and third to a pen of Partridge containing one very good bird.

The Game classes, as is usual in Dublin, were not numerous, and contained nothing very remarkable. The chief prizes went to Messrs. Cannan, E. S. Snow, and F. Robertson.

Hamburgs had two fairly filled classes, which were better than one usually sees at this Show. The two firsts went to Mr. Cannan for Golden-spangled, the second for cocks to Mr. J. Aird for Golden-pencilled, and the second for hens to Mr. S. Mowbray for Blacks.

Polish, like the Hamburgs, were all shown together, and, as is usually the case, the Golden had the best of it. The classes were large, and we think might fairly claim a division another year. Messrs. Milner, D. Sullivan, and Cannan won the prizes with large-crested birds, all, however, showing a considerable amount of white in crest. Miss Drevar showed some White-crests, which, however, were hardly as good as we have seen from her yards.

The French breeds were not very largely represented, and the separate classes for La Flèche only produced two entries each. These were shown by Messrs. Field and O'Reilly, and were quite up to the average quality of the breed. Houdans were more numerous, but only of fair quality. Here two prizes went to Mr. Cannan, and the others to Messrs. Field and Rogerson. The first-prize Crève-Cœur cock was a large shapely bird, short in leg and in fine condition, exhibited by Mr. S. Hand. The second prize in this class, as also the first in hens, went to Mr. Cannan for good average birds. The only other pair of hens shown were disqualified on account of their crests being dyed.

In the Variety classes first for cocks was awarded to a good Malay of Mr. Henry, and second to a very neat Brown Leghorn of Miss Brinkley. The class for hens only brought out one entry of Malays.

In Bantams Game alone had classes. These were fairly filled, but contained nothing of very special merit.

The classes for Turkeys and Geese were only moderately filled, but some wonderfully fine birds were shown by Messrs. J. & W. Birch, R. H. Metge, and S. Mowbray, to whom the chief prizes went.

The three classes for Ducks were well filled. The prizes for Rouens went to Messrs. Birch and T. Robertson, the drake shown by the last-named gentleman standing second on account of his great size, although much too light in colour. Messrs. Charley and D. Sullivan took first and second in the Aylesburys, similar honours in the Pekins going to Messrs. Birch and O'Reilly. The bills of the Pekins were hardly as rich in colour as we have seen them.

Pigeons are never very strongly represented in Dublin, as the Society, being essentially an agricultural one, does not seem to think it worth its while to sufficiently encourage these classes. The most successful exhibitors were Messrs. G. A. Kilroy, H. Yardley, W. A. Montgomery, A. G. Shaw, J. H. Hutchinson (whose Trumpeters call for a special word of commendation), Loftie Stoney, A. Jennings, J. Milner, and Mrs. E. Seale, who stood first and second in a good class of Fantails. The prizes were awarded by Messrs. E. Hutton, R. W. Boyle, and J. F. Bomford.

### TOY PIGEONS—ICE.

ICE PIGEONS are not mentioned in the old Pigeon books; even Brent, with his great knowledge of "Toys," only gave a brief account of them. They have been imported from Germany, or at least through German dealers. In form Ice Pigeons are not striking, being very like the common dovehouse bird, though some of the best are feathered on the legs, and then resemble Swallows and Letz in appearance and flight. Their special beauty is their colour, which is mainly a delicate French grey. They have little of the ordinary iridescent breast colour of Pigeons, but appear to be powdered all over like the neck of "powdered" Owls, which gives them a peculiarly soft and frosted look, hence their name. Some are entirely self-coloured without any marking whatever, though there is always some difference of shade between the hard and soft feathers; but the majority are marked, and that in very various ways.

1, The type most usually seen have their wings barred, the

bars being double, of narrow black and white lines—that is, when the birds have their adult plumage, for in their early days such bars are always confused and brown. It is worth while plucking one of the feathers which form these bars to see their beautifully accurate marking. 2, Others have a similar black and white line also across the tail. 3, A third variety have their wings spangled with black and white, their tail and flight feathers are then darker than the rest of their body. Birds so marked are called Siberian or Ural Ice, a fancy name we suspect, and not really connected with their origin. All these three varieties are seen with both clean and feathered legs. There is a little difference of opinion as to the colour of their eyes, some fanciers thinking dark, some gravel eyes the proper thing; our own best birds have had the latter.

Ice Pigeons, like most of the breeds more striking in feather than in form, should be seen in numbers to be appreciated. We once had a considerable flight of them, and the softness of their look when feeding together was very pretty; they contrasted, too, well with our flight of dark metallic-looking Archangels when the two lots were mixed. Ice Pigeons, like other varieties of the dovehouse Pigeon form, are excellent breeders and parents—at least we found them so, and in two or three years raised a considerable stock from a single pair, though we now no longer have them. Well-marked birds can be obtained at moderate prices, and so they are a variety suited to fanciers who cannot afford to begin with birds of the worth of a first-rate Jacobin, Owl, or Turbit. Hitherto at exhibitions they have always had to compete in "variety" classes with almost innumerable other breeds; and consequently we have often observed beautiful Ice Pigeons passed over for more startling novelties, especially the lately imported eastern frilled breeds. If, however, the Society for the Encouragement of the Breeding of German Toys, which we elsewhere notice, should actually be formed we may hope to see classes for this and many other pretty kinds, or at least for groups of them, which have some similarity of characteristics.—C.

### OUR LETTER BOX.

**Buff Cochins** (*Young Gardener*).—You will hardly get birds of any value for the price you name. We cannot recommend you to any particular breeder, as it is contrary to our rules.

**Ducks for Market** (*Idem*).—We cannot advise you to send the ducklings to London unless they are prime birds and well dressed. Can you not dispose of them to advantage nearer home? The Aylesbury trade is a special one carried on by persons who understand the details of the business, and who know to whom they can send their birds with confidence. Single consignments are seldom so well treated as those from regular customers.

**Distinguishing a Cock from a Hen Pigeon** (*Perplexed*).—The cock is bolder, more prone to fight, coos louder, is thicker about the base of the beak and neck. In playing he turns round and round, which the hen rarely does. The hen when cooed to twinkles her eyes, seems to swallow, raises the shoulders of her wings, and curtsies to the cock. Two cocks, also two hens, will occasionally pair, and go through all the actions of a pair as far as possible; but two cocks will also coo after other Pigeons.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

17th.—Very fine, warm, with bright sunshine, throughout; first butterfly seen.  
18th.—Fine, with bright sunshine; cold wind and much dust; high wind at night.  
19th.—Cloudy and cold.  
20th.—Overcast and cold; slight showers of sleet; sunshine at short intervals.  
21st.—Cloudy and cold; occasional very slight showers of snow, and gleams of bright sunshine.  
22nd.—Generally overcast, with bright sunshine at intervals; slight showers in afternoon.  
23rd.—Morning bright and sunny; overcast in afternoon; rain in evening and night.

Temperature much below that of the preceding week. A cold week for the time of year.—G. J. SYMONS.

### CLEMATISES IN POTS.

HERE can be no doubt of the increasing demand for Clematises, and their usefulness and beauty for planting to cover old walls or ramble over ruins and fences, as when in bloom they are unrivalled. Their cultivation in pots as decorative plants appears to be somewhat neglected in private establishments; yet few flowering plants are more effective indoors than these are when well grown, as with a good selection of varieties and judicious preparation of the plants for forcing, a supply can be maintained from February onwards for several months. Where flowering plants for decorative purposes are required in early spring, Clematises should find a place. For room decoration where plants in 8 or 10-inch pots can be employed they are very beautiful, and last nearly as long in light positions as if in the conservatory provided no gas is employed.

Propagation is effected by grafting, which can be readily accomplished. They are worked upon roots, which operation is simple, and with but little experience a number can quickly be obtained. I was told a short time ago that some growers employ roots only from a particular variety, as the scions are more readily worked upon it than upon any other, and succeed much better in poorer soil. The roots from any variety may, however, be employed, and when potting large plants a strong root or two may be taken off each, or if good-sized plants are growing outside it is easy to obtain a number of roots. The old Clematis Flammula produces them freely. Each root must have a few fibres attached, and should be from 6 to 9 inches in length. They can be grafted any time when the wood is young and a little firm, but not too hard. The roots can be kept for a long time if necessary by placing them amongst moist soil or cocoa-nut fibre. Wedge-grafting is the system principally adopted. The scion should have one pair of leaves, and the wood be cut with a sharp knife on each side like a wedge. Split the root down the centre, and place the scion in so that the outer bark of it and the root come in direct contact. Make the scion secure to the stock with matting or worsted and then pot in 2-inch pots, employing a light sandy soil. The roots should be covered rather deeply with the soil, afterwards placing them in a close frame or under hand-glasses where a temperature of 60° to 65° can be maintained. They must be well shaded during bright sun, and be slightly syringed at night: the lights can be lifted and placed down again in the morning. As soon as the scion has become united to the stock more air must be admitted, gradually hardening the plants and exposing them to more light. They can be placed in 4 and 5-inch pots according to the progress

they have made, and when they have commenced rooting in the new soil they can be finally hardened and grown outside. By autumn some of the plants will be as large as those frequently obtained from nurserymen, but as a rule the plants in many nurseries are kept a second year.

My object in describing the system of working Clematises is because amateurs who have a greenhouse delight in raising a plant or two by means of grafting or otherwise. There can be no doubt that they could with a little perseverance soon work a few Clematises, especially if they are in possession of a handlight or two, which could be placed inside their house and be kept close and shaded as directed. The propagation of Clematises does not appear to be so well understood by many gardeners, but in many private gardens there is not the time to devote to such work; therefore, the only course left is to procure them ready worked. If the plants are in 5-inch pots when obtained, and are well rooted, they should be transferred to 7-inch pots. The pots should be well drained, the old drainage being removed and the roots disentangled. This operation will cause no injury, as they are strong-rooting plants. Potting is best done a short time before the plants are started into growth. A shift into a larger pot every year according to the progress they have made is sufficient until they are placed into 10 or 12-inch pots, which are large enough for decorative purposes. When in the last-named size annual potting is still recommended—that is, by removing a portion of the old exhausted soil, renewing the drainage, and again placing them in the same sized pot with fresh soil. The soil cannot be too rich; good rich loam, a third of decayed manure, and coarse sand to render the whole porous will suit them well. While growing Clematises require liberal applications of water at the roots, and in no stage should the soil be allowed to become very dry. When the pots are full of roots stimulants can be liberally supplied.

After potting, if the plants are placed in a temperature of 45° to 50° they soon commence growing. The young plants should be supported with an upright stake, and if convenient be placed so that their growth can be trained under the roof of a plant house. If strings are taken from the centre support and secured to the roof of the house, and each young shoot trained to them, the growth will be more rapid, and ripen better than if trained round four or five stakes in the pots. When the wood is nearly mature the shoot can be tied to stakes and the plants placed outside, where they may be allowed to remain until the approach of frost, and then be protected in a cold frame or house.

The earliest-blooming varieties of the Patens section—of which Lady Londesborough is the type, one of the freest, earliest, and best for forcing—will, if gently started at the commencement of the year, produce a few flowers in the spring. This season the plants should produce a number of growths and advance rapidly if these are again trained to strings as directed for the first season. At the close of the second season they can be trained upon small balloon-shaped trellises. This section furnishes the most varieties suitable for pot culture, especially for early flowering during February, March, and April. Most of the varieties flower profusely, and require no pruning, as the flowers are produced on the previous year's wood. There is but little difficulty in inducing plants to flower early; one or two seasons' early starting is sufficient. Our plants this season commenced growth in a cold frame

towards the end of November. The following varieties are arranged in the order they flower:—Lady Londesborough, Standishii, Miss Bateman, Albert Victor, Lord Londesborough, The Queen, Sir Garnet Wolseley, Fair Rosamond, and Sophie flore-pleno; the two last are not very free with me, but distinct and worth growing.

The Florida section contains many that succeed well in pots, but are not so free as those mentioned above, except Fortunei, a double white sweet-scented variety, John Gould Veitch, and Luey Lemoine.

The Lanuginosa varieties—some of which produce enormous flowers (for instance, Henryi and Lawsoniana)—would do well in pots for later blooming, and the size of their individual flowers compensate for them not being produced in such numbers as the others.

The Jackmanni forms are, in my estimation, best adapted for outdoor planting or late autumn work in pots, and should be subject to pruning, whether in pots or planted out.—WM. BARDNEY.

#### A DEEP RICH LOAM.

WHAT is a deep rich loam? It is a soil of great fertility, consisting largely of clay with smaller quantities of quartz and sand, and a considerable proportion of decomposed vegetable matter. It has been defined as "a soil compounded of various earths;" and the definition is a good one, eminently calculated to encourage those who are struggling with the difficulties arising from a poor soil which they hope to improve by repeated dressings of manure, and whatever else may be available that is calculated to impart fertility and a sufficiently close resemblance to a rich if not a deep loam. This is an arduous undertaking, but without the slightest uncertainty, for the condition of the crops and the general results obtained yearly afford the clearest indication of the condition of the soil; and if the work of improvement be rightly carried on, each year should witness a distinct and marked advance.

In the selection of the site for a kitchen garden the nature and condition of the soil are almost as important as the situation. The appearance of anything found growing upon the land generally affords some indication of its state of fertility, but in all doubtful cases we ought not to rest content with anything short of actual analysis. In proof of this I may give an instance of one of my own blunders. Some years ago, having to make a Vine border and stations for fruit trees in a poor thin soil, I had to look about for the best soil within a reasonable distance. In a valley hard by a stream of water I found a large deep bed of dark red soil—so deep that a pole could be thrust down into it some 15 feet, and a strong rank growth of grass seemed to show ample proof of its richness. No hesitation was felt, therefore, in using this soil for the required purpose, in full confidence of successful results; and certainly for a time all went well, both Vines and trees growing with remarkable vigour and freedom in the broken sods of the turfy top spit mingled with some of the red ferruginous soil taken from the deep bed beneath it. But in due course the fictitious fertility imparted by the decaying turf became exhausted, and then the poverty of the soil became apparent, for despite liberal top-dressings of rich manure there was an annual falling-off in the condition of the Grape Vines, except in one border originally made very shallow by way of experiment, so that the roots were able to reach and spread freely in the top-dressing of manure. In the deep borders the root action was weak and sluggish; for despite an abundant admixture of bones, the soil contained the elements of fertility in so trifling a degree that the roots first attracted into it by the turf gradually perished, only a few being found alive when it was eventually removed.

The compost used to renovate the deep Vine borders is a singular one, consisting of anthills chopped up and mixed with some old well-decayed dung, bones, and mortar rubbish. Such fine anthills I have never before seen; they had probably been sixty or seventy years in construction, many of them being a yard in diameter and nearly 2 feet high. Talk of upland loam! what soil was ever so admirably aerated and sweetened as this? It was a spongy mass abounding with grass roots, and the colonies of ants might be numbered by tens of thousands, forming in themselves no mean addition to its enrichment. Sufficient soil was taken up and mixed with the anthills to correct any undue tendency to lightness, and I anticipate excellent results from it.

Reverting to the original soil of the border, I very well remember two gentlemen calling upon me while it was being carted from the valley—one of them famous for the quantity and quality of his Roses, and the other almost equally so for his Pine Apples. Both

exclaimed that they should like to have such a soil for their favourites, and both may be assured that they have no reason to regret that their wish remains ungratified; for it was subsequently discovered that this soil of so tempting an appearance and so soft in texture that it crumbled lightly at a touch, consisted absolutely of silt brought down during storms by the flooded waters of the stream from the uplands and deposited in the hollows and flat spaces of the valleys. It had probably laid there for hundreds of years, and had gradually acquired its dark red hue from an ochreous deposit of spring water slowly percolating through it from an adjacent bog. I am aware that alluvial soils formed in this way are generally very fertile, but in order to be so they must consist very largely of particles of rich soil or vegetable matter, but in this instance the principal element was the poor silicious soil of Ashdown Forest.

A deep rich loam is generally to be found in perfection in very old kitchen gardens rich from the culture and care of several generations of gardeners. To would-be improvers of such a soil—and there are such—one may well inquire, What are you going to do? and how do you propose doing it? Take away some of the old soil and replace it with upland loam, as I once heard gravely suggested? Why you might as well offer gold for silver, or old lamps for new ones! Rather, much rather, guard and keep every particle of the old soil; stir it deeply, throw it up roughly in ridges early in autumn, so that as much of it as possible may be exposed to the influence of winter; dress it freely with lime fresh from the kiln if it prove at all sour or inert, and bountiful crops will be obtained.—EDWARD LUCKHURST.

#### BRIEF NOTES ON PLANTS.

COOL Orchids have only one fault, and it is a serious one with the great majority of gardeners—they cannot be readily propagated; consequently they are too expensive even at the cheap rates for which many can now be purchased. Many owners of gardens object to paying more than a few shillings for a single plant, and some gardeners have the same feeling. A fixed sum is paid every autumn for spring-flowering bulbs, which are regularly thrown away after they have borne a crop of flowers. Why should not an equal amount also be spent annually on Orchids, which, if expensive at first, are always increasing in value and usefulness?

Mr. Taylor's method of striking cuttings of softwooded plants is a very good one. I have employed a similar system for the last two or three years, the only difference being that I do not take any trouble to exclude air. Ordinary boxes are employed, and after the cuttings are inserted as thickly as possible two large panes of glass are placed over each box. The boxes are placed on the pipe in a forcing house, and thus Lobelias and Iresines strike in three or four days without any loss. It is, however, necessary that the plants from which the cuttings have been taken should have been grown in heat.

Our Alternantheras did not pass the winter well, and in order to raise a stock of healthy plants for propagating later on all the cuttings which could be had were taken and inserted. They died in scores, and it was not until others were inserted, and which damped off at the soil level in the same manner, that the cause was discovered. The sand used, instead of having been laid up for two or three years, was fresh from the seashore, and directly the plants and cuttings were transferred into other sand the losses were stopped.

A note on Pteris tremula was inserted in a late number of the Journal. I find it one of our best "cutting" Ferns. P. serrulata and its crested forms are also of great service for cutting from, while one of the best decorative Ferns is to be had in P. longifolia. Another useful species is Polystichum proliferum, of which small plants are sold extensively in the Edinburgh markets. These are all common, easily grown, and of the greatest value from a decorative point of view.

This spring our plants of Richardia æthiopica were placed on a vinery border, as being the only suitable position which could be found at the time. To protect the border from the water escaping from the bottom of the pots a large saucer was placed under each, and as a consequence we have secured from two to three times as many spathes as we did when saucers were not used. The difference is quite astonishing. The plants are regularly supplied with chemical manures, and the saucers may have been useful in retaining these.—R. P. B.

BIRDS AND FRUITS.—The benevolent notion that wild fruits are always provided in increased quantities as a provision for the small birds in a hard coming winter, has this past season been

dispelled in a rather rude fashion, as may be gathered from the following notes: In 1880 nuts of all kinds were scarcer by far than we ever remember to have noticed. Whitethorn was unusually shy in flowering, and consequently in fruiting, haws thus being conspicuous by their absence. Sloes fruited very slightly indeed, which is curious, as it was by no means a bad year for Plums. Indeed, but for these the poor wasps would have had but a sad time of it, as Apples, Pears, and wall fruits were far from plentiful. The only hedge plant that bore even a moderate crop of berries was the Privet, which could hardly have been designed to eke out the food of the small birds, as but very few of these care for Privet berries.—JAMES BUCKMAN (in *Science Gossip*).

### GRAPE HYACINTHS.

SEVERAL of the beautiful little bulbous plants included in the genus *Muscari* are among the oldest of introduced plants now grown in gardens, and are still favourites wherever they are known. Clumps of these are often seen in old gardens, where they are rarely disturbed except to keep the fast-spreading species within suitable bounds, and in such positions flowers are produced so freely as to prove useful for cutting, supplying shades of blue that can be scarcely equalled when the flowers are at their best, as the *Scillas* are then nearly over. I have memories of Grape Hyacinths grown in large beds which in April and May formed masses of the loveliest blue tints, invoking the admiration of all who saw them. Unfortunately they are now rarely seen in such profusion except in a few nurseries, and then the formal lines in which they are planted detract from their beauty. They are certainly to some extent neglected, but why it is not easy to discover, as their culture is simple enough to enable anyone to grow them satisfactorily wherever a moderately sheltered position and a light rich soil can be afforded them, and there are few gardens in which these requirements cannot be provided. By growing the bulbs in pots excellent results can be obtained, for if placed in a frame during the winter flowers are produced several weeks before the plants outside are in bloom. When treated in this way they are extremely useful for arranging in the greenhouse or conservatory, a few pots of *M. botryoides* and the white variety being charming in the front row of plants on the side stages in such structures. Another good quality the *Muscari* possess is the readiness with which they can be increased; in fact some appear to spread too rapidly in particularly favourable positions, and then a little difficulty is experienced in restricting them to their proper quarters. However, this is more the exception than the rule. When it is desired to increase the stock the old bulbs should be lifted, the young offsets being removed and planted in fine soil, where they will grow quickly and soon reach flowering size. Except for this purpose it will not be found necessary to disturb the beds very often unless the plants become crowded, as they flower more freely and vigorously when they are well established. Some of the most beautiful species are briefly described in the following notes.

*M. botryoides*.—One of the old forms that were known to Gerard, Parkinson, and other writers of the sixteenth and seventeenth century. It is an early-flowering species, bearing globose bright "skie coloured" flowers in comparatively large racemes usually about 6 inches in height, the narrow leaves being of similar length. There are several varieties, some considerably larger than the type; but the best is the white form *M. botryoides album*, which has neat racemes of white flowers, affording a pleasing contrast with the ordinary blue form, especially when grown in pots as advised above.

*M. comosum*.—Another long-known species, rather stronger-growing than the last, frequently reaching a foot in height, and with long racemes of purplish blue flowers. Parkinson describing this among the other forms observes, "The whole stalk with the flower upon it doth somewhat resemble a long purse tassell, and thereupon divers gentlewomen have so named it." It is, however, chiefly remarkable for the extraordinary variety known botanically as *M. comosum monstrosum*, and popularly as the Feather Hyacinth. This bears a large plume-like raceme of flowers, the corollas of which are cut into long narrow divisions, imparting a peculiar and yet graceful appearance to the plant.

*M. racemosum*.—This is the most commonly seen *Muscari*, for it is one of the cottagers' favourites, at least in some districts, where there is scarcely a garden without it, nearly rivalling in abundance another common but much-appreciated plant in small gardens, the Thrift. It is known as the Starch Hyacinth from the peculiar odour of wet starch which the flowers possess. These are borne in compact racemes 6 inches or more in height, and are of a deep bluish purple tint.

*M. Szovitsianum*.—A comparatively modern introduction in-

cluded in the same section as the foregoing species—namely, the true Grape Hyacinths, or the *Botryanthus* section of the genus *Muscari*. It has a very compact raceme 6 inches high, with bright blue globular flowers; the corolla having six small tooth-like divisions, which are white, and agreeably relieve the fine blue tint of the other portion. This succeeds admirably in pots; and the specimens recently exhibited by Messrs. Osborn & Sons of Fulham at Regent's Park and South Kensington were greatly admired by many visitors; and it was remarked that among all the beautiful plants shown on both occasions there was not one which possessed flowers of such a bright and pure blue colour. At the Fulham Nursery the plants are grown planted out in a border with the other species, and the accompanying woodcut represents one of these of the average size.

Near these are several recent introductions that are as yet but little known, and chiefly confined to the large collections of hardy plants and bulbs. One of the best is *M. Heldreichi*, with a

Fig. 79.—*Muscari Szovitsianum*.

conical raceme of bright blue flowers; it is rather dwarfer than *M. Szovitsianum*. *M. armeniacum* has fine dark purplish blue flowers in a large compact raceme; it is one of the darkest coloured forms. *M. neglectum*, also very dark blue, almost black flowers, in a large raceme. *M. conicum*, *M. compactum*, *M. pallens*, and several others are all more or less pretty but rare. One form is grown by Messrs. Osborn under the name of *M. commutatum*, dwarf, with small light blue globular flowers in a neat raceme. It is very pretty, but I do not think it is the *M. commutatum* described by Mr. Baker, as that has darker flowers and is of stronger growth.

*M. moschatum*.—This, though very distinct from the other Grape Hyacinths, and much less attractive in colour, deserves notice for the powerful and to some persons very agreeable musky odour it possesses. The flowers are long, not globose as in the other forms, more suggestive of the *Lachenalias* in form, and the colour

is greenish yellow with a few tints of red. It is an old species, having been described and figured by Parkinson in his "Paradisus" under the name of "*Hyacinthus Botroides major moschatus*, the Great Yellow Muske Grape Flower," which he states is "very sweete in smell, like unto Muske, whereof it took the name Museari." A few potfuls of this in a greenhouse are very acceptable.—L. C.

#### WALLFLOWERS AND SWEET WILLIAMS IN POTS.

**WALLFLOWERS.**—These are always appreciated when they appear in the open, and they are so easily cultivated that the poorest as well as the richest may have them in their gardens. But the object of our writing is to let it be more generally known how well they are adapted to pot culture, and how well they are suited for room decoration during the early months of the year. Sweet-scented flowers are always welcome at any season, and none more so than the Wallflower. We sow the seed in May on a warm border; as soon as the seedlings are large enough they are pricked out on a piece of good ground about 9 inches apart each way. They are lifted and potted in the autumn. If they are then placed in a house or pit where a temperature of about 45° or 50° can be maintained and never allowed to become dry, they will make good plants, and will flower about the beginning of February without any forcing. The double German forms are very fine when well grown, but for sweetness the single varieties are not surpassed.

**SWEET WILLIAMS.**—I find these very useful when grown in pots. Treated in the same way as Wallflowers, they can be had in flower about the same time. When properly treated they require no staking, as the flower stems are as stiff as when grown out of doors. We raise them from seed in the same way as Wallflowers; but when a good variety is obtained it is advisable to propagate it by cuttings, which will be found to root freely on a warm border.—LEADENHAM.

#### CHISWICK IN MAY.

It is long since the Royal Horticultural Society's Gardens were so beautiful as they are now. Every year during the fruit-blossoming period the numerous trees of various forms and sizes which constitute this great collection are more or less attractive, but this year the wealth of blossom is so great and the flowers are so fine that the effect is particularly imposing. The Pear trees especially are densely clothed in silvery drapery, forming pyramids of purity that no ornaments of the pleasure ground can surpass. Last year Pear blossom was comparatively sparse, many trees being nearly destitute of flowers. This year the reverse is the case, there being very few trees that are not crowded with blossom, and some of these are instructive. For instance, on one side of a walk we find a grand pyramid Jargonelle 10 or 12 feet high and 6 feet in diameter at the base, with branches so strong that no wind can move them, wreathed from base to apex with large blush flowers, while a tree of the same variety, and identical in age, form, and size on the opposite side of the walk, is flowerless. The fruitful tree is on the Quince stock, the barren tree on the Pear. The superiority of the former stock is most striking, the tree being equally stout in stem, clean, and healthy with its barren neighbour "over the way." This Pear is considered difficult to train in the form of a handsome pyramid, but the examples referred to are as near perfect as anyone could wish. The flowers, too, of this variety are amongst the finest, being very large. Splendid, too, in this respect is a variety named Belle Henriette: beautiful indeed is this tree—a huge bouquet, and the appropriateness of the name as applied to the flowers cannot be questioned. Henri Capron compels a pause, being about equally fine; and similarly striking is the valuable autumn Pear Belle Julie, the merits of which as a certain bearer combined with excellent quality is not yet sufficiently appreciated. During recent bad years this tree has been remarkable for its heavy crops, and yet it is, if possible, more richly draped with blossom than ever. Near it is Urbaniste, with insignificant blossom, but this is not an index of the fruit it bears, which is fine. Beurré Hardy is one of the grandest pyramids in the garden, perhaps excelling in this respect Beurré d'Amanlis and Maréchal de Cour, which are models of fertility; while Deux Sœurs is one of the latest, and singular as being the only variety having flowers tinted with pink, like Apple blossom. Such trees as those are quite capable of bearing a bushel of fruit each. There is a large plantation of Pears similar to those alluded to, some of the trees being 10 feet high and more that have been planted six years. They are 8 feet apart, or say at the rate of seven hundred trees per acre. In a good fruit year such culture could not fail being

profitable, especially as the ground between has been and will continue to be also utilised by other crops. True, such trees need pruning, but grown as they are with branches about a foot apart and nearly as thick and strong as the shaft of a spade, the outlay in this respect is really trifling, as, in fact, trees thus fertile make but little superfluous wood. It is quite impossible that anyone who has produced such trees as these could say anything against the system of culture, even from an utilitarian point of view; and no amount of theory—nothing short of actual results, can avail in attempting to show that any so-called natural, or rough-and-ready mode of culture, would be more profitable during the period indicated from the time of planting.

The secret of having such fine trees consists in not shortening the leaders closely, but allowing them to remain as far as the wood is ripened. Few and strong side branches are then produced, not numerous and weak growths, which characterise thousands of trees grown on the pyramid system and which have not proved satisfactory. The principle of growing such trees as those under notice may be described as extension of the leader as long as such extension is needed, and thinning and restriction of the side branches, so that every leaf is fully exposed to the light and air. This is true culture, scientifically sound and practically successful, as the trees bear substantial witness.

Adjoining this fine quarter of Pears is another quarter, mostly of Apples. A freer mode of culture has been adopted here, for all plans are fairly tried at Chiswick. "Try all modes fully, fairly, and without prejudice," might be the motto there—at any rate it is practised if not proclaimed—"and judge by results;" or, as the Americans tersely and significantly would put it, there are "no axes to grind." It must be said that these wild trees that have not been pruned lately do not compare favourably with the others; their spreading branches cover much more space, and many portions are destitute of spurs. No cropping can be done amongst the trees, while if all the flower trusses could be counted they would be far less in number than on the trees that have had better attention and occupy less space. And further, the "let alone" trees will soon all be ruined if every alternate specimen is not cut out, the same has been done in a large commercial fruit-growing establishment in the same district. In fact, these are not suitable trees for gardens, though it is right they should be grown at Chiswick for educational purposes; but there are plenty of trees that are most appropriate, handsome, and profitable for garden culture, and those who denounce the culture of them with "a sweep of the pen" might do worse than pay a visit to Chiswick during the ensuing week.

There are sturdy columns 9 feet high and 18 inches in diameter at the base that need no stakes nor other form of support, that take up no more room than a good Savoy, nor half so much as a Gooseberry bush, yet are crowded with blossom as if covered with snow. Are they out of place in a garden? It may be stated with a considerable amount of confidence that nine hundred people out of a thousand who had such trees flanking their garden walks would not think so. Then there are the vertical cordons 5 feet high, rigid as Hollyhock stakes, and crowded with flowers from the ground upwards. These trees are planted about 18 inches apart, which affords free access to light and air to each, yet as in bloom they form an almost close fence, not occupying a width of ground of more than a foot. This is a beautiful screen of flowers now, far surpassing in this respect a row at right angles of the ordinary horizontal-trained espaliers, though not a word is said against the usefulness of the latter mode of training trees for gardens. If a fair proportion of the blossoms on these sturdy and self-supporting verticals sets—and it will not be the form of the trees that prevents its setting—the ground occupied of, say, a foot wide and 100 yards long will be more remunerative than the same space occupied by any other garden crops that may be planted on the same space of ground near the trees. Yet "fruit trees are not fit for gardens" says some bold man or big man; and forthwith there are hundreds of smaller men who, parrot-like, follow suit, and the refrain rolls on and round, those who have never seen such trees as these quite believing there are no fruit trees fit for gardens; yet not one per cent. of them who had these trees in *their* gardens would, it may safely be said, hasten to root them out. "But the time they take root-pruning and knife-pruning!" some lover of Nature may exclaim. Let them not be startled when it is stated as a fact that they have very little of either. Summer-pineching has been the mainspring of the fertility of the trees, and there are larger trees on walls that have never been root-pruned, and which need next to no knife or winter-pruning, and which, although the branches are vertically trained, are like ropes of flowers from the ground to the top of the wall. Such trees show in the most convincing

and conclusive manner the influence of summer-pinchings in promoting fruitfulness. But the fertility of the several forms of trees referred to is not wholly due to any manipulative process, as undoubtedly the stocks on which the trees are grafted have contributed of their influence, and this is great.

The various stocks are submitted to the fullest and fairest possible trial. This is the time of year for observing the results, as the flowers are the real test of fertility. An accidental occurrence may prevent a tree bearing fruit even after its fruit-bearing capacity has been proved by its blossom. There are stocks that have never been worked nor pruned. All are of the same age, but of different sizes and degrees of fruitfulness. The free or Crab stocks are fruitless, the different varieties of Paradise stocks showing their distinct features of habit and fertility. The French Paradise has proved its character by dying; when not grafted it cannot live long, but when an Apple is worked on it the tree lives for at least a number of years, and fruits heavily—clear evidence of the scion influencing the stock. All these stocks are also grafted with the same variety of Apple—Blenheim Pippin—which is not a precocious bearer nor of close bush or pyramidal growth; yet the precise characteristics of the several stocks both as to habit and fertility are clearly portrayed in the trees, affording the most striking evidence of the influence of the stock over the scion.

It is not necessary to detail the condition of all the stocks, as four of them will be sufficient for all practical purposes—the French Paradise, the Doucin, the Broad-leaved Paradise, and the Crab. The first is the dwarfiest and the most precocious of all, and for purposes of comparison its height may be given as 3 feet, every part of the trees being laden with flowers; the second, the Doucin, is a foot or more higher, proportionally stronger, and bearing about the same number of flowers more thinly disposed; the third, the Broad-leaved Paradise, is over 5 feet high, with, in comparison, few flowers, yet sufficient for a good crop of fruit; the fourth, the Crab, is over 6 feet high, strong and not producing one flower—the Apple, as before stated, being in every instance the Blenheim Pippin. There are two trees representing each stock, and each is an exact counterpart of the other.

If space permitted some practical lessons might be deduced from this instructive and fairly conducted and valuable experiment; but it can only be briefly and broadly stated that if an acre of Apple trees were planted on either of the first three stocks according to their special adaptations to the soil, and another acre of trees on the Crab stock were planted, and a series of good fruit years were to follow, the produce of the former—the profits—would buy the land before the other would pay the rent; but estimating their relative values over a period of a quarter of a century the very dwarf stocks would probably be nowhere, although even under this test it is highly probable that the freer growing but not rampant Broad-leaved Paradise would be as profitable as the Crab. But the stock trials do not end with the examples quoted. There are rows of young trees on the Paradise and Doucin stocks, a dozen or more of several varieties of Apples being worked respectively on the two stocks. The difference is most marked and perceptible at a glance, the Doucin being in every instance the stronger; while if the tedious process were gone through of counting the thousands of flowers on these two-year-old trees that have never been pruned, the difference in all probability would be very slight.

The Pear trees on different stocks are similarly instructive. A number of Winter Nelis have been growing for years on all sorts of stocks that could be utilised. Whether the trees have been pruned or not the results are the same. Those on the Pear are either barren or sparse of blossom, those on the Quince crowded; some very fine trees worked on *Crataegus coccinea* combine strength with fertility, but a number on other "fancy" stocks are of no practical utility.

It has been said that all the forms of growing fruit trees are adopted at Chiswick. That, however, is not quite accurate, and Mr. Barron might do worse than give an object lesson showing the manner in which so many trees are rendered fruitless by injudicious management and incorrect pruning. He might plant strong trees on free-growing stocks, prune them severely for a few years until a large number of branches were struggling with each other for light; allow these branches to grow during the summer and cut them off in the winter, not thinning them too much; let the roots alone, so that they might be able to incite and support luxuriant growths another year; these to continue growing all the summer and cut off in winter as usual, and so on from year to year; thus showing, as was once stated in this Journal, a fine example of growing flower stakes instead of producing fruit. This is the way in which too many trees are treated,

and disappointment engendered. A system of fruit culture is then denounced because of the injudicious manner in which it was carried out. With a little labour well and intelligently applied the same trees might have been fruitful—a source of pride and profit to the owner during favourable seasons for fruit. At Chiswick the right plan is shown, and it would be seen, if possible, to greater advantage if the wrong were represented in juxtaposition. Far better is it for those who have not the necessary time nor skill for bestowing the proper attention on the trees to simply thin out these branches and allow them to extend, and some Pears, but not all, will form natural fruit spurs, handsome pyramids, and valuable crops of fruit. Apples similarly managed will not form pyramids, but fruitful bushes or bush trees, more or less spreading according to the habit of the variety; but these trees are not fit for gardens, while hundreds of specimens at Chiswick are admirably adapted for this purpose.

Besides the Pear blossom in the garden that is so profuse and fine, there is an excellent show of Plum and Cherry blossom, and the Apple trees will shortly be as richly laden as the Pears. The blossom being a fortnight later than the average period of expansion, and a month later than in early years, and not yet blackened at the core, affords reasonable ground for hope that fruit will follow; but unfortunately violent hailstorms and severe frosts are always liable to occur during the month of May and bring destruction in their train. Let us hope it will not be so this year, for a golden harvest would be a blessing to all.

There is much more that is noteworthy in the gardens, but all that can be done at present is to advise all who have the means of doing so, that desire to see the beauty of Nature combined with the skill of man, to pay a visit to "Chiswick in May," and the sooner the better.

#### PROVINCIAL FOLK LORE.

SOME time ago you were obliging enough to review in these columns a little book of mine entitled "Provincial Folk Lore." I inserted your remarks in a second edition. These have been lately re-reviewed in the January number of the "Westminster Review" for 1881. As this is a famous year for both Cherry and Plum tree blossom it may be interesting to reproduce what is said, and may possibly draw forth some further elucidations. "The author misses his way in his remarks on the familiar south-country rhyme—

"A Cherry year  
A merry year;  
A Plum year  
A dumb year."

This, we are told on the authority of a writer in the *Journal of Horticulture*, means that 'Cherries are never plentiful except when their blossoms have a genial spring and summer, and that an abundance of Plums carries an increase in the death rate.' Now 'this interesting explanation,' as the author calls it, is like the definition of a crab by the French scientific world, utterly wrong in every particular. The word 'merry' has nothing whatever to do with our adjective so spelt, but is connected with the French *Merise*, and is a common provincialism throughout the south-west of England for the wild Cherry (*Prunus avium*). In Hampshire 'Merry Feasts' are still held. The learned authors of 'English Plant Names' further remark that there are various kinds of 'Merries' known as red, black, and white, in different parts of England. The word 'dumb' has also nothing to do with the adjective so spelt, but is a corruption of Damson (*Prunus communis*). The meaning of the rhyme now becomes apparent. It simply says that a good year for Cherries is also a good year for 'Merries'; and that a good year for Plums (always spelt 'plumb' by the rustic of the west of England, and so making a purer rhyme) is also a good year for Damsons—that, in short, the year which is favourable to cultivated is also favourable to wild fruit."

The wind-up of this critique, I humbly opine, is hardly equal to the first part. It leaves me in the state of mind described after certain law pleadings—

"Mr. Parker  
Made that darker  
Which was dark enough without."

Here my memory fails, but I can supply the ending—

"And the Chancellor said, I doubt."

—ALAN CHEALES.

*YUCCA ALOIFOLIA VARIEGATA*.—I recently noticed a remarkably healthy specimen of this fine decorative plant in the intermediate house at Oakville near this town. Although introduced to this country more than a century since, and grown at the Glasnevin and College Botanic Gardens, Dublin, it is too seldom

found in private collections in Ireland. It is said to be hardy, but the foliage could scarcely be as fine as under glass. That it enjoys considerable moisture is proved from its location here near a miniature fountain and artistic reservoir.—W. J. M., *Clonmel*.

#### ROSES AT SOUTH KENSINGTON.

A FEW notes, especially on the newer varieties that were exhibited at the last meeting of the Society, may not, perhaps, be unacceptable to your readers, at least the numerous rosarians who regard the Journal as almost an official organ on all that concerns the queen of flowers. But before I enter upon my theme I must add my word of approbation to the chorus of praise which greeted Mr. Boscawen on his exhibiting such a magnificent specimen of the fine old Orchid *Cattleya Skinneri*. Mr. Boscawen brought this *Cattleya* three hundred miles, travelling all night, and reaching South Kensington just in time to stage his plant, which so worthily won a silver Flora medal, and many of us thought it deserved a gold one. But after all there is nothing like the Rose, and the splendid collections staged by Messrs. George Paul and

to be a good grower. Charles Darwin also took my fancy, being grand in form and bright as to colour at an early stage; but as the buds open fully the colour becomes dull and cloudy, and the Rose falls off sadly. Ferdinand Chaffelle is no gain in any way, while Paul Jamain and Edouard André are both good. Madame Eliza Taissor is an ugly expanded flower, thin in the centre. Mdlle. Julie Dymonier is a lovely Rose, pale flesh in colour fading off to pure white. It reminds me of that old Rose rarely if ever seen now, Louise Magnan, being globular in form and good in every way. Comtesse de Choiseuil has a very good form, but does not stand the sun and appears to be a bad opener, but in the bud is superb. Gloire de Bourg-la-Reine has a good deep colour, but is very thin. Mr. Paul also showed two seedlings unnamed, one of which pleased me much, being of a deep rose colour, having a grand globular form, somewhat in the way of Madame Clemence Joigneaux as to colour. The other seedling did not take my fancy.

Messrs. Veitch exhibited a beautiful collection of half-standards in pots, which were much admired. I was surprised to find what a beautiful pot Rose Mrs. George Paul is, also Olga Marix, which out of doors is worthless. Madame Lacharme, the Tea Madame Maurin, Catherine Mermet, a bloom of which last-named in my opinion was the finest flower in the Show, and Emily Laxton were all very good, and the collection as a whole highly interesting to rosarians.—WYLD SAVAGE.

#### OXLIPS.

HAVING read in your Journal many letters respecting Oxlip, Cowslip, and Primrose culture, I think it may interest some of your readers to learn the result of an experiment I have tried. In the autumn of 1879 I found some pods of seed on an Oxlip plant which had never before produced seed, and as soon as ripe I gathered them and sowed the seed in a pan. A number of seedlings soon appeared, which I pricked off into a large box as soon as they were large enough. In the spring of 1880 I planted the seedlings, which I found numbered about one hundred, into a bed of ordinary garden soil. A few bloomed the following autumn, producing Primrose flowers both yellow and pink. The plants grew to a large size, and this spring have all bloomed freely with the following result—Fifty-four ordinary Primroses of various shades of yellow and pink, thirty-nine producing bunches of Primrose blooms on a high stem, in the way of Polyanthus—these also contain many shades, some very rich crimson; six red Cowslips, but not one of all the number resembles the parent Oxlip.—ROSEWARNE.

#### EXTENSION-TRAINED PEACH TREES.

I AM pleased to see your correspondent and my old "mate," Mr. Pettigrew, recommending this system. I am not one who is going to maintain that it has never been practised before, but Mr. Pettigrew does not, according to his own admission, "go the whole hog" in the matter. He pinches off the laterals, but leaving them is an important part of the system, and it is the only way to dissipate the over-luxuriance of strong shoots and extend the tree rapidly. I would just remark, too, how singular it is that when anyone brings out a new, or supposed new idea, there should always be so many who have, unbeknown, been practising exactly the same thing for, say, half a century or thereabout. Up till the period when I published my account in all the papers of setting Muscat and other Grapes in a minimum temperature of 50° and lower, it was an accepted idea taught by the most noted authors, that a temperature of from 70° to 75° was the secret of setting Grapes, and in every calendar those figures were given; but no sooner had I written than there were ever so many claimants to the low-temperature system, who had never, some of them said, adopted any other practice! Yet they had permitted writers to go on from time immemorial almost to recommend the very opposite, and had never once opened their mouths. And now, although there is not a work on gardening where the extension system of Peach culture is advocated or described, it is discovered that numerous friends and others have been going on with the same all their lives, but they have only just found courage to say so. It is of course, quite possible that a gardener living at John o'Groat's and another living at the Land's End may be carrying on similar practices, but when one does not know what the other is doing, and finds no mention of his opinions or practices in the numerous gardening periodicals and books, he may be excused for thinking that such practices are not common, and it need not "amuse" a gardener of experience and information to discover as much.

PERMIT me to thank you for your fair and impartial review of

Fig. 80.—*Nepenthes compacta*. (See page 355.)

James Veitch well repaid those who journeyed to Kensington on the chance of seeing their favourite flower. Besides fine examples of older varieties Mr. George Paul showed what is much more interesting—a collection of new or comparatively new Roses. These were small plants and had not many blooms on them, so that my judgment may not be based on very good premises; but I examined the blooms carefully and did my best to form a correct estimate of their merits.

First there was Souvenir de Victor Verdier, a good Rose of a deep rich colour, somewhat in the way of Horace Vernet. Then came Comtesse de Mortemart, which in my opinion is bad in every way; while Jules Chrétien was a splendid bloom, globular in form and grand in colour, as was also Madame Ducher, H.P. It a little resembles Madame Furtado in form and exactly in colour, and appears

my book, and to ask you to kindly allow me to offer a short explanation regarding one or two points raised by the reviewer. He expresses the opinion that if the Peach tree which I planted in 1866 "exists now it would have been well if the author had published a photograph of it." This fact I have all along fully realised myself, and the thing would have been done had it been practicable. I had the photographer here repeatedly with that object, but owing to the tree growing in a lean-to house and under a fixed roof it could not be photographed. First I would have had to remove the roof, or at least all the sashes, as owing to the slanting roof and reflection from the glass the tree could not have been taken; and even after the roof had been removed some scaffolding and much necessary and expensive preparation would have been needful to get the camera placed at right angles to the

tree, so as to show its actual area. Besides, being an early house I dared not uncover the house at that season. These are reasons why a portrait of the tree was not given. The tree, however, "exists," and is perhaps as fine a specimen in its way as could be shown; and, pardon me for saying it, its present condition completely belies the assertion that the "ultimate results of 'Nature's plan' is to increase the nakedness of the branches, and, of course, of fruit towards the base." The tree is a living contradiction of this. Up till two years ago this tree had only a lateral extension of 15 feet, owing to my being compelled to keep a Nectarine in the same division; but these past two years it has had the whole space to itself, and has doubled its size in that time on the extension principle, and it is now 32 feet wide and 18 feet high, and carries a fine crop; and a Nectarine in the next division is nearly

Fig. 81.—*NEPENTHES COMPACTA*.

the same size, and carries an even greater crop. Mr. Fowler of Harewood, who was here the other day, and whom I asked to look at the tree through the glass, in order to see the shoots better, said "he never saw a better-furnished tree." With regard to Vines, perhaps you will allow me also to point out that it is not the quality of the Grapes that the system of extension seeks to improve, but to produce Vines and crops in far less time than is done now—i.e., "quick returns" without impairing the quality of the fruit. I would also point out that I do not condemn "pruning," as your fourth paragraph from the end might convey, and I am aware they prune their trees in America, but not in one case in a thousand probably on the restrictive system. I have near relations engaged in fruit culture in America possessing orchards 1000 acres in extent, and I understand "Nature's plan" is the one followed principally by all cultivators, except that the branches are occasionally thinned out.—J. SIMPSON, Wortley.

P.S.—The trees that are shown grow on an upright trellis,

curved at the top, and the lights, being loose, were taken out for the photographer's convenience.—J. S.

#### NEPENTHES COMPACTA.

THIS is one of the numerous beautiful Pitcher Plants which have been sent out from the Holloway nurseries in recent years; and in the compactness of its habit, and the freedom with which the richly coloured elegant pitchers are produced, it may be favourably compared with any in commerce. It is in the way of the handsome and useful *N. robusta*, and its chief characters are well shown in the accompanying woodcut, kindly lent us by Mr. B. S. Williams, who describes the plant as follows:—

"This very distinct variety has pitchers about 5 inches long and 8 inches in circumference, the primary markings being reddish purple, sometimes shaded with violet, splashed and marbled with creamy white, with margins and mouth of the same colour, the

lid beautifully spotted. It is a compact-growing variety, with a profusion of pitchers, and has been awarded a first-class certificate by the Royal Botanic Society."

#### EUPHORBIA JACQUINIÆFLORA AND POINSETTIA PULCHERRIMA.

THOSE plants that bloom in winter are very much appreciated, as then good flowers are scarce, and the above two are amongst the most beautiful. I have classed them together, as they both require similar treatment. They are generally seen with rather tall stems, and they are then not so well adapted for decorative purposes. The best time I have found to insert the cuttings is the middle of July; if the old plants are started about three weeks previous, they will have abundance of shoots suitable for cuttings, which should be taken off with a piece of the old wood attached. Insert the Poinsettias singly, and the Euphorbias three in a small 60-pot. Place them under a handlight in a close moist heat. When rooted place them in the house, and repot rather firmly into 48-sized pots, employing two parts fibry loam, one of leaf soil, and one of peat, with enough leaf soil and sand to keep the compost open. Place a little charcoal over the drainage, as I find they are rather partial to it. Keep them close till they are established, then harden them off and transfer them to a cold frame close to the glass, remove the lights in the evening, as the plants delight in the night dews. Ventilate the frame freely in the day, and shade from bright sunshine. About the end of September or beginning of October place the plants in a warm, light, airy house, and when the Poinsettias commence showing their bracts give a little liquid manure.—A. YOUNG.

WE have the pleasure to announce that the Right Hon. Lord Aberdare, President of the Royal Horticultural Society, will preside at the next annual dinner of the GARDENERS' ROYAL BENEVOLENT INSTITUTION, which will take place on the 6th of July next.

— WE are informed that at the NATIONAL AURICULA SOCIETY'S NORTHERN SHOW, reported last week, the prizetakers for Fancy Auriculas were Mr. S. Barlow first, and Mr. Bolton second, no third stand being staged. Mr. H. Brownhill was first only (not second and third) with twelve Polyanthus, and Mr. Brockbank was also only first with twelve Primroses, no other stand being exhibited in either class.

— AT the last meeting of the Royal Horticultural Society Mr. R. Veitch of Exeter obtained a first-class certificate for RHODODENDRON EXONIENSE, a beautiful hybrid between R. ciliatum and R. Veitchi, both of which it resembles in some characters. It is noteworthy for its compact habit, bright green leaves, and bell-shaped crisped flowers, which are white faintly tinged with pink, and 3 to 4 inches in diameter.

— MESSRS. RICHARD SMITH & Co. of Worcester exhibited some plants of the pretty and useful DAPHNE FIONIANA at the recent Spring Show in Birmingham, and there was scarcely another group which attracted more attention from the visitors. We are not surprised at this, for a plant that has been sent to us from Worcester is laden with charming rosy flowers deliciously perfumed. The plant is one of the best hardy Daphnes in cultivation, and it is surprising it seems so little known, for either in pots or borders it forms an excellent addition to any garden. The flowers are of a pinkish hue, closely clustered on the branches, and possess a most agreeable and powerful fragrance. The plant was formerly known under the name of D. versaillese, having been the result of a cross between D. Cneorum and D. collina effected by M. Fion, whose name it now bears. It

is usually grafted on one of the common species, such as D. Mezereum or D. pontica, and dwarf compact plants are readily obtained, which flower freely during the early spring months.

— "B." writes—"There is now to be seen in the Camellia house in Croxteth Hall gardens a very fine plant of RHODODENDRON DALHOUSIÆ covered with its large campanulate fragrant flowers measuring 4 inches in length and as much in diameter. The flowers as they first open are of a pale amber colour, changing to pure white. It is surprising these lovely Rhododendrons are not more grown, especially in conservatories where they can be planted out. In the same garden the double Cinerarias now in flower are the finest examples I have seen, the flowers being large and very full. Mr. Barham propagates them by means of offsets, which they produce very sparingly."

— MESSRS. EWING & Co. of Norwich have sent us a few fruit of NORWICH PROLIFIC NUT with the following note:—"The few nuts herewith enclosed are some that were put aside and forgotten in the autumn of 1879, and came to light the other day during some house-cleaning operations. We think, considering that they have been all the time in a dry closet, it is a severe test of their keeping quality." The kernels of the nuts, though much shrivelled, were quite sound and of excellent flavour, quite equal to those of the Lambert Filbert under similar conditions.

— WE are requested to state that seedling Pelargoniums may be submitted to the PELARGONIUM SOCIETY for the honorary award of certificate of merit on June 14th, June 28th, and July 12th. Intending exhibitors must give three clear days' notice on forms provided for the purpose. These may be obtained from the Honorary Secretary, Mr. Shirley Hibberd, 15, Brownwood Park, London, N.

— THERE is now on view at the Alexandra Palace an EXHIBITION OF CLEMATISES in pots from Messrs. G. Jackman & Sons' nursery, Woking. Many excellent varieties are represented in good condition.

— A DAILY contemporary in an article advocating the extended culture in India of the MAHWAH TREE (BASSIA LATIFOLIA), has the following remarks upon the mode in which the crop is collected—"The flowers come to maturity towards the end of February or beginning of March; and the corollas, becoming fleshy with secreted juices, gradually loosen their adhesion to the calyx and fall to the ground. The duty of collecting the crop is chiefly performed by women and children, who generally remain under the trees all day, alternately collecting the fallen blossoms and sleeping, the male members of the family visiting them once or twice a day to take away what has been collected. In cases where the trees are a long distance from a village a temporary encampment is often formed, in which they live till the whole crop is secured. A first-class tree, it is said, will continue to shed its blossoms for fifteen days, at the rate of 100 lbs. a day, which weight is reduced by one-half in the process of drying. A maund (80 lbs.) of dried Mahwah will furnish a fortnight's food to a family of two parents and three children. It keeps good a long time, and is generally eaten with the seeds of the Sal Tree, or with the leaves of jungle plants, a small quantity of rice being sometimes added."

— A CORRESPONDENT, "C. M.," referring to the notes that have appeared in our columns on PELARGONIUMS FOR WINTER FLOWERING, expresses his surprise that "John Gibbons" (scarlet), and Captain Holden (rosy plum), have not been included in the list. He found them very useful last winter, both varieties having flowered freely in an ordinary greenhouse quite out of reach of the sun's rays from October till March. Both are old varieties raised by Mr. Pearson, and our correspondent has proved their usefulness when many other Pelargoniums were not in bloom.

— MESSRS. CASSELL, PETTER, & GALPIN have sent us the following parts of several of their SERIAL WORKS. "Paxton's Flower Garden," part 9, containing coloured plates of *Rhododendron A. B. Mitford* and *Medinilla magnifica*, the latter rather pale in tint, and woodcuts of *Trichosachme lanata*, *Calanthe vestita*, *Steriphoma paradoxa*, and *Aspasia lunata*, with accompanying descriptions. "Familiar Garden Flowers," part 27, gives coloured representations of a Zonal *Pelargonium* and *Cuphea platycentra*; part 50 of "Familiar Wild Flowers" having similar plates of the common Tansy and the Hedge Stachys. The most satisfactory portion of both works being the cultural and historical particulars concerning the plants figured.

— THE annual report for the past year of the JAMAICA PUBLIC GARDENS, by Mr. D. Morris, the new Director, is one of great interest. As the year has been the first under the new organisation the chief work has naturally been of a departmental character, but from the details given it is evident that important advances have been made in developing several industries which must have an important influence for good on the future of the island. From the variation in altitude of the different gardens under Mr. Morris's charge excellent opportunities are afforded for experimenting on various kinds of cultivation, and these he is evidently prepared to take full advantage of. Among the various cultures, concerning which interesting information is contained in the report, are Cinchona, Liberian Coffee, Sugar Canes, Teak and Mahogany, Pine Apples, Jalap, Cacao, Tobacco, Indiarubber, various spices, Oranges, Banana fibre, &c. The best results may be looked for from Mr. Morris's vigorous and intelligent directorship. There is also a very satisfactory report of work for the year ending March 31st, 1880, from Mr. Duthie, Superintendent of the Government Botanical Gardens at Saharanpor and Mussooree. As in Jamaica, experiments, some of them very successful, have been carried on in the rearing of various useful plants, including vegetable and medicinal plants. Much difficulty has been experienced by Mr. Duthie in training Mallies for work in the gardens, and he has some trials before him ere he is able to turn out a staff of properly trained natives.—(*Nature*.)

— "VICK'S MONTHLY MAGAZINE" gives this description of a PERFUMERY FARM IN AMERICA:—"A flower farm has been started at Carpentaria, Santa Barbara county, California, with buildings suitably fitted up with laboratory and stills for the purpose of extracting the essential oils for the sake of the perfumes of the flowers. The fields are described as acres of Tuberoses, English Violets, Jessamines, and Orange blossoms. First on the list of perfume-bearers is the Provence Rose, our dear old 'Cabbage,' or Hundred-leaved, which has lost none of its ancient charms, yet has been supplanted by Roses of deeper and purer tints, or by the Tea Roses which are so inexhaustible in their variety and beauty. Mr. Hall obtains his stock of Roses and Jessamine, as well as the Bitter Orange, in the south of Europe; of the latter he has several thousands of trees. Two weeks ago (January) the Tuberoses were still in perfection—a field of ten thousand!"

— THE "Journal of Applied Science" has the appended remarks upon MELON CULTURE IN AMERICA:—"Missouri boasts of possessing one of the largest and most productive Melon patches in the United States. It is situated on the borders of Scott and Mississippi counties, and equals if it does not exceed in size and adaptation of soil and climate the famous Melon patches of Georgia, Indiana, and the eastern shore of Maryland. It is described as a tract of sandy prairie, four miles wide and ten miles long, with a thin warm soil, just adapted to the cultivation of the Melon, and such Melons as are raised nowhere else in that region. There is much richer and deeper soil all around, but it is not adapted to Melon culture. This land is capable of producing one

thousand Melons to the acre. As Diehlstadt, in Scott County, there were shipped the past season 439 carloads of 1000 to the car; and Bertrand, in Mississippi County, shipped 180 carloads, mostly to Chicago. The Melon county was visited by twenty-five commission merchants from Chicago, who paid as low as 40 dols. and as high as 140 dols. per carload, being an average of 70 dols. per car, the market price varying with the advance of the season and the number of Melons ripening at the same time. Most of these Melons were shipped over the Cairo and Vincennes and Illinois Central Railroads in fruit cars, properly ventilated for the purpose. Melons are becoming such a staple of production that the cultivators are asking for increased railroad facilities to move the product at the proper season, representing that they would plant 700 acres more next year if the railroad will give them a side track and station three miles north of Charleston, to be called Melon Station. It is estimated that 700 acres ought to produce 700 carloads, at the rate of 1000 Melons to the acre, making 700,000 Melons. One man can attend to 25 acres. The variety used is the Georgia Melon, which is very luscious and grows to a great size, some weighing 60 lbs. The hills are planted 14 feet each way apart, and from three to four seeds are put in a hill. They commence shipping Melons about the 20th of July, and continue to the end of August."

#### WOODLAND WALKS.

I READ with great interest the articles on the above subject which appeared in your Journal last year. They were particularly attractive, not only because they were written by your correspondent "WYLD SAVAGE," but also because the subject was unusual and novel. The articles, which dealt mainly with the formation, &c., of walks and drives in woods, must have been beneficial to all the gardeners. Horticulturists may be in danger of becoming too much attached to straight lines and faultless curves, or they may allow the trained gracefulness of our gardens and conservatories to entirely eclipse in their minds the beauty of the modest plants which give a charm to our hedgerows. I think that a truly scientific horticulturist should pay some attention to the decoration of our woodland walks and brook sides.

Many walks and drives in parks and in various parts of our estates are almost destitute of flowers, either from the walks having been newly formed, or from the poverty of the flora of the neighbourhood. Can we not improve the flora of our districts? This most desirable object may be attained by planting roots or by sowing seeds. Many kinds of bulbs are most suitable for this purpose. As simple instances I may mention *Scilla siberica*, Snowdrops, the various kinds of *Narcissus*, all of which if planted in favourable positions will increase and bloom year after year. Scores of other suitable plants will suggest themselves to every practical gardener. For stony rocky neighbourhoods many plants are suitable which can readily be obtained.

My object, however, in writing is to advocate the plan of sowing seed of such annual, biennial, and perennial plants as are likely to reproduce themselves. Everyone should sow plenty of *Myosotis alpestris*, as it will grow almost anywhere, and will produce an abundance of its blue flowers year after year. Seedsmen now offer a mixture of the best varieties of annuals which are selected as suitable for improving the natural flora, the seeds to be sown broadcast in the most favourable positions. It is wise to avoid sowing under the dense shade of trees; if possible the position should be moderately moist, and have the benefit of moderate exposure to the sun. The seed should be sown without any previous preparation of the ground in such places as the sides of streams, hedgerows, and sunny spots in the woods. If sown in showery weather in May it will be sure to succeed. Mixtures of suitable seeds may be obtained at very reasonable prices.—VINDEK.

AUSTRALIAN PLANTS IN INDIA.—Mr. G. Bidie of Madras recently communicated to *Nature* the following notes upon Australian plants in the district of the Nilgiri plateau, in South India, at elevations ranging from 5500 to nearly 8000 feet above sea level:—"Acacias and Eucalypti in particular have found a congenial home in this region, and visitors from Australia who have seen them say that they appear even more vigorous than in their native soil. Hundreds of acres of *Eucalyptus globulus* and of *Acacia melanoxylon* and *A. dealbata* have been planted by

Government as firewood reserves, and the trees have grown up splendidly. The only drawback to the success of the experiment has been that the *Acacia melanoxylon* has been greatly injured by Lorantheous parasites; in fact, this species will apparently in course of time be exterminated by these indigenous pests. Besides *Eucalyptus globulus* the following species of the genus have also been introduced and thrive well:—*E. sideroxylon*, *E. obliqua*, *E. fissilis*, *E. rostrata*, *E. viminalis*, *E. amygdalina*, and *E. perfoliata*. In addition to the two species of *Acacia* already mentioned the following have also been added to the list of healthy-growing exotics on the Nilgiris—viz., *A. pycnantha*, *A. salicina*, *A. longifolia*, *A. decurrens*, *A. cultriformis*, *A. elata*, and others might also be enumerated. As regards other Australian plants on these hills we have *Hakea*, *Banksia*, *Myoporum*, *Kunzea*, *Tristania*, *Pittosporum*, *Beaufortia*, &c. In short, there is a very considerable Australian flora flourishing on the 'Blue Mountains' of Madras, and so extensively have the trees been planted out about the principal stations that they have given quite a new character to the scenery. Some of the *Acacias* have a considerable resemblance in shape and colour to the Scotch Fir, and this likeness has, to some visitors, added a fresh charm to the beauties of the scenery."

#### EPIDENDRUM BICORNUTUM.

AMONGST the numerous species of *Epidendrum* there are many that are not really worth cultivating, though in such an extensive genus we might expect to find many species that would be worth a place in any Orchid collection. This is by no means the case, though a dozen good sorts could easily be found that would please most cultivators, and the one I have chosen for my subject should certainly be included.

*Epidendrum bicornutum* is rarely seen even in large collections, and the reason is, that it is an Orchid which has baffled the skill of most growers to cultivate satisfactorily. It is undoubtedly the finest species of its genus, and in colour and general appearance it will bear comparison with *Phalaenopsis amabilis*; it is a little smaller, but that is more than counterbalanced by the delicious perfume its flowers possess. The best way to grow it is in baskets suspended from the roof, or on pieces of Tree Fern stem. I have grown and flowered it under both systems, and if grown in baskets a compost of very fibry peat, moss, and charcoal should be employed. The plant roots freely in its natural habitat, but is rather shy-rooting under cultivation. The plant is a native of the West Indian Islands, particularly Trinidad, consequently it requires the temperature of the East Indian house. Having a friend living in Trinidad, I wrote him for particulars with regard to where it was found and under what conditions, and, as it may interest some of the readers of the Journal, I will give his reply as I received it. He writes, "With regard to your questions respecting *E. bicornutum*, if I tell you how I collected it no doubt that will suffice. I went out one day last week, hired a boat to carry me to the Five Islands, a group of irregular size, standing at no great height out of the water, in one bend or basin of our harbour, which may be called rocks left after the severance of that part from the mainland by the encroaching influence of the sea. Round these islands one can sail and soon load his boat by pulling the tufts off the ledges of the rocks or any cavity. It is subject to drenchings of water by the action of the waves, is generally fully exposed to the sun, and as it is surrounded by water the plant must be subject to heavy dews owing to the great variation in temperature of the land at night. I soon collected a load, though I am afraid they are too much advanced in growth for travelling."

By these remarks the readers of the Journal may easily perceive that the three most essential requirements of *E. bicornutum* are heat, exposure to sun, moisture, and a moderately low night temperature, and if these be carefully attended to it should make satisfactory progress. Any trouble bestowed on it will, I am convinced, well repay the cultivator, for when once seen the blooms cannot fail to be appreciated. The imported pseudo-bulbs average about 9 inches in length, they are hollow and of a dark brown colour inside. At the base of each there is a small cavity or opening, through which insects, and more particularly ants, find their way and make their nests in them.—W. K.

#### THE BLACK CURRANT.

SINCE the publication of the notes on "Fruit Growing for Market," wherein Mr. Luckhurst refers to an article in vol. xix., page 97, of this Journal, the demand for that number has been so great that the whole of the issue has been sold; and as many applicants have been disappointed in obtaining the number, we

now by request reprint the article, which was communicated by Mr. Luckhurst in 1870.

Of all the kinds of bush fruit grown for the markets, the Black Currant is undoubtedly the most profitable. Its easy cultivation, the vigour with which it grows in almost all soils, and its great fruitfulness are all points in its favour. It flourishes in the cold Wealden clay, in which but few other fruit trees will thrive, and it is considered poor soil indeed in which the Black Currant will not grow; nor is its crop so much affected by being shaded during its growth as that of other fruits would be, for most flourishing plantations of it may be seen growing around and under standard trees.

But while all this may be said in its favour, it must also be granted that it is a gross-feeding plant, increasing in vigour in proportion to the quality of the soil, and it will well repay the fruit-grower for all the manure he can bestow upon it. Some little care is, however, necessary in regard to the way in which manure is applied; no practice can possibly be worse than to dig in manure in the way in which it is sometimes done, the fork going into the ground so deeply as to tear off quantities of the young roots, thus doing more harm than good. This deep culture may answer very well when the plants are young, but as they attain a larger size, and the roots gradually spread farther and farther, manure is best given as a top-dressing or in a liquid state.

In propagating the Black Currant it is a common practice to leave a clear stem of nearly a foot in length; now this is not only unnecessary, but is altogether a mistake, as it is impossible for such trees with their long stems to continue to produce such fine fruit as others, the branches of which spring from the ground erect and strong, and whose vigour and size is constantly increased by the sturdy suckers springing up and taking the place of the older wood.

As an example of what can be done with such bushes, I may instance two fine rows of Black Currants growing in the gardens of the Earl of Romney. These bushes are upwards of twenty years old; they were planted 6 feet apart, but have grown with such vigour that, notwithstanding the freedom with which they have constantly been pruned, they are now 5 feet high, and the side branches of every tree touch those of its neighbour. Nothing can exceed the robust appearance of these splendid bushes. The soil about their roots has not been disturbed for some years past, with the exception of being deeply hoed on the surface a few times in summer, in order to work in the annual top-dressing of hotbed manure. In favourable seasons the fruit crop averages four gallons on each bush; this year it will not be so good, as the crop has suffered from the late spring frosts.

The sight of these large bushes, which from the vigour of their young growth appear likely to flourish for twenty years longer, and the large crops of fine fruit which they produce, are enough to set one thinking; and after making a calculation of the value of their produce at the rate of 4d. per quart, as given by "A LANCASHIRE SUBSCRIBER," in No. 470 of this Journal, so enormous is the total, and so much in excess of what it is customary to speak of, that one hardly likes to put it on paper. However, here are my facts, and I would ask all growers of fruit for profit to give them the notice they deserve. An acre of such trees planted 6 feet apart will contain 1210 plants, and taking the crop at 4 gallons or 16 quarts per bush, at 4d. per quart, we have the astounding sum of £322 13s. 4d. per acre. Now, I do not pretend to say that an acre of Black Currants has ever produced such a crop, but here we have forty-two bushes growing side by side, the yield of which has been up to this average in every favourable season for some time past, and therefore there can be no reason why an acre, or many acres, of such trees should not be capable of producing some such desirable results.

And this leads to the inquiry, Why is it that such fine Black Currant trees are not more frequently to be met with? It may be that the answer is contained in the fact that the hardy and accommodating nature of the Black Currant causes it generally to be planted in poor soil and in an equally bad situation, and so it is very rarely indeed that the requisite conditions are afforded to enable it to attain its fullest development.

Now these conditions are few, simple, and easily understood. Large juicy fruit always commands the best sale. Such fruit is only produced on the young vigorous growth of the preceding year; it must, therefore, be our aim to obtain an abundance of such wood by planting in a deep rich loam, by manuring freely, and by cutting away the old and thinning the young wood, so as to admit air and light. Such being the case, it must be admitted, that while no fruit tree is so useful as the Black Currant for planting in poor soil, yet none thrives better or yields such rich returns when enjoying the advantages of a good soil and generous treatment.

#### SOLANUM VENUSTUM.

THIS beautiful plant deserves to become better known in the horticultural world, as it merits a place in any stove for training to the roof, and then its fine pendulous panicles of soft lavender or mauve-coloured flowers can be seen to the best advantage. When in good condition it somewhat resembles *Petrea volubilis*, especially after the calyxes of the latter have fallen; and it is also suggestive of its ally, *Solanum jasminoides*, which, however, thrives in cooler quarters. Its treatment is simple; a good turfy

loam and a moderate proportion of sand with a little well-decayed manure constitute a compost that suits it admirably. The plant

if well treated grows fast, and will need occasional pruning to keep it in shape; but the best way is to train the branches up the

Fig. 82.—*Solanum venustum*.

roof and allow the shorter flowering shoots to hang down in festoons, as it appears much more graceful in that manner than when cut-in too closely.

The spray I send is cut from a comparatively small plant, but its parent was, I believe, the handsome specimen in the Palm house at Kew, which has been there some years, and frequently produces a fine display of flowers. A very good figure of that was published in the "Botanical Magazine" some ten or twelve years ago, when Sir Joseph Hooker stated that the origin of the plant was not certainly known, but it was believed to be a native of Brazil.

I am not sure if the plant is in commerce, but if not it might advantageously receive the attention of nurserymen. The woodcut shows the foliage

and form of the panicle very well, the flowers being about half the natural size.—R. L.

#### FRUIT PROSPECTS.

I SEE some of your correspondents entertain a very hopeful view of the fruit prospects. I should be sorry to unnecessarily cast a cloud over their hopes; but have they taken anything more than a superficial view of the case? According to my observations the trees are flowering freely, and will probably continue to do so for some time; but as far as the Pear crop is concerned the flowering is a complete delusion, for not only are the blooms which are expanded killed as far as fruit-bearing is concerned, but I grieve to say that in most cases the later and unexpanded flowers are also fatally injured, and if cut through the centre will be seen to be black. This will not prevent the flowers expanding and looking as beautiful as ever, thus creating fond hopes doomed to disappointment. Some of the varieties have suffered less than others, and those on the walls I am in hopes will have sufficient left in most instances for a light crop. Half the Plum blossom on walls is killed, but I think there is sufficient left for a crop. Dessert Cherries on walls are more injured than Plums, but Morellos are safe so far. Peaches, strange to say, have suffered less than anything and are swelling an abundant crop, although covered only with a coarse net such as is used to keep birds away. Apples are safe with the exception of two or three early-flowering varieties; but orchards about this neighbourhood, being mostly old, have never recovered from the effects of the cold wet summer of 1879, followed by the severe winter.—WM. TAYLOR.

NATIVE FLOWERS.—I was agreeably surprised the other day by seeing in a plantation on a hill having a west aspect the

yellow Star of Bethlehem (*Gagea lutea*), in abundance and flowering freely. I find this plant very useful in borders or pots at this season, and it ought to be more generally grown. What, too, can be more beautiful at this season than *Anemone nemorosa* and its charming companions the Strawberry-leaved Cinquefoil (*Potentilla Fragariastrum*), the Sweet-scented Violet, and the ever-welcome Primrose, *Primula vulgaris*?—VERNA.

#### MARÉCHAL NIEL ROSE AND BOUGAINVILLEA AT MR. JOHN SCOTT'S.

IN my last letter I endeavoured to give a short description of a garden where there were no flowers to cut or plants suitable for the adornment of rooms. Happily all places are not in this plight, and one of the pleasantest half hours I have had lately was spent among the flowers in the garden belonging to John Scott, Esq., at Warminster. I endeavoured to time my visit so as to see two remarkable plants of Maréchal Niel Rose in bloom. I daresay I have told your readers before that I have no great liking for Maréchal Niel except in certain positions, the best of which is immediately under the roof of a greenhouse, where we can look up and enjoy the wonderful shading visible in the interior of this Rose as well as the beautiful outline of the nearly expanded flowers. It is true that this variety when grown in the ordinary way has its beautifully rich colour to recommend it, and it is also very floriferous, but it requires a great stretch of the imagination before we can say its shape is beautiful, unless we take the Sugar-loaf Cabbage as a model; but covering the roof of a house and exhibiting hundreds of perfect flowers at one time, suspended in the best possible position to show all the beauty without showing what I call the defects, and having an abundance of its glossy green and wavy foliage as a background to check the glare of the sun and enhance the beauty of the colouring, is a picture which, although it is a fortnight since I saw it, is not likely to be soon forgotten. The two plants are on Briars with 4-feet stems; they have been in their present position several years and have always done well, and as the stocks are still swelling freely there is every prospect of their continuing to gratify their owner and his visitors for some time to come.

I understand that the growth made at the time of flowering and immediately after is not productive of bloom; much, therefore, of this is thinned-out, after which the plants start afresh, make long vigorous branches, which retain their foliage through the winter and produce flowering shoots at every axil in spring. The results produced year after year testify to the wisdom of this practice. In the same house were many plants in bloom arranged on a stage along the centre and on broad shelves along the sides and one end. Among them were Camellias, Azaleas, Cyclamens, Pelargoniums, Cinerarias, and Amaryllises, all in vigorous health and carrying abundance of bloom.

In another little house was a plant in flower on the roof even more remarkable, and quite as beautiful as the Rose just mentioned. This was Bougainvillea splendens, and it was a perfect sheet of colour. I suggested that the small yellow flower in the centre of the coloured bracts was a hint that the Bougainvillea and the Maréchal would look well together as cut flowers; but I found Mrs. Scott had already anticipated me, and I had the pleasure of admiring a vase containing the two arranged by that lady, and I must say that I was not disappointed with the effect. I have often been puzzled to know what to mix with Bougainvillea, and in the end have generally put it up separately. The only one I grow, however, is *B. glabra*, and I am not certain that it would go with the Maréchal so well as the one in question does. Mr. Scott's plant is in a large pot, but its roots protrude through the bottom and ramble amongst some rubble forming the bed, on which are grown a quantity of Ferns and some Orchids; so it will be seen its fate cannot be said to be rich.

I think I have already made it plain that, whatever may be the case elsewhere, there is no flower famine at Mr. Scott's; and as this gentleman is the most successful of our local Rose exhibitors, and has occasionally taken high honours at some of the great shows, I need hardly say that he generally has something fit to cut, if it is only a Rose; and I can hardly imagine a garden which would give more pleasure to its owner than the one concerning which these notes are written.—WM. TAYLOR.

[Our correspondent probably refers to Bougainvillea spectabilis in the above notes, and not to *B. splendens*, which is synonymous with *B. glabra*.—ED.]

**ELECTRICITY AND THE VINE.**—The influence of atmospheric electricity on the vegetation of the Vine has been studied near Palermo by M. Macagno (*Jour. de Agr. Prat.*) thus: Sixteen

stocks were rendered more subject to the effects of the electric tension by means of a copper wire inserted vertically with platinum point in the upper end of the fruit branch, while another wire connected the bottom of the branch with the ground. This continued from April to September. An acceleration of vegetation was proved by the wood of these stocks containing less mineral matters and potash than that of the other stocks, while the contrary occurred in the leaves, and in these the potash was mostly in the bitartrate form. A much greater quantity of must was got from the Grapes of those Vines, and it had considerably more glucose and less acid.—(*Nature.*)

#### ODDS AND ENDS.

SUBJECTS not insignificant, and yet not deserving more than a paragraph heading, I have often thought might be usefully treated of under the above heading, and others might be prompted thereby to record their experiences in a similar manner; so, in pursuance of this idea I forward a few notes.

*Schizostylis coccinea*.—A fine plant for decorative purposes and for cutting from in autumn and early winter. It should be grown through the summer in pots plunged in an open yet sheltered but sunny situation in ashes, well supplying it with water and weak liquid manure. Plants in 8 or 9-inch pots will produce from eighteen to two dozen spikes, and brighten up a greenhouse or conservatory wonderfully at the dull season. Small plants may be grown in 6-inch pots for decorative purposes. Plants should now be taken from the ground and potted, or those in pots divided, employing either turfy loam or fibrous peat, as they do well in either.

*Anemone japonica alba*.—The fine large pure white flowers of this are beautiful in late summer, and useful for cutting, and the plants thrive in the borders until frost comes. They may, however, be grown in pots, strong plants being now lifted and potted with some fresh compost—turfy loam with about a fifth of decayed manure. Plunge the pots in ashes, supplying water and liquid manure freely during summer. Strong single crowns now potted in 7 to 9-inch pots will make useful flowering plants by autumn.

*Hellebores*.—"Christmas Roses" are very uncertain in the open borders, and they should be grown in pots, which is a more advisable plan than lifting in autumn. By shifting as required into larger pots very fine specimens may be secured, which have an imposing appearance in conservatories, and the flowers are valued for cutting. They should be hardened off before placing outdoors in spring. Slugs are very fond of the flower buds, and must be guarded against with lime or soot. Rather strong turfy loam is the most suitable compost, and good drainage is essential. *Helleborus niger maximus* is a fine early form of the species. *H. angustifolius* is a very floriferous form of *H. niger*. *H. orientalis* is more stately, and affords foliage as well as flowers at the same time. *H. olympicus* is similar, and very free. These are common, and are often not accorded the attention their usefulness and decorative value claim for them.

*Forced Strawberries*.—Vicomtesse Hericart de Thury has not been satisfactory in the earliest-started batch; the fruit neither set nor swelled freely. Under the same conditions La Grosse Sucrée had some fine fruit, one average fruit outweighing three of the Vicomtesse. Evidently the latter cannot bear so much forcing in the early stages as La Grosse Sucrée, as the second batch was all that could be desired. Black Prince has been discarded for early forcing, as it is subject to mildew, and the fruit is small. Pioneer is also subject to mildew, but its fruit sets well, and is of fine conical form. Keens' Seedling is a capital early variety, but it gives more small fruit than La Grosse Sucrée. For mid-forcing President stands pre-eminent, and for late use Dr. Hogg. Sir Joseph Paxton is always attacked by mildew. Sir Charles Napier when in its best condition is one of the finest, and for an imposing appearance James Veitch is excellent. Sir Harry is readily forced, and equally good is Wonderful and Marguerite, though the latter is not deep enough in colour for some.

*Peach Blossom Setting*.—The idea that artificial impregnation to secure a good set is not necessary, may receive a check from the circumstance that I purposely omitted to resort to any of the approved means of artificial impregnation with Royal George, the very best forcing and surest setting Peach known, and with the result that the fruit set very badly; whilst in the same house Barrington, one of the worst setters under glass, Roman Nectarine, Grosse Mignonne, and Bellegarde Peaches, with Violette Hâtive Nectarine under precisely the same treatment, set well with artificial impregnation. Where there are bees, or the weather is so bright as to admit of ventilation back and front, the disturbance of the air may affect the distribution of the pollen quite

as well as shaking the trees, liberating it with a plume of Pampas Grass, or applying it direct to the stigma with a camel's-hair pencil, but it clearly does not answer to leave matters of this kind to chance.—G. ABBEY.

#### HABROTHAMNUS ELEGANS.

If I were asked to name two plants for climbing in a greenhouse or conservatory the above would be one of them. We have a large bush of it covering a pillar in the conservatory here, and no plant with which I am acquainted surpasses it in production of flowers. This plant has been in bloom since the middle of December, and the supply shows no signs of exhaustion. It has been no ordinary supply either, as every time cut flowers have been wanted, and that has almost been daily, the Habrothamnus was never missed; and it is probably owing to this that it has flowered so profusely, as the oftener it is cut the more lateral growths are produced. Its culture is most simple, the chief requirement being abundance of nourishment at the roots. It succeeds much better planted out in a bed than in a pot, although in the latter way it also grows and flowers freely.

It is easily propagated by cuttings, which should be inserted at once where a little bottom heat can be afforded them. As soon as rooted pot them off singly, and when growth has commenced plant them out in a greenhouse or conservatory in good loam, half-decayed manure, and a little sand. Plants so treated will produce many of their bright crimson flowers throughout next winter, and after that they will very rarely be out of bloom.

Trained to a wall this Habrothamnus soon covers a large space, and it succeeds better in a shady corner than any other of our greenhouse plants. The flowers are highly ornamental in either large or small vases, as small twigs can be had for the latter, and long racemes many feet in length for the former.—J. MUIR.

#### COMING HORTICULTURAL EXHIBITIONS.

WE have received a number of schedules of various horticultural societies; the following brief particulars of which, with the dates at which the exhibitions are to be held, may be of service to some of our readers.

Last year an exhibition of plants, fruits, and vegetables was held at Turnham Green, and proved so satisfactory and successful that it has led to the establishment of a local society under the name of the Chiswick, Turnham Green, and District Horticultural Society. The first Exhibition of the new Society will be held in the Royal Horticultural Society's Garden, Chiswick, on July 14th, when prizes amounting to about £100 will be offered in fifty-two classes for plants, cut flowers, fruit, and vegetables. Subscribers are entitled to several season tickets of admission to the Royal Horticultural Society's Garden, varying in number from one to four in proportion to the amount subscribed. Mr. A. F. Barron is the Hon. General Manager, and Mr. J. T. Musgrave, Sutton Court Road, is the Hon. Sec., from whom schedules and particulars may be obtained.

It is announced that the Kingston and Surbiton Royal Horticultural Society will hold the seventeenth annual Exhibition on Wednesday, July 13th, in the grounds of Bank Grove, Kingston, the residence of C. J. Freake, Esq., when the usual liberal prizes will be offered in numerous classes. Several special prizes are also offered, the chief being those given by the President, H.R.H. Prince Leopold, for a group of plants; by Sir Trevor Lawrence, Bart., for table plants; and by Lady Peek for cut flowers and vegetables. The report for the past year announces a small balance to the credit of the Society. The amount awarded in prizes was £98 13s., against £69 16s. in the previous year, while there was a slight falling-off in the subscriptions considered as due to the Committee not having been able to earlier announce where the exhibition would be held.

As usual the schedule of the Richmond Horticultural Society enumerates classes for all the chief kinds of garden produce. Plants, flowers, fruit, and vegetables are well provided for, the prizes offered being liberal and numerous. In the three divisions devoted to the Society's prizes sixty classes are named, the prizes ranging in value from £8 (the first prize for nine stove and greenhouse plants, the chief class in the Show) to 2s. in the cottagers' division; first, second, and third being given in all. Special prizes are numerous, no less than forty additional classes being thus provided for. Some of the chief donors are the following:—The Duke of Teck, Lady John Chichester, Sir Arthur J. Rugge-Preece, Bart., the Dowager Lady Pigott, Sir Francis Burdett, the Duke of Buccleuch and Queensberry, Sir Trevor Lawrence, Bart., Lady Parker; and Messrs. Sutton & Sons, Osborn & Sons, Daniels Brothers, G. Paul & Sons, Hooper & Co.,

F. R. Kinghorn, and H. Herbst. The summer Show will be held on June the 30th, and the autumn Show in November. We are informed that the Croydon Horticultural Society will hold their Summer Show on Wednesday, the 29th of June, and the Autumn Show on the 14th and 15th of November. The prizes and classes are of the customary satisfactory character. The Finsbury Park Chrysanthemum Society will hold an Exhibition in the Holloway Hall on November the 16th and 17th. Mr. E. Makepeace, the Hon. Secretary of the Hampton Cottage Garden Society, informs us that the annual Exhibition will be held in the grounds of Garriek Villa, Hampton, on July the 12th of the present year. The fifth annual Exhibition of the Rochester and Chatham Horticultural Society will be held in the Paddock, St. Margaret's, Rochester, on Tuesday, July the 5th, when prizes will be offered in 120 classes for plants, cut flowers, fruit, and vegetables. We learn from the schedule that the Harborne and District Potato Exhibition will take place on the 16th and 17th of September in the Masonic Hall, Harborne. Twenty-four classes are enumerated, one for two best dishes of cooked Potatoes being noteworthy. The prizes in six of the classes are offered by nurserymen and seedsmen. We are informed that the International Potato Exhibition will be held at the Crystal Palace, Sydenham, September 20th and 21st. The Lord Mayor is President of the Committee, and the list of Vice-Presidents will probably not differ from that of last year.

In connection with the Essex Agricultural Society's meeting on June 15th and 16th of the present year it has been decided to hold a horticultural Exhibition at Southend-on-Sea, when prizes to the value of £130 will be offered in ninety classes, all the chief garden products being well provided for.

On Wednesday July the 6th the Norwood Horticultural Society will hold their fourth annual Exhibition. In addition to the usual prizes numerous special classes are contributed to by metropolitan firms of nurserymen and seedsmen.

The Burton-upon-Trent Floral and Horticultural Society will hold the annual Exhibition on Wednesday, June 22nd. The schedule enumerates a large number of classes for plants, flowers, fruit, and vegetables, some of the prizes being very liberal, especially for stove and greenhouse plants. In the chief class for twelve specimens £20, £10, and £5 are offered as first, second, and third prizes. The Birmingham Botanical and Horticultural Society will hold an Exhibition in their gardens at Edgbaston on Friday and Saturday, August the 12th and 13th. There is good provision for plants, flowers, and fruit. The Cardiff Rose Society announce July the 6th as the date fixed for their Show. In addition to the ordinary classes a number of special prizes are contributed by gentlemen and nurserymen in the neighbourhood. The Northamptonshire Chrysanthemum Society's tenth Exhibition will be held in the Corn Exchange, Northampton, on November 22nd and 23rd. The schedule shows the usual liberal arrangements for Chrysanthemums, with additional classes for miscellaneous plants, fruits, and vegetables.

We must also mention that the Committee of the Leeds Show have made a most worthy attempt to retrieve their lost fortunes, and it is to be hoped that the weather will smile on them this year and success follow. The Show opens on June 29th and continues for three days. The schedule is an excellent one, and the prizes numerous and liberal.

The Liverpool Horticultural Association will hold the third annual Exhibition in Sefton Park on July the 30th and August the 1st. Liberal prizes are offered in eighty-six classes for plants, cut flowers, fruit, and vegetables. Stove and greenhouse plants are particularly well provided for, the prizes ranging in the three chief classes from £12 to £2.

#### KITCHEN GARDEN.

Sow the main crop of Dwarf Kidney or French Beans, Negro Long-podded, and Canadian Wonder, placing the seeds about 2 inches deep and 6 inches asunder in rows 2 feet 6 inches apart. Sow also Scarlet Runners in rows 6 feet apart where long sticks are used, a less distance where the sticks are shorter, stopping the plants when they reach the top, and where sticks are not obtainable the rows may be 3 feet apart. Plenty of moisture and a warm

position are essential for the success of Runner Beans. If the soil be light draw it about 3 inches high and 18 inches wide on each side of the rows of plants, and mulching with partially decayed manure. Utilise the space between the rows of Peas for Spinach, Lettuces, and Radishes. Lettuce seed for a summer crop is best sown where the plants are to remain, thinning the seedlings to a foot distance apart. For late Peas in light shallow soils trenches should be prepared as for Celery, with the difference that the soil taken out is to be returned and the seeds sown on the level over the enriched trench. Examine Cauliflower plants, applying some rich soil to those wintered under handlights, watering as necessary with liquid manure, and make a sowing of Walcheren for late September use. Sowing Broccoli for late use should not be delayed; such varieties as Lauder's Goshen, Wilcove Improved, and Model, planted on a north border and laid-in in early winter, will afford a succession to those in the open, and possibly continue the supply until Cauliflowers under the handlights come in. Sow Savoys of the dwarf varieties Early Ulm, Tom Thumb, and Dwarf Vienna, which occupy but little room, and come into use early in autumn, being more esteemed than the larger varieties. Encourage growth in the several crops by hoeing frequently between the rows, which will save much after trouble with weeds. Make a successional sowing of Turnips on a north border. If dry weather ensue Turnip fly may be troublesome, but dusting the plants early in the morning with quicklime will check it. As ground becomes cleared of Broccoli and other crops it should be prepared for Celery, the early plants being placed out by the second or third week in the month. The space between the trenches will be available for a single row of Lettuces, which if well attended to will afford fine heads during summer. Hoe between the rows of early Potatoes, and draw a little soil round or over them if there is danger from frost. Spruce branches in readiness to place over them in the evening when frost is expected may save the haulm. Where Potatoes have been planted wide the ground between the rows should be forked, so that when the Potatoes are carted up it may be in a fit condition for planting.

In the forcing department Tomatoes fruiting in pots should have all laterals removed, and if the fruit is near maturity some of the plants may be removed to a cooler house so as to afford a succession. Shift into 5 or 6-inch pots those which are to be planted against walls outside, affording no more heat than is necessary to keep the plants growing. Ridges may now be prepared for Vegetable Marrows, Ridge and Gherkin Cucumber plants, which can be placed out as soon as they have been hardened. French Beans should still be sown in pits or frames for a last crop, affording copious supplies of liquid manure to those advanced. Carrots should have liberal supplies of water.

#### FRUIT HOUSES.

*Vines.*—Early Grapes now ripe will require very little fire heat, the temperature being allowed to fall to 60° at night. Where the fermenting material on outside borders has become cold a portion may be removed, leaving sufficient for a mulching. Increase the ventilation, especially in the early part of the day, and close early. Continue former instructions as to thinning, disbudding, stopping and tying. Examine the inside borders of succession houses at least once weekly, and afford supplies whenever necessary, alternating with liquid manure, both tepid. Late kinds now growing rapidly may be tied out and stopped as soon as they have covered the trellis with good foliage. Vines in pots for next year's fruiting will now be ready for transferring into 14-inch pots. Employ turfy loam with a sprinkling of bones and pot firmly. Newly planted Vines should be closely watched, not allowing the soil to become dry, and in training let all the shoots remain that can be exposed to light, but supernumeraries for next year's fruiting should be closely pinched and confined to one rod.

*Cherry House.*—Directly the stoning is complete the fruit will commence colouring, when, if it be desirable, the ripening may be accelerated by the maintenance of a higher temperature in the daytime. Ventilation must be attended to as before advised. To secure fine fruit more time should be allowed. When colouring commences cease syringing the trees, or the Cherries will crack. Keep the surface

of the borders moist, attending to stopping and tying in the shoots. Supply weak liquid manure liberally to trees in pots.

*Figs.*—With the early crop of these from trees in pots, the main object will be the ripening and colouring of the fruit; therefore allow a little ventilation at the top of the house constantly until the crop is perfected. Cease syringing the trees, and do not allow a superabundance of moisture about the house. Early forced trees in permanent borders will be advanced for ripening, and will require similar treatment, and if the borders have been attended to in watering and mulching they will not usually require further supplies until the crop is ripe. For home use we do not gather the fruit before it is perfectly ripe, but if it has to be sent a distance it should be gathered a few days earlier. Attend to stopping, thinning, and regulating the growths as before advised. Very early crops of Figs from trees in pots will shortly be exhausted, when the syringing may be recommenced twice daily; and if the second crop is abundant remove a part so as not to overtax the trees, especially if they are needed early next season.

*Melons.*—Directly indications of ripening appear a dry condition of the atmosphere must be maintained and less supplies of water given, but not so as to affect the foliage, particularly if a second crop is to be taken from the same plants. Afford support to fruit becoming heavy. Afford copious supplies of water to the roots of those plants with fruit swelling off, also giving weak tepid liquid manure occasionally. Syringe the foliage and walls at about 3.30 P.M., and damp the floors several times a day when the sun is powerful. Attend carefully to ventilating, particularly in the early part of the day. Maintain a temperature of 80° to 85° through the day, and close early in the afternoon, as it will not raise the temperature much over 90°. Pot off seedlings, keep them near the glass to insure sturdy growth, training and regulating the growths of young plants. After the fruit is swelling in pits and frames earth-up the plants, keep the laterals well thinned-out and stopped, and raise the fruit on slates on inverted flower pots. Maintain a good bottom heat by linings, and employ covering at night over the lights for some time longer.

*Cucumbers.*—Little fire heat will be required by day; the valves should be turned off about 8 A.M. and turned on about 5 P.M. In dull weather and cold days fire heat by day will be necessary. The supply of air and moisture will need to be increased according to the increase of light and heat. Houses facing due south will require shading at mid-day, regulating it according to the intensity of the sun. The night temperature should not be allowed to fall much below 70°, and 75° secured by day, and 80° to 85° from sun heat. Syringe the foliage at about 3.30 P.M., and damp the floors, &c., frequently through the day in bright weather. Afford liquid manure about twice a week. The importance of clean growth cannot be over-estimated; and instead of trying to clear the foliage of red spider, remove infested leaves and coat the hot-water pipes thinly with sulphur. Fumigate at once upon the appearance of aphides. In pits and frames, if the plants are healthy, shading will not be required at present, but the foliage must not be allowed to flag. Sprinkle the plants about 3 P.M., closing the lights at the same time, the temperature not being allowed to exceed 90°. Attend to stopping, training, and earthing-up, also sowing as necessary for succession.

#### ORCHARD HOUSE.

The wintry weather in early April has considerably retarded the progress of the fruit trees in this structure. Aphides often appear whilst the trees are in blossom, and in that case fumigation must be resorted to; but if it can be delayed without the serious spread of the insects until the fruit is set it will be safer. After the fruit is set syringe the trees well every morning when the weather is mild and not likely to be dull. Ventilation must be carefully attended to, opening the ventilators about 7 or 8 A.M., closing about 6 P.M.; or whenever frost or a low night temperature is expected close somewhat earlier, as no danger need be apprehended from a rather high temperature during the latter part of the afternoon. Apricots set and abundant should be thinned moderately, and any strong or superfluous shoots be rubbed off or pinched back to preserve the symmetry of the trees. If mildew appears on Peach and Nectarine trees dust them with sulphur. Fig trees are growing, and must be

abundantly supplied with water, for if allowed to become too dry a check will be given, causing the fruit to drop.

#### PLANT HOUSES.

*Orchids.*—For about four months forward most of the plants will be growing. Increase the temperature in the East Indian house to from 70° to 90° by day and 65° to 70° at night; Cattleya house 65° to 75° by day and 60° to 65° by night, and in the Odontoglossum house to 55° at night and 60° to 70° by day. Shading will be required as the season advances; and as air will be required at the same time the shading material must be kept from closing the openings for ventilation by having laths fixed to the roof, so as to allow a space of about 3 inches between the shading material and the glass. *Aerides*, *Phalænopses*, *Saccolabiums*, and *Vandas* must be constantly moist, and their foliage cleaned by frequent spongings. *Cymbidiums* requiring repotting should be placed in rough peat with small lumps of charcoal, giving good drainage, as plentiful supplies of water are required. Examine *Stanhopeas* frequently, and if at all dry soak them in tepid water, and any that are starting into growth should have the moss renewed. Very little if any fire heat will be required for the cool Orchids for the next four months, the difficulty in hot weather being to keep them cool enough. Some *Odontoglossums*, such as *O. citrosimum*, *O. hastilabium*, and *O. naevium*, require a little more heat than others, and should be placed at the warmer end of the house. *Lycastes* require similar treatment, but *Masdevallias* should be given the coolest part. Orchids required for conservatory decoration or exhibition should be gradually prepared for the change, placing them in a house with a north aspect and a temperature of 50°, water being gradually withheld so that the sphagnum is just moist.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

##### TREATMENT OF BEDDING PLANTS.

MANY of the hardier bedding plants may now be permanently planted out. This will give them a good start—those especially which have to be freely divided before hot dry weather is experienced, and will also admit of the glass employed during the winter for their protection being utilised for hardening off other more tender kinds. *Echeveria secunda glauca* is most effective when disposed in the margins of raised beds. They should be placed to face outwards, and the ordinary soil, if made tolerably firm, will keep them in position without clay. If scarce they may be disposed thinly with either *Sedum glaucum* or *Mentha Pulegium gibraltarica* interspersed. An inner line of *Golden Pyrethrum* contrasts well with the *Echeverias*, and the beds can then be filled with either the ordinary bedding plants or carpeting plants. The *Pyrethrum* is particularly suited for marking the lines in carpet beds, and if large enough may be dibbled in at once, choosing a dull day for the operation. They should be put in thickly, say about 2 inches apart, the aim being to secure a fine line rather than large plants. What is technically termed the "groundwork," in other words the spaces between the figures of the design, is usually filled with close-growing plants, such as the *Mentha*, *Sedums*, *Herniaria glabra*, and occasionally *Mesembryanthemum cordifolium variegatum*. All with the exception of the latter may be divided into very small pieces, this in preference to large patches, and be dibbled in so they touch each other. The soil should be very fine and rather light, level, and firm, or otherwise the effect will be marred. To avoid undue trampling during the operation of filling the beds work upon planks, blocking these up clear from the soil. The brighter-coloured tender plants to be filled in early in June.

Autumn-struck bedding *Pelargoniums* that are well established in either pots or boxes may, if frames are unavailable, be placed on ashes in a warm sheltered position, and covered during frosty or cold wet weather with mats or other protecting material, supported by a temporarily erected framework. They should be watered rather sparingly when first turned out. *Pelargoniums* are best potted off singly into 3-inch pots, and should have the preference, as such kinds as *Lobelias*, *Pyrethrums*, *Verbenas*, *Ageratums*, *Heliotropes*, *Petunias*, *Iresines*, and *Alternantheras* not only grow more freely in boxes, but can also be transplanted readily from them. Avoid using deep boxes, especially for the two last named. These and *Coleus Verschaffelti*

may be propagated till the end of May, and very frequently these late-struck plants start into growth more freely than do others which may have been in cold frames for some time previous to being planted. *Mesembryanthemums* should be potted-off singly into small 60's; but as these, *Coleus*, *Iresines*, and *Alternantheras* are the last to be planted, the pots previously filled with the *Pelargoniums* may be utilised for many of these, as the plants will quickly become established if placed in a gentle heat after being potted.

The dwarf bedding *Tropæolums* of the Tom Thumb section must also be potted off singly in 3-inch or smaller pots, and the same size or larger for the variegated *Maize*. The bedding *Amaranthuses* are very tender, but in heat are quick-growing, and therefore if sown now may be eventually potted off singly and be ready for planting early in June. *A. melancholicus ruber* is a good substitute for *Iresine Herbstii*, and *A. Henderii* includes some very pretty varieties suitable for the subtropical garden. Seedling *Cannas* may be potted off, and old roots that have started can easily be separated, potting the divisions; or if the clumps are strong defer dividing till planting time. Similar remarks apply to *Dahlias*. *Ricinus* seeds germinate quickly, and if sown in gentle heat at the present time, and the young plants are potted off singly into 5-inch or 6-inch pots, they are soon fit for planting. Early sowing and early planting are injurious to *Ricinus*. *Eucalyptus globulus* and *Acacia lophantha* should be potted into small 60's, grown on in heat, and shifted into 5-inch or 6-inch pots before becoming root-bound. The ornamental-foliaged *Solanums* may be treated similarly. Stocks, Asters, Marigolds, Zinnias, Godetias, *Helichrysums*, *Dianthus*, *Phloxes*, and other annuals may either be pricked out in boxes or in a bed previously occupied with early Potatoes. To be successful with these prick them out before they become crowded, and plant them out when of good size. Many plants are injured by being raised early and afterwards kept in boxes till perhaps the flowers of some kinds are forming.

#### HOW, WHEN, AND WHERE TO USE COMB FOUNDATION.

(Continued from page 344.)

THE fixing in the frames will next require attention, and if this be done with molten wax a most perfect tool can be easily made, and as follows: Cut a board (at least half an inch thick) slightly less in length and width than the inside measures of your frames, and across the back of it fix two battens cut so long that they project half an inch top and bottom. If this board be laid down the frame may be slipped over it, when the back of the frame will rest on the batten ends. If the sheet of foundation be now placed upon the board it will be found not to stand exactly in the middle of the width of the frame. To regulate this put four small screws into the projecting portions of the battens, and turn them down until the sheet standing on the board is in accurate position with regard to the frame which is now resting on the screw heads.

The foundation, either in sheets half an inch less each way than the frame, inside measure, or in strips for guides only, is brought against the top bar when the board is held in the hand with the top bar of the frame downwards and inclined to the horizon. If now a few drops of molten wax are allowed to fall at the upper end and at the point where the sheet meets the top bar, the wax will run, and, almost immediately setting, our foundation will be securely fixed in accurate position. To prevent cracking a little care is needed. The board is brought to the perpendicular; and now, but not till now, the frame may be removed and hung in a spare hive until required. Wax should not, in my judgment, be used on both sides. One side is sufficient, and no breakdown can ever occur if care be taken and the wax used hot enough. Waxing on both sides leads sometimes to disaster, because the form of the foundation is in part obliterated as the wax runs over it, and hence the bees do not there so quickly build out the cell walls. From this cause the comb is occasionally left thin at top on both sides, and if heavily stored below is apt to break away. It is desirable to damp the board to prevent the wax which may reach it from adhering. A glue-pot may be used for melting the wax, and a spoon is passably convenient for applying it, but those possessing many hives would do well to purchase a little article called a

"Smelter," which can be had of the dealers. It is like a glue-pot in principle, but a small spout is provided from which the wax can be poured with accuracy.

In May last year I explained so fully my method of fixing foundation with wires, which I named "Cheshire's Foundation Fixers," that I would rather refer to the articles then appearing in the Journal than go over the ground again. Suffice it now to say that wires are provided with half an inch turned up at right angles at each end, so that they pass just over the top and bottom bars of the frame as it lies around the board previously described; upon each wire five pins are soldered by their heads at equal distances, and are then cut down in length to a little more than half the width of the frame. It will be seen that if the sheet be placed upon the board and one of the pinned wires be passed over the frame, the turned ends will hold the wire to the frame, while the five pins piercing the foundation will fix the foundation to the wire. If five or six of these be used the whole sheet is held most securely. As thirty distinct immoveable points of support are given sagging or stretching is impossible, while perfect flatness is secured. Nor is hot wax needed, as the bees quickly fix the top edge, and for a reason just explained the chance of the comb being left thin above is removed. The wires had better be taken away as soon as the combs are sufficiently drawn out to make sagging unlikely. Swarms may by this means have full sheets given them throughout the hive, while pieces of foundation may be patched together and converted into good combs, so regular and perfect as to excite the astonishment if not the envy of those in their novitiate. Seeing a thing is often of great service, and so I here repeat my willingness to show these matters in progress to those who may be really sufficiently interested to call to examine them.

Our foundation is now waiting to be introduced; the wind has turned into a warm quarter, and we open a stock to ascertain its condition. We note it has plenty of bees and two combs of fully sealed store at the end; we remove one of these, and upon examining the frames find the queen is being a little troubled to discover cells enough for her eggs; room is now made in the brood nest, and the sheet of foundation is inserted; in twenty-four hours it is built out sufficiently to have given the queen some accommodation, for eggs are seen in the middle of it. The fixers are removed, we intending next day or the day after to repeat the process. We now visit a hive thought to be a little behind; we find it poor, with but three frames of brood. To insert a sheet of foundation in the centre here would perhaps involve chilled brood if the weather took a bad turn, and everybody admits that in Great Britain it is a little uncertain; we therefore shave the comb taken from the hive first examined and put it beside the brood nest. The honey will be removed, and everything set briskly going, a comb thus shaved constitutes a fine stimulator for a poor and weak stock. When combs are built on foundation, properly managed, the midrib is always in the right place, so that any irregularity that the bees may cause by extending the length of the cells when storing, may be got rid of perfectly by thus simply slicing down with the knife. A third stock shows unmistakable signs of requiring more room; it is highly prosperous. We give it foundation in the centre of the nest. Near by a stock stands which lost its queen in some way a little time since. It is about hatching a queen from brood given, but the time is yet young, and the mother-expectant may be lost in mating, when the stock would be ruined. Giving it a comb of eggs from the prosperous colony will keep the bees going, and by-and-by sustain its strength, while the loss to the well-to-do will be quite inconsiderable, as into the space opened we slip a sheet of foundation, which in two or three days will be a comb as fully furnished as the one removed. In giving foundation at this part of the season it is far best to place it, if the stock can bear it, so that it will be worked rapidly, and both sides at once. If this is neglected a curling of the sheet from the side first drawn out may take place, because of the expansion of surface this drawing-out occasions. Should other circumstances permit, it is good to place foundation between the straightest combs the hive possesses, but really now there is little need for any combs to be far from perfect in this direction. That space forbids my continuing this subject further is unimportant, as the points here omitted will occur naturally in the calendar for May in next issue.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

#### OUR INDIAN BEES, ESPECIALLY APIS DORSATA.

(Continued from page 321, and communicated by Alfred Neighbour.)

As the readers of our Journal are aware, Mr. Frank Benton, Professor of the State College of Agriculture of Lansing, Michigan, U.S. of North America, has started from the island of Cyprus on a visit to the islands and continent of the East Indies in quest

of *Apis dorsata*—that large bee with which we are most anxious to become acquainted—and of other valuable species of bees, which in case of success he intends to introduce and acclimatise first in Cyprus and to export thence to America and Europe. No doubt all bee-keepers are anxiously waiting to hear how Mr. Benton progresses, and having received a letter on this subject to-day I hasten to publish the contents for the benefit of the readers of the *Bienenzeitung*. Mr. Benton's letter to me is written in German, and reads as follows:—

"Singapore, 8th February, 1881.

"DEAR SIR.—I sailed from the island of Cyprus on the 4th December last, taking with me some colonies of Cyprian bees. I remained in Palestine for a short time, and took some colonies of Palestine bees with me when I left there. On my arrival in Ceylon I found to my great surprise that they do not keep bees on that island—not even in the primitive way in which on the island of Cyprus people keep the native bees in pots or clay pipes. I at once wrote an article, and sent it to the principal journal published in Ceylon, expressing my surprise that bee-keeping was still unknown in this fertile and suitable island. I mentioned how many colonies of bees there are on the island of Cyprus—31,432 in 1879, which figures I have taken from the books of the collectors of taxes there; but the actual number of hives on the island at that time was doubtless much greater. In former years there were 200,000 stocks of bees in the small, poor, and parched island of Cyprus! I also stated how large a profit the Cypriots derive from bee-keeping, and indicated the best way of commencing bee-keeping in Ceylon, advising a beginning to be made with the native species. A few wealthy and influential gentlemen who showed an interest in the introduction of bee-keeping in Ceylon, and still more in procuring some colonies of *Apis mellifica*, consequently called upon me. I am glad to be able to say that owing to my endeavours bee-keeping has become a fact in Ceylon. I have placed in good hands there a few colonies which had accompanied me from the island of Cyprus.

"There are four species of honey bees in Ceylon, which in the language of the natives are named as follows:—1, Kana Mee meso; 2, Dandual Meso; 3, Mee Meso; 4, Bambera. The Kana Mee meso is doubtless a species of *Trigona*, and is very small; it has no sting, and always builds in hollow trees, collecting honey and pollen, but it is of no value to bee-keepers. I took a nest, together with the bees and queen, of this species from a small hollow tree in the jungle, which I have brought away with me. The second species, Dandual Meso, I did not meet with, but I secured a piece of comb of these bees. The cells are regular hexagonals, made of wax, a square inch containing eighty-one cells; the comb is five-eighths of an inch in thickness. I have been told that these bees generally build their combs in the open air, always placing them perpendicularly, and storing honey in them.\*

"Combs of several colonies of the third species, Mee meso, which is doubtless the *Apis Indica*, were obtained from the rocks and hollow trees in the primeval forests on the island, and these, together with the queens and worker bees, were placed into wooden frame-hives of my own construction. The worker bees are three-eighths of an inch long, of beautiful yellow colour, and are very swift on the wing. The chief characteristics of these bees are their gentleness, prolificness, and great industry. Thirty-six of their worker cells cover a square inch. Their drone cells are exactly like the worker cells of our yellow bee *Apis mellifica*, and might very well be used by our bees for breeding workers. This species is undoubtedly suitable for breeding.†

"On the island of Cyprus honey is obtained from this bee as well as from the Bambera, the fourth species, and the largest bee of the island.

"This large bee, Bambera, is found in the interior of the island, and is but rarely seen near the seacoast. When I learnt this I had not time enough to pay a visit to the interior of the island, being obliged to start for the island of Java. Although I did not obtain a sight of this bee I procured some information concerning it from most reliable sources, and I have no doubt of this bee being the famous *Apis dorsata*.‡

"According to this information this bee sometimes certainly builds its combs in the open air, not, however, horizontally, but always perpendicularly. To correct a mistake which has got abroad about *Apis dorsata*, I may mention that there are many hornets in Ceylon, which of course invariably make their combs horizontally, these hornets, in the language of the inhabitants of Ceylon, being called Debora. The people of Ceylon speak the Cinghalese language, which

\* This comb evidently comes from *Apis florea*, which is the smallest of all Indian bees. Their worker-cells are likewise hexagonal, the drone-cells have much thicker walls and their interior is almost cylindrical. Thirty-three and two-thirds worker-cells of *Apis florea* are equal in length to 18½ worker-cells of our own bee.—THE EDITORS.

† Mr. Benton was doubtless correct in taking Mee meso to be *Apis Indica*. The latter has also been described as *Apis socialis* (Lepelletier), *Apis Delesserti* (Guérin), *Apis Peronii* (Latreille), *Apis Perrottetii* (Guérin), and *Apis nigrocincta* (Smith).—THE EDITORS.

‡ Mr. Benton is quite correct. The Bambera—Bamburos—is *Apis dorsata*, the races and varieties of which have been described as *Apis nigripennis* (Latreille), *Apis bicolor* (Klug), and *Apis zonata* (Guérin and Smith).—THE EDITORS.

is derived from the old Sanscrit, in which language the word Debora signifies a bee. But the name of Debora is at the present day applied to the hornet in Ceylon, and this may probably have given rise to the erroneous statement which has reached Europe from Ceylon about *Apis dorsata* building its combs horizontally. A scientific gentleman in the Civil Service of the English Government of Ceylon assured me that he had measured a comb of the *Bambura* in the primeval forest near Adam's Peak, and found it to be more than 6 feet in length. This comb contained so much honey that the branch of the tree to which it was attached had actually broken from the weight of it. Another highly respectable gentleman assured me that he had seen thirty people laden with honey and wax just as they were about to leave near a hollow tree in which the *Bambura* had settled, all this honey and wax having been taken from that one tree. I saw a comb of this species in the museum on the island of Ceylon; it was  $3\frac{1}{2}$  feet long by 2 feet wide, and  $1\frac{1}{4}$  inch thick. It had only been used for rearing worker bees, but where the honey had been stored it was about 4 inches thick.

"I have tasted the honey collected by *Apis dorsata*, and if it had not been pointed out to me as such I should certainly have taken it for honey from our yellow bee, *Apis mellifica*."

"I quite believe *Apis dorsata* to be suitable for breeding. We must not be prejudiced against these bees because they build their combs in the open air. Our yellow bee does the same thing in tropical countries, and when unable to find a suitable place to settle."

"I hope to be back in Cyprus in the month of April in order to continue breeding Cyprian bees during the present year, and to despatch queens of these bees to Europe."

"Your Sincere Friend,

"(Signed) FRANK BENTON."

The above is the account of my esteemed friend concerning his endeavours to hunt up *Apis dorsata* in its native country, in order to acclimatise these bees in Cyprus and America. As soon as I receive further news I will not fail to make it known through the columns of this paper.

In conclusion I may remark that this article has, in addition to the *Bienenzeitung*, been communicated to editors of other journals with whom I am on friendly terms.

Brux, 8th March, 1881.

(Signed) EDUARD CORI.

\* Our native black bee if unable to find a suitable habitation when swarming sometimes builds in the open air. A case of this kind, though of rare occurrence, happened a few years ago on the Bavarian frontier at a distance of an hour's ride from the town of Eger, where a swarm of bees had made combs in the branches of a young Fir tree. I have been informed of this occurrence by bee-keepers of Eger.—THE WRITER OF THE ABOVE ARTICLE.

#### TRADE CATALOGUES RECEIVED.

Bruant, Poitiers, Vienne, France.—*Catalogue of Plants.*

John Halliday, Bridge of Allan.—*Catalogue of Gladioli, Roses, Pansies, &c.*

\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Hardiness of Roses** (*A Subscriber*).—All the Roses you name, grown as dwarfs and protected with manure in the autumn, will survive all ordinary winters except in unusually cold districts. In mild winters they would succeed as standards.

**Exhibiting Dahlias and Pansies** (*Cottage Gardener*).—Some societies state the sizes of the boxes in which the flowers must be shown. A box 7 inches high at the back, 5 inches in front, and 18 inches wide would be suitable for three rows of Dahlias, the length being determined by the number of blooms to be exhibited, allowing 6 inches for each bloom. The larger the blooms are, provided they are firm, symmetrical, and bright and clear in colour, the better; but large blooms, if coarse, would be passed by the judges. The holes in the boxes for Pansies should be  $2\frac{1}{2}$  inches apart. You will find the properties of flowers in our "Florists' Flowers" Manual, which you can have in return for  $4\frac{1}{2}$ d. in postage stamps.

**Recommending Nurserymen** (*Captain, R.N.*).—As we have many times stated, it is quite impossible that we can recommend any particular nurseryman; it would be most invidious and unfair for us to do so, as it would

be a tacit condemnation of others who deserve no such mark of disapproval. You are much too late in seeking what you require, and you can scarcely expect to be served in a satisfactory manner with what you want until the autumn, when you will have no difficulty whatever in procuring what you require.

**Stopping Peach Trees** (*A. C.*).—As you do not desire to increase the size of the trees all the shoots may be pinched at the third leaf, the three leaves being large, not counting small imperfect leaves that often form at the base of the shoot. The shoots following must be pinched at the first leaf, continuing the practice as long as necessary. If the trees are much crowded with growths a portion of them may be removed entirely, as if the spurs are very numerous the foliage is too much crowded for the production of fruit buds. When the pinching is properly done and the trees are in other respects well managed Peaches bear as well on spurs as on young wood, the fruit buds in both cases being formed during the current year.

**Syringa not Flowering** (*N. S. R.*).—The severe pruning to which you allude is the cause of the shrub not flowering. The growths produced after the pruning would be luxuriant, and if these were again cut down similar results must follow. If you cease pruning, or only prune very slightly and judiciously, obtaining smaller shoots than can be matured by full exposure to the sun, thinning out superfluous growths if needed to prevent overcrowding, your shrub will again flower. When a *Syringa* is well formed and in flowering condition it will continue so, if it is not pruned beyond the removal of any branch or shoot that is out of place and mars the appearance of the specimen. If your shrub had not been pruned at all it would have continued flowering.

**Removing Conifers** (*R. W. B.*).—Very much depends on the nature of the soil in the successful removal of Conifers. In some soils they produce an abundance of fibrous roots, to which the earth adheres with considerable tenacity; in other ground the roots are fewer and less fibrous, and the soil falls from them when moved. If you will adopt a safe plan by digging round the specimens now quite below the roots, and if you can place soil containing much vegetable matter, such as decayed leaves and similar refuse, in the trenches, pressing it firmly, you will encourage the production of fibres, which will be of great value when the specimens are transplanted. The distance of the trenches from the stem must depend entirely on the size of the trees, and especially of their diameter at the base, which you do not name. The whole work must be done with thought and care.

**Growing Flowers for Perfumery** (*J. E., New York*).—Since you have no practical knowledge of this subject, and as we are unable to supply the information you need, the best advice we can give you is to write to Messrs. Piesse & Lubin, perfumers, Bond Street, London, and they will send you particulars of a work which they publish, and which will be of service to you; they may perhaps also be able to give you other instruction on the subject such as you appear to require.

**Raising Seeds of Indiarubber Plants** (*San Juan*).—Prepare some pots or pans by draining them thoroughly with potsherds, on which should be placed a little rough soil or moss, then filling up with finely sifted soil and sand in equal parts. Sow the seeds, and cover them with about half an inch depth of similar soil, plunging the pots in a hotbed or propagating frame, being careful that too much water is not given, and also that the soil is not allowed to become dry. If the seeds have been thoroughly ripened they may germinate in the course of a month or a little more. The implement you mention continues satisfactory and is not likely to get out of order.

**Horticultural Shows in June** (*Mrs. Webster*).—The following Exhibitions will be held in London during the period you name. The Royal Horticultural Society, South Kensington, Great Summer Show, June 3rd; Evening Fête, Rose and Pelargonium Show, June 28th. Royal Botanic Society, Regent's Park, Evening Fête, June 15th; Summer Show, June 22nd. Croydon, June 29th; and Richmond, June 30th. The National Rose Society's Show will be held at the Crystal Palace, July 2nd.

**Peach Flowers Dropping** (*M. D.*).—Peach trees cast their buds from a variety of causes, the most common perhaps being drought at the roots, not at the time when the blossoms ought to be expanded only, but many months previously. Overcrowding of the growths in summer, attacks of red spider, immaturity of the wood, and a close atmosphere, all contribute to the same result. It is impossible for us to say what has been the cause of the evil in your case on the data you have afforded us. A portion of the wood would have aided us in arriving at a decision; but in the meantime we advise you to examine the border 2 feet below the surface. Many borders have a moist appearance when the soil is dry below, and in such a case the flowers must fall.

**Fuchsias Diseased** (*A. A., Burn*).—We are not able to account for the condition of your Fuchsias on the data you have afforded. We perceive there have been insects on them, and we think thrips, which are very injurious, and when numerous cause results similar to those before us; but we do not think they have been in such great numbers as to injure the plants so seriously. We are intimately acquainted with a gardener who grew Fuchsias luxuriantly in one place, and in another no plants gave him so much trouble; the wood ripened prematurely, and the growths had a rusted appearance much like those you have sent. He tried various mixtures of soils, loam forming the base, but with unsatisfactory results. At length on close investigation the soil of the field from which the loam was taken was much impregnated with iron. Loam was then obtained from another source, and the plants then grew satisfactorily. Cut off all the diseased portions, and try some soil from another district.

**Pruning Dwarf Apple Trees** (*J. S., Cairnie*).—As you require the trees very dwarf you will not succeed in having fruitful specimens if they are not worked on a dwarf-growing and precocious stock. You had better prune them at once, the same as you would prune Red Currants—that is, by removing the side growths if any, and shorten the ends to the length desired in accordance with the form and symmetry of the trees. If the branches are numerous thin them out, and in summer pinch the side growths when they have formed four good leaves, allowing the ends to grow, at least until August. It is summer, not winter, pruning that induces fruitfulness and restricts the luxuriant growth of trees. Details of pruning the various kinds of Roses have been frequently given. No one can answer your question without knowing the kind of Roses to which you refer and their condition. You can only check the roots of the Ash trees by constantly cutting them, at least if you require crops of some kind to grow on the site that has been trenched. Your objects, and the conditions of the cases you have submitted, are not sufficiently explained to enable us to reply to your questions satisfactorily.

**Flies on Peach and Nectarine** (*B.*).—The pale insect with large gauzy wings is a lacewinged fly (*Hemerobius perla*), of utility because the grub feeds upon aphides. The dark stout-bodied fly is *Leptis scolopacea*, a species not unfrequent in gardens; its grub feeds upon decayed roots. Neither of these can have anything to do with the injury sustained by the leaves, and on

examination it appears that they have been devoured by the caterpillar of some moth. This has probably kept itself concealed during the day, perhaps under the earth. It is curious how, whether making holes in the leaves or incisions at the edges, the caterpillar has avoided the ribs. There can be no remedy except searching carefully for it, and removing leaves that have been so far bitten as to have their vitality impaired.

**Vines Dying** (*H. E., Crouch End*).—In the first place we have to inform you that your Vines, even when alive, were in a very weak and unsatisfactory state. The growth has been weak and the wood not matured last year. It is a disappointment to you, no doubt, that the rods have died; but you have not sustained any great loss, for canes so badly grown, either through unsuitable soil or unskilled attention, could never have produced satisfactory crops of fruit. So long as the roots and the lower parts of the Vines are healthy, the occurrence which you regret may prove of advantage rather than otherwise, as you may hope to encourage the growth of young canes that will be far better than the old rods; in fact, if such Vines were ours, and alive, we should cut them down with the object of obtaining more healthy and fruitful wood. We attribute the cause of death to the dressing you have applied coupled with the weak condition of the Vines, and it is a matter of chance that all of them were not killed. You have used the soft-soap mixture at least four times stronger than you ought to have done. The maximum strength recommended for dressing Vines in winter is 8 ozs. dissolved in a gallon of water, while you have used 1 lb. of the soap to half a gallon. Of this strength the powerful caustic properties of the potash, which is a large ingredient in the soap, could not fail to injure the bark and arrest the flow of sap. The tobacco water was also too strong by half. Half a gallon of boiling water poured on 2 ozs. of strong tobacco would have produced liquor quite strong enough. In future do not exceed this strength, nor 3 ozs. of soft soap to the same quantity of water. The other ingredients may remain as before, as they will not do harm, nor, we think, much good. We have no difficulty in keeping our Vines clean without painting them with lime, sulphur, soot, clay, &c.; but some gardeners we know attach value to such a dressing, and so long as they produce fine Grapes we do not dissuade them from adopting the practice. Our verdict, then, is that you have accelerated the death of your Vines by a powerful dressing of soft soap—namely, a pound of soap to half a gallon of water.

**Onions for Pickling** (*Inquirer*).—We know of no better mode of culture for securing a plentiful supply of small, firm, round bulbs than that adopted by those market gardeners near London who grow Onions largely for the purpose in question. Their plan is to trench a piece of ground sufficiently deep that a thickness of 3 or 4 inches of the subsoil is placed on the surface. The seed is sown very thickly indeed, and on this account and the land being poor the plants grow weakly, producing thin necks, rush-like foliage, and very small bulbs. We have seen a ton of bulbs produced on a piece of ground, and scarcely one of them larger than a Cob Nut: thus grown, or starved, the bulbs mature early and are harvested during hot weather in summer. The crop is grown in an open and sunny position, and better results are obtained than by sowing under trees—a plan that is adopted with a fair amount of success in some gardens. The present is the time for sowing the seed of the small Silver-skinned variety. The ground prepared as above described is, when manured and turned over again, in splendid condition for almost any crops that require deep and good soil.

**Seedling Gloxinias and Cinerarias** (*Merrick*).—We never received flowers in worse condition than the Gloxinias you have sent. Inserting their stems in bits of Rhubarb stalks was of no use in preserving the freshness of the flowers, as the ends protruded through and were in contact with the dry cotton wool. This material, as we have before stated, extracts the moisture from flowers, and those that are packed in it invariably arrive in a withered state. Soft green Spinach or other leaves are much preferable for packing, damp moss being secured round the stems of the flowers. The flowers of your seedlings are of great size and substance, and the colours, so far as we can judge, are varied and good. We think the varieties possess considerable merit, and the plants have certainly been admirably cultivated. The double Cineraria is very fine, and much resembles Mr. Thomas Lloyd that was certificated last year.

**Insects on Strawberries** (*C. M.*).—These are the maggots of a crane fly, most probably *Tipula oleracea*; the species was very injurious during the spring of 1860. One of the more prominent points in Miss Ormerod's report on the injurious insects of 1880 has reference to the profusion with which *Tipula oleracea* appeared in many districts, attacking not only grasses and cereals, but also damaging crops of Cabbages and Peas in several places, and sometimes attacking Strawberries. A succession of experiments showed that this grub has astonishing powers of defying poisonous applications to the soil. It has been suggested to apply at night (when the maggots are stirring) carbolic acid much diluted, or the ammoniacal liquor from gasworks. A solution of hellebore might also be tried, as Mr. Witherspoon has said, "in soil saturated with hellebore no insect can live, and yet plants are not injured;" but he has not tried its effects on the phylloxera. It would be interesting to know if he has tried it on the maggot of the *Tipula*, and this pest, we believe, is often more difficult to kill than phylloxera. You might try the remedy yourself of the strength named on page 321, and if this does not have the desired effect increase the strength and oblige us with the results.

**Names of Plants** (*W. Muir*).—*Odontoglossum maculatum*. (*C. H.*).—*Omphalodes verna*. (*E. M.*).—The large white flower is *Magnolia conspicua*; the brown flower is *Fritillaria meleagris*; the double mauve flower is *Cardamine pratensis flore-pleno*; and the *Primula* was too small for identification, but resembles *P. intermedia*. All the numbers were displaced from the specimens, but the above will possibly be clear to you. (*W. H. W.*).—1, *Centradenia rosea*; 2, *Goldfussia isophylla*; 3, Unrecognisable without flowers; 4, *Rhynchospermum jasmoides*; 5, *Mikania pulverulenta*; 6, *Hibiscus Cooperi*. (*A Subscriber*).—1, *Berberis dulcis*; 2, *Cotoneaster microphylla*. (*G. O. S.*).—*Forstia viridissima*.

**Bees—Various** (*Buzz*).—1, Removing the stock immediately after the swarm has left will occasion the least loss. If many bees return to the old spot place a little brood in an empty hive on their old stand, and bring them home in the evening and add them to the swarm. 2, Propolis is gathered in autumn principally; if new cotton be used under the quilt it will cost little and save much inconvenience. Bees propolise most where there is bad fitting. If any ray of light can be discerned they make every effort to stop all crannies. 3, We have found *Arnica montana* more generally useful than anything else we have tried as a remedy for stings; it is almost always a specific. Put ten or twelve drops of the tincture into a wineglassful of water, and keep a linen pad soaked with the lotion upon the puncture. Where this has been done promptly we have never known of any discoloration of the eyes or any obstinate swelling. Dr. Pine's lotion is spoken well of by some, others have found it inoperative. *Ledum palustre* of the homoeopathic chemist, or *Urtica urens*, are both occasionally most serviceable. 4, Comb honey for food should be placed in the middle

after being uncapped if the stock is fairly strong. Read an article in this issue. The maker you mention supplies the form recommended. We could hardly publicly suggest a name. 5, If bees are now allowed to store and seal syrup the combs so sealed would not be admissible in the extractor. We are so arranging that the store is continually returned to the brood nest, so that in most of our stocks brood is found in every comb. Our very strongest stocks have so little honey that four or five days' bad weather would reduce them to extremities. We have not fed at all with syrup as yet, but if bad weather came on we should be compelled to do so immediately. 6, The less smoke the better, is our motto; but at the same time very irritable colonies cannot be handled in comfort without a good deal of it. With those that have a bad reputation it is wise to smoke moderately at the mouth one or two minutes before opening, and then more vigorously above as the quilt is being lifted. A veil should be worn in manipulating vicious bees in frame-hives. Is the smoker you use of good form? Bingham or the "cold draught" would give you an easy victory over hornets.

#### COVENT GARDEN MARKET.—MAY 4.

A VERY fair business doing during the week, Grapes of good quality reaching us in better supply, and being quickly cleared at lower prices. Strawberries a ready sale.

#### POULTRY AND PIGEON CHRONICLE.

#### AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 346.)

IN continuation of our observations upon the advantages and economy in construction of tillage implements and their convertibility for different operations we will take Howard's Champion plough as an illustration, although various other makers offer ploughs of somewhat similar advantages, notably Messrs. Ransome, Head, & Jefferies. We find that many of the best ploughs may be used, not only as ploughs under varying circumstances of soil and situation, but also be made the basis of fittings for numerous kinds of tillage work. We will notice first the plough frame being fitted with digging breasted turn-furrow, and subsoil tines attached for pulverising the soil in the act of turning the furrow; and this in some cases goes far towards saving afterwork in scari-fying, a matter of considerable economy on some land. On the removal of these fittings, however, we have a framework sufficiently powerful and substantial to allow of its being used for subsoiling purposes, with a subsoil frame instead of the ordinary plough body, and yet being as light of draught as can be obtained under the circumstances of severe strain upon the implement. The next metamorphosis which the plough may undergo is by fittings for Potato-raising with double lifting frame, which in use and drawn by a pair of horses will raise 3 or 4 acres of Potatoes in a day. It leaves fewer tubers in the ground, and they are

raised with less bruising and abrasion of the skins than by any other method. For carthing-up Potatoes also it will be found in some cases a better implement than the ordinary ridging plough, as it throws the earth more lightly on to the plants; nevertheless by removing the raising frame and putting on the ordinary double breasts and share it is at once converted into a ridging plough, which may be used for carthing-up or forming stretches for Mangold, Swedes, or Potatoes. These breasts are fitted to the plough in such a manner that they can be readily expanded or contracted, and this independently of each other; also by simply removing the breasts and attaching the hoes these implements can be used as horse hoes by having attached to the frame a cross-bar, and to which in using it as a ridging plough a rod may be joined as a marker in setting out the stretches.

We must not, however, overlook the turnover, the turn rest, or Brabant plough, in the construction of which the shares, coulter, &c., being rigidly attached to the plough renders the implement far more durable and efficient than those in which joints and moving parts are employed to effect the change from a right to a left-handed plough. The moving and turning are accomplished with remarkable ease. Now these, often called one-way ploughs, are especially adapted for work on hill sides where all the furrows are turned down hill, or for sewage, and wherever one-way ploughing is required.

We must now refer to scarifiers. The one so long in use, and to which we have when judge of implements often awarded the prize as the best scarifier, which was first invented by Mr. Coleman, is a powerful implement, and we think the only one which under horse power capable of moving the land in a season of severe drought. It, however, requires so much horse labour that we prefer now to use instead the paring or subsoil plough body, with a cutting share of the description used by Bentall in the scarifier bearing his name. By this means the land, however hard, may be more effectually moved than by any scarifier yet invented, after which it can be effectually tilled with Howard's self-lifting wheel harrows. These implements will be found very serviceable both as drag harrows and as light scarifiers. They possess an advantage over the ordinary drag harrow in being mounted on wheels, which whilst diminishing the draught allows of ready adjustment for harrowing or breaking up the land deep or shallow as may be required. When the implement arrives at the end of the field, upon the driver releasing the lever the harrow by the forward movement of the horses is at once clear of the ground by the draught chain attached to the arm of the lever. This arrangement is also convenient and useful for clearing the harrow of any accumulations of Couch or weeds without stopping the horses. The tines are fitted with moveable steel shares or points, which can readily be replaced when worn.

We will for the present conclude our remarks upon tillage implements by alluding to Howard's new patent steel chain harrow. The tripods are constructed of wrought steel rods instead of cast iron; and by an improvement in their form, the back part being at right angles, the harrow is rendered as efficient for arable land as the common chain harrow, while at the same time its superiority as a grass land harrow is maintained. When used upon arable land the harrow should be drawn the reverse way. This implement, according to our experience, is one of the greatest improvements in connection with the seeding of land with Clover, Grasses, and all small seeds, and also in following the drill after sowing Turnips, Mangold, Carrots, &c.

We will now refer to the improved corn and seed screens, one of the best of which is that made by Messrs. Coleman & Morton, constructed so that not only can the seeds of weeds, &c., be sifted from corn, but also other seeds, such as Clovers, be prepared for market. It has the further advantage of being set so as to divide

Barley from Oats where they have been grown together as drege. This latter object is a most important one, for upon certain soils it is very difficult to grow a plump malting sample of Barley by itself; it is, however, as a rule sure to produce an excellent sample when grown with Oats. It will therefore answer a good purpose to separate the grain, and this screen will do it effectually if the grain is properly prepared by the Barley Hummeller, designed for removing the awns or beard attached to the grain. After this has been properly done there is no difficulty in securing a good sample of first-class Barley, as the Oats and thin Barley grains pass through the screen, leaving only the plump grain behind as a malting sample.

A corn screen is offered by Josiah le Butt, which was formerly known as Roby's patent. This screen is so contrived that it can be attached to the finishing threshing machine, but the winnowing blast can be instantly dispensed with by simply removing the strap, when it becomes an ordinary screen. Nalder's Barley and malt screens are worth attention, for they are adapted for two purposes—preparing Barley for malting, and screening the dust from the malt afterwards. It is very evident that if the maltsters or brewers find it answer the purpose to purchase Barley of a mixed quality, and then screen it, only reserving the stout grain for their own use, that the same thing should be done by the farmer, because he alone has any special use for the thin grain. Messrs. Ransome, Head, & Jefferies offer very effective corn and seed screens. These different screens are good and useful in the hands of men who understand their usage.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Much good tillage has lately been done by the horses, especially where the steam cultivator had been first employed in the heavy work of early spring. Steam power can scarcely be estimated always by the cost, for it not only does a lot of heavy work in a short time and whilst the weather may be favourable, but it eases the labour for the horses if we look still further, and the seed-time is forwarded. We were yesterday giving orders to the manager on our farm to this effect—The Yellow Globe Mangold seed and also Carrot seed must be drilled not later than the 14th of May, the Swedes not later than the 14th of June, and the hybrid and Red Mammoth Turnips not later than the 14th of July. In arranging matters beforehand in this way, and by anticipating the work to be done, the matter is easy of accomplishment in ordinary seasons. We have also purchased all the artificial manures required, and also the seeds required beforehand, so that no delay may occur at the seedtime. Our provision for manure and seed has been as follows:—Yard dung laid out and spread and ploughed in on the flat; in addition we drill 2 cwt. of prepared Mangold manure with 20 bushels of ashes per acre. For both Swedes and Turnips we shall drill 2 cwt. dissolved bones and 2 cwt. Turnip manure with ashes per acre. Our object is simply that the manure should act immediately upon the young plants, for they often suffer from fly or wireworm when young. The bones are intended to carry the crop to maturity, and to insure a good quality roots. We grow Imperial Purple-top Swedes as being hardy and capable of standing the winter and still maintain their value, especially if clamped or pitted in the field. We are very partial to the Scotch yellow hybrid Turnip of the green round variety, and the Red Mammoth Turnip. The latter grows fast, and yields a heavy crop of the greatest feeding value, keeping sound until Christmas and some time after. On the 25th April we finished sowing both Wheat and Barley with Clover seeds. After harrowing the land was rolled on the surface, and the rains which have since fallen will greatly assist the germination of the seeds.

*Hand Labour.*—Men are employed in spreading dung, in preparing artificial manure, such as guano, for the best guano often contains very hard lumps. It is, however, important that all should be passed through a half-inch sieve. Men and women have been and will be still employed in carting and burning Couch when ashes are required for drilling purposes; otherwise, we prefer to cart the Couch away to heap. This plan not only gives a heap of good materials for dressing pasture land, but enables the work to proceed should the weather prove adverse to burning.

*Live Stock.*—The horned Somerset and Dorset cross-bred lambs have been sold, and the ewes also, except where very early lambs are required, in which case we retain those ewes which are lowest in condition, but especially those which lambed latest. We select for them a good Hampshire down ram, and retain none for lambing except those which will drop their lambs before the 20th of November next. The dairy cows and young cattle for stores or for fattening may now lie out at night without much injury from night frosts, for it is

usually safe on dry pasture or parkland. The sheep have done well lately, because the weather has been dry; and where they have fed on the water meadows, in conjunction with Rye on the arable, supplemented by oilcake, the animals have turned out in fair condition, especially the breeding flocks of ewes and lambs. Upon farms, however without water meadows Italian Rye grass and Mangold are the great and valuable substitutes; in fact, both these may be considered the best food to prevent scarcity. We note, also, that farmers who adopt this plan of spring-feeding their sheep have lately sown Mangold seed after the Rye. They will plough and press the land after Italian Rye grass and sow early Turnips, Rape, or Thousand-headed Kale, feeding off by sheep, and sow the land with Wheat early in the autumn.

#### VARIETIES.

**NIGHTINGALES NEAR LONDON.**—A correspondent sends us the following in reply to the request of "WYLD SAVAGE."—"Nightingales used to sing in the lanes near Holland Park; perhaps now the builders have startled them off. I believe they are still heard in Epping Forest, and I hear that a few birds come nearly to the neighbourhood of Dulwich and Norwood." A correspondent, whose address we have forwarded to "WYLD SAVAGE," also states that the Nightingale may be heard any evening in the neighbourhood of Cheshunt. "J. S." writes to us as follows:—"If 'WYLD SAVAGE' would go to Richmond, near to the Star and Garter Hotel, he would hear plenty of Nightingales either by day or night. I lived at Petersham for nine years, and often heard a most delightful concert on a quiet night between Petersham and the Star and Garter." Another correspondent says:—" 'WYLD SAVAGE' need not go further from town than Richmond Park to hear the Nightingale's songs in perfection; indeed, when staying at a house at Kingston-on-Hill, close to the Park walls, we have wished the untiring little songsters further, for they neither slept themselves nor allowed us to sleep, so loud was their nocturnal concert." "A TAMED SAVAGE" states these birds abound near Chislehurst, and Mr. Pasley writes: "There are numbers of Nightingales in full song any evening after ten o'clock on Sheen Common (ten minutes walk from Mortlake station.)" We are also informed that for many years the Nightingale has been annually heard in the Royal Gardens, Kew, and neighbourhood.

— **A PECULIAR CHICKEN.**—An American correspondent states in a recent issue of "Science Gossip" that he has had "a chicken having four legs, four wings, two necks, and one head, or rather two whole chickens with one head; they are joined breast to breast from the base of the breastbone to the end of the necks, where there is but one head, with the top turned to the side; so had it lived it would have eaten from one side. We often hear of chickens having four wings or four legs, and sometimes two heads, but I never heard of one like the above, which was hatched in Clay County, Mo., in 1876, and is now in alcohol in my collection at Kansas City."

— **BRITISH BALLADS.**—Part 4 of the illustrated work on this subject now being issued by Messrs. Cassell, Petter, & Galpin, contains "Brave Lord Willoughby," "The Bridal of Malahide," "The Brownie of Blednoch," "The Burial of Sir John Moore," "The Cane-bottomed Chair," and "Chevy Chace" among others, with well-executed appropriate engravings.

— **BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION.**—At the Council Meeting held at Bristol on April 26th, the draft programme of the forthcoming meeting at Tunbridge Wells was brought up for correction and confirmation. A few alterations were made, chiefly consequent upon the return of the Society to Monday for the opening day of the Show, instead of Wednesday, as at Worcester. Additions were also rendered necessary by the institution of new departments, such as the bee exhibition and the working dairy. The sum of £20 was granted by the Council for the promotion of an exhibition of bees and bee appliances, the arrangements and control being placed in the hands of the Hon. and Rev. J. T. Boscawen. The details of the working dairy were also considered and finally arranged; and the Secretary reported the receipt of donations of £5 from Mr. S. Morley, M.P., and Mr. G. B. Gregory, M.P., respectively, towards defraying the heavy expense incurred by the Society in connection therewith.

— In connection with the National Fisheries Exhibition at

Norwich, the Mayor and Corporation of that City offered a prize of £20 for the best method of treating sewage, chemical and other matter discharged into rivers, so as to render innocuous to fish life. The prize was awarded to the Native Guano Company, Limited, of Aylesbury, by whose A B C process the sewage of that town has been successfully treated for some years. The solid portion of the sewage is converted into native guano, and the effluent water passes off into the river so free of impurity (as shown by analyses) that it is in no way injurious to fish. At the Norwich Exhibition a number of fish were exhibited in a tank filled with the water from Aylesbury sewage, and they appeared perfectly healthy and happy.

#### THE COMING SHOW SEASON.

It is at this season that the committees and managers of shows have to consider their programme for the autumn and winter campaign. Many points have to be carefully weighed, and the best results can only be attained in each case by paying due regard to the special circumstances which govern it. Some of these circumstances are purely local; others, again, are general in their application, but are special in so far as they merely relate to the particular period of the year at which the show is held, or to the success or non-success which has attended the hatching operations of the season. We desire to direct attention to a few of these matters, and shall be glad to receive information from our readers as to any which we may omit. There are in the course of the year from 250 to 300 exhibitions of poultry and Pigeons held in the United Kingdom. Many of these are of real importance, and it is desirable that as to them the sphere of competition should not be in any way limited. Many more are such very minor affairs, both in respect of prize money and classification, that they are at once stamped as local. There is, however, a third class of show, which seems to hang in the balance between the leading and the minor show, and which, we think, loses much from its position of uncertainty. In this class of show the prize money is considerable and the classification tolerably extensive, but neither is liberal enough to place the show in the foremost rank. The result is, that while leading exhibitors of each breed are not attracted in any numbers, the men of several breeds who keep a team for such opportunities as these send in their entries, swoop down upon the prizes, and carry them away from the local fanciers who have expended labour and cash upon the promotion of the show. It is true that these extensive prizewinners pay numerous entry fees, and thus in the first instance bring in funds to the exchequer, and it is also true that the exhibits are often of such a high standard that the eyes of the local fanciers are by seeing them opened to the shortcomings of their own specimens. We admit that these arguments are not without weight, but we must at the same time confess that we think them fallacious. The gain in entrance money is generally merely temporary, and leads to heavy ultimate loss. When it is generally known that Mr. A or Mr. B has become a regular exhibitor in certain classes, and as regularly carries off the prize money, the local exhibitors begin to fight shy of the affair, and prefer rather to send their birds, if good enough, to a leading show for the sake of the notice they may obtain, than to exhibit year after year at home, where anything less than a prize is no great honour, and the chance of winning a prize from the travelling celebrity is slight. As to the other argument to which we have referred, we can only say that we think the majority of fanciers in these days of easy locomotion can always find an opportunity of visiting a really important show, and thus acquiring by a cheaper and more satisfactory method the necessary knowledge as to the merits or demerits of their own specimens. The supposed local Swan is a harmless bird in its own vicinity, and when brought into contact with the world at large is speedily taught that after all it is a mere Goose; but in order to acquire this knowledge it is not necessary or expedient that it should undertake the entertainment of a flock of the genuine breed.

Be it understood that we have not a word to say against the men who thus seek to turn an honest penny by prizewinning. The prizes are there, and are open to general competition. Why, then, should they not win them if they can? It is true that their birds are often merely purchased specimens acquired for the very purpose of prizewinning, and that the prices put upon them are to the local fancier quite prohibitive; but what of that? These

exhibitors are generally too careful of their own interests to allow the birds to get out of condition, and, apart from any cruelty in overshadowing, no other charge can be laid at their doors. The remedy, if remedy be necessary, lies in the hands of the committees of such shows. Let them well consider in the first place whether the position and importance of their locality and the amount of prize money at their disposal is such that a general open competition can be expected. If they decide that the show cannot be expected to take a really important position, we would counsel them then to so frame their prize list that the mere pot-hunters will be excluded. This can be done in several ways. The first and perhaps the most satisfactory method is to limit the competition to a certain area. The next best method is to make the prizes numerous but small in amount. This can be done by increasing the number of the classes, or merely increasing the number of the prizes in each class. In no case should the first prize exceed £1; and if there be £3 to award to a class, five prizes of £1, 15s., 12s. 6d., 7s. 6d., and 5s. respectively would, we think, secure a far better local entry than the usual three of £1 10s., £1, and 10s., and would at the same time offer less temptation to the commercial prizewinner, to whom a good margin over entry and cost of carriage is a necessity.

Another consideration should also be kept prominently in view—namely, whether more real good might not be done by an amalgamation with some neighbouring show or shows, and the formation in this way of one really important show in the place of several mere minor affairs which are mutually destructive to each other. We know that local jealousies are often very bitter, and that such jealousy is by no means absent from the fancier's breast; still in many cases by mutual concessions or by an arrangement that the united show shall be held in each locality in turn, the difficulties in the way may be removed, and several weakly bantlings may be succeeded by one more robust and enduring creation.

The question of classification should in all, except the most important shows, be greatly influenced by the local popularity of each breed. The experience of former seasons where available, the entries in other neighbouring shows, and the individual knowledge of the committee must be looked to for guidance here. A rule is used by some shows that if there be not a certain number of entries in a class, that class shall be cancelled and the entries returned. We hardly think this rule deserves general adoption. A better plan seems to us to be the more usual one of withholding certain of the prizes if there be less than a named number of entries; but even this is open to objection, and should only be used as a tentative and not as a permanent measure. The chicken classes, especially at the early shows, are much affected by the hatching results of the season, and as many accounts which have reached us so far are of an unfavourable character, we would urge upon the committees the necessity of prudence and full inquiry before offering too liberal schedules. We know that the breeders who have triumphed over the difficulties of a severe season think it hard that they should be deprived of any part of their reward, but for the show committee other considerations are necessarily paramount.

One word in conclusion as to speculative shows. These are generally got up by one or two individuals, who hope for a profit, and have no intention of bearing any share of a loss should such arise. Respectable persons frequently allow their names to be made use of by such speculators, and then think themselves hardly used when called upon to make up a deficit. Every means is adopted to avoid payment, and in some cases prizewinners are asked to forego a portion of their winnings. This is most unfair, and we cannot too strongly condemn the dishonesty of the speculative promoters and the carelessness and laxity of those who, by allowing their names to be made use of in such ways, enable this species of fraud to be perpetrated. No show ought to be held unless there be means available to meet a possible loss. Of course, exceptional cases will sometimes occur in aid of which subscriptions may be reasonably solicited, but these should be rare indeed—far more rare than they actually are.

#### STANDARDS OF EXCELLENCE.

IN your issue of April 14th appeared a letter signed "BUFF," raising the question, "Are tricolored Buff (Cochin) cocks to be admitted to the prize list?" The writer, while appealing to those of your readers who are fanciers of the breed to give their ideas on the subject, says, "My experience has been that such birds do not breed evenly coloured pullets, and I think that the uniformity of colour, which is admittedly indispensable in the one sex, should be equally insisted upon in regard to the other." In this short letter I find a great deal suggestive of various in-

teresting points to every fancier and judge of poultry. Firstly, of course, it would be well to know the opinions of some of the great Cochin fanciers as to the colours which correspond in the two sexes of Buff Cochins, and whether tricolored cocks do really produce hens of uneven colour; but beyond this a wide field of interest is opened in connection with "standards of excellence" for poultry, which, it seems to me, in the case of many other breeds as well as this, if they are to be really useful must contain some statement as to the particular points which in one sex go with particular points in the other. If I may I will attempt to expand my meaning a little upon both these headings.

1, The Buff Cochin question. I regret much that up to the present time nothing has appeared in your pages from the pens of those really experienced in the variety in response to "BUFF's" appeal. An admirer and at times a breeder of Buff Cochins I have long been, since days when as a child I was presented with a pair from one of the earlier imported stocks (which, by-the-by, I always believe to have been very good Cochins in form though wanting the size of the now exhibited birds) up to the present time; but to that real and intimate acquaintance with the breed which at once detects the special excellencies or defects which a bird is likely to transmit to its progeny I can lay no claim, and would therefore gladly learn of those who have such knowledge and are sufficiently public-spirited to publish it. As a judge I have not infrequently had some difficulty in placing Buff cocks of the colour or rather colours described to my own satisfaction. It has always seemed to me that a soft uniformity of colouring is one of the chief characteristics of this breed, and consequently that sharp contrasts of shade are out of place in it. At the same time I have often seen the said tricolored cocks so pre-eminently magnificent in form and size that it has been impossible to exclude them from the prize list. Such difficulties must often occur to judges of poultry. Of course the best state of things would be that a judge should only adjudicate upon those classes which he has himself bred carefully; this, however, is obviously impossible, and it therefore becomes the duty of all who agree to officiate in such a capacity to do their utmost to obtain the best information on all such points as that raised by "BUFF"—viz., whether such cocks do produce hens of an objectionable colour. As one who may perhaps be called upon again to award the prizes in classes of Buff Cochins, I should be glad to gain information from those thoroughly competent to give it.

2, This brings us to the larger question of standards of excellence. At the last general meeting of the Poultry Club a resolution was passed to the effect that it is desirable for a new standard to be drawn up. How far that resolution can be practically carried out has, I believe, been lately discussed by the Committee of the Club. Various untoward events have prevented my attending its meetings, and so I write in ignorance of any decision that may have been arrived at. Much may be said for and against the standards of excellence; what, however, I endeavoured in November to impress upon the general meeting I venture now to repeat—viz., that if a standard is drawn up it must be done with so much thoroughness and care, and in the case of each variety by so thoroughly representative a committee of practical breeders, that it may be generally accepted not only by those fanciers who breed but by those who judge poultry. Judges are and ever must be independent of such standards, and so if they are arbitrary or narrow can well afford to disregard them; at the same time I cannot but think that if one were drawn up in a comprehensive and reasonable way it might be a great aid to breeders and judges alike. What suggests itself to me both from the letter of "BUFF" and from my own experience is, that any standard would be imperfect which did not point out the corresponding points in the two sexes of each breed. Considerable latitude might be allowed for fancy, and in some cases great variety of plumage, but there should be some indication of the points which differences in the one sex necessitate in the other. Some of the standards we now have are very good as far as they go—i.e., of the breeds comprised in them they give a good account of what is generally considered a perfect exhibition cock and a perfect exhibition hen; but there is unfortunately this drawback to them, that practically in some cases the perfect cock and perfect hen belong to two sub-varieties, which mated together will not breed both sexes in perfection, and sometimes neither of them. There is no hint in any standard that I know, of the (to experts) well-known fact that in the case of several breeds separate pens are mated for the production of cocks and hens. To be of use to breeders a standard should at least contain some statement of this fact, and to be of use to judges it should explain the connection between the required points in each sex which have brought about this state of things. Arbitrary and absurd

requirements might then no longer be insisted upon, and much good would have been done to useful poultry breeding. Such discussions as that invited by "BUFF" help to clear the way towards a really good "standard," and I earnestly hope that his appeal may not be left unanswered.—O. E. CRESSWELL.

### THE POULTRY CLUB.

A MEETING of the Committee of the Poultry Club was held at Charing Cross Hotel on the 27th of April. There were present the Hon. and Rev. F. G. Dutton (in the chair), the Hon. and Rev. A. Baillie-Hamilton, the Rev. E. H. Morgan, and Messrs. T. W. Anns, R. A. Boissier, A. Comyns, J. C. Fraser, S. Lucas, and T. P. Lyon.

**NEW MEMBERS.**—The following new members were elected:—William Proctor Collier, Seamount, Malahide, Co. Dublin; Robert Watson Cowen, Dalston, Carlisle; Capt. Heaton, Worsley; George Vigers, Hersham, Walton-on-Thames. The following new Associate Members were elected:—C. R. Haddesley, Caistor; W. S. Marsh, Winkland Oaks, Deal; G. V. S. Shaw, Edgeworth Rectory, Cirencester; Harold A. Silvester, Hurn Lodge, Beverley; Samuel Taylor, Moorgreen, Notts; Mrs. R. J. Wade, How End, Windermere.

**CIRCULAR TO FANCIERS.**—The Secretary reported that 7537 circulars addressed to the persons whose names appeared in the poultry section of the "Fanciers' Directory" had been issued, and that a copy of the rules of the Club and a list of the officers and members thereof had been sent with each circular.

**CIRCULAR TO SECRETARIES OF SHOWS.**—The Secretary reported that over two hundred circulars addressed to secretaries of shows, in conformity with the resolution passed at the general meeting, had been issued, but that owing to the difficulty of obtaining the necessary addresses a good many shows had been omitted.

**SUBSCRIPTIONS IN ARREAR.**—The Secretary reported that notwithstanding the issue of two notices requesting payment of subscriptions still due for 1880, several members and associates had neither sent in their subscriptions nor given notice of retirement. It was resolved that in the case of all persons whose subscriptions for 1880 shall remain unpaid at the date of the next meeting of the committee without any explanation having been given, their names shall be then announced as struck off the list of members.

**STANDARD OF EXCELLENCE.**—The Secretary reported that the Sub-Committee appointed at the last meeting had met three times, and had prepared the following report:—

Your Sub-committee have considered the best means of obtaining the necessary data for the preparation of a standard of excellence, and have come to the conclusion that the following course will be a suitable one to adopt.

1. To send out to a number of leading breeders and exhibitors of each variety a blank form of standard, with a circular requesting them to fill up the same.
2. That a draft standard of each variety be formulated upon the basis of the replies received.
3. That copies of such draft standard be sent to the leading poultry judges, with a request that they will comment upon the same.
4. That copies of such draft standard be published in the leading poultry papers.
5. That the standard be finally settled by a committee to be appointed at the annual meeting.

Your Committee have prepared blank forms of standards of each breed, and also a form of circular to be addressed to those fanciers whom it is proposed to consult, also a list of names of those they consider it most desirable to consult as to each breed.

Where any breed is represented by a club your Committee suggest that the standard of such club shall be accepted in the first instance.

The report was after some discussion approved and adopted, and it was resolved that the Sub-committee should be re-appointed for the purpose of issuing the circulars and preparing a report upon the replies received thereto.

**VOTES IN COMMITTEE.**—It was proposed by Mr. Lyon, "That when in any case the decision of the Committee is not unanimous the Secretary be directed in his report to the papers to give the names of those members voting each way."

This proposal was not, however, seconded, and thus fell through.

**OWNERS BIDDING AT SHOWS.**—Notice was given that at the next meeting of the Committee a resolution will be proposed by Mr. Fraser, and seconded by the Rev. E. H. Morgan, to the following effect:—"That the resolution passed at the meeting of the Committee held on the 28th March last, condemning the practice of owners being permitted by poultry show committees to bid for and buy in their own exhibits, be amended by inserting the words 'of birds entered in selling classes' after the word 'owners.'"

**NEXT COMMITTEE MEETING.**—The date of the next meeting of the Committee was fixed for Friday, June 3rd, instead of Monday, May 30th, the date previously announced.—ALEX. COMYNS, *Hon. Sec. Poultry Club, 47, Chancery Lane, May 2nd, 1881.*

The following are copies of the circulars recently issued by the Secretary of the Poultry Club.

#### No. 1.

In accordance with a Resolution passed at the Annual General Meeting of the Poultry Club held on the 16th November last, I beg to enclose a copy of the

rules of the Club, and to direct your attention to the objects for which it was formed. These objects are as follows:—

- (1.) The promotion of the breeding and exhibition of poultry.
- (2.) The suppression of fraud and dishonourable conduct therein; and
- (3.) The advancement and protection of the interests of poultry breeders and exhibitors.

#### No. 2.

A Resolution was passed at the Annual General Meeting of the Poultry Club, held on the 16th November, that—

"A circular be sent to the secretaries of the various poultry shows in the United Kingdom, requesting them to communicate with the Secretary of the Club as early as possible as to the dates of their shows in the season 1881-82, with a view to ascertain if, and how far, any of such shows are likely to clash; and, if possible, to obviate such clashing."

You will oblige me if you will kindly let me know as early as possible the date on which it is intended to hold the — show during the ensuing season.

The first was addressed to all persons whose names appeared in the poultry section of the "Fanciers' Directory" for 1880; the second to the secretaries of poultry shows. We see by the report of the recent Committee Meeting of the Club that, owing to a difficulty as to obtaining addresses, some secretaries of shows have not had copies sent them. It may be well for these gentlemen to furnish the desired information to the Secretary of the Club.

### OUR LETTER BOX.

**Address (James Foot).**—The address you require is Mr. Edwin Crook, Carnaby Street, Regent Street, London.

**Treatment of Goslings (G. S.).**—The method of rearing the Chinese Goose and Canada Goose is not materially different from that adopted with the more common kinds. The goslings should for the first few days be kept warm and dry, and fed upon hard-boiled eggs and bread crumbs or rice well mixed up with some green food, such as young green onions (of which they are especially fond) or grass. This food may in a few days be changed by substitution of barley meal or oatmeal and middlings for the eggs, rice, and bread crumbs. India meal may also be given occasionally. The mother should be cooped after a day or two on a grass run, so that the goslings can have access to the grass. They will at first require five or six feeds daily, but the number may be decreased gradually until they are fledged, when grass will form their staple food, and they will only require a small meal of grain or meal once or twice a day. When the goslings are pretty hardy the mother may be allowed to range with them, and the gander will aid her in protecting them. They may then be allowed to swim in a pond for a short time daily, but it is not safe to give them complete liberty in this respect until they are fledged. Ordinary rain will not hurt them, but long exposure to very heavy rains, especially for the first week or two, should be avoided. It is not safe to trust to the mother protecting them from rats; they should be shut up securely at night until fledged. Their food should not be mixed in such a very liquid state as that they can daub themselves with it, and by the use of long narrow troughs as feeding vessels any risk from that cause can be avoided.

**Canker in Pigeons (Suburban).**—The disease affecting your young Pigeons is that known as canker. As it prevails throughout your loft it evidently depends on some general cause. You are either feeding the birds on unwholesome food, or, what is more probable, your loft or pigeon-house is overcrowded, the dirt is allowed to accumulate, or there is insufficient ventilation. Look well after the general health, and you will have no more canker. The safest application to those birds already cankered is powdered burnt alum, to be applied after removing the white matter.

**Canary Dying (G. Walker).**—It is impossible without details of symptoms, &c., to tell the cause of your Canary's death, or to recommend treatment for the other. From the appearance of the body we suspect internal inflammation, and fear there is something wrong with your system of feeding. You had better purchase some work treating upon Canaries. You can have "The Canary and Other Song Birds," post free from our office for 1s. 7d.

#### REMARKS.

- 24th.—Mild calm pleasant day with some bright sunshine; overcast at intervals.  
 25th.—Fair and warm; very slight shower in forenoon.  
 26th.—Cool, slight showers; shower of soft hail at noon; lightning and thunder at 1.35 P.M.; gusty wind.  
 27th.—Fine, overcast at intervals.  
 28th.—Fine bright morning; dark and stormy-looking from 1 P.M. till 3 P.M.; fine evening.  
 29th.—Fair, but dull and close.  
 30th.—Warm and fine till 5.30 P.M. then slight rain.

On the whole rather a dull week; rain threatening almost constantly, though very little fell. Mean temperature about 6° higher than that of the preceding week.—G. J. SYMONS.

## DISBUDDING.

**D**ISBUDDING is the removal of growths not only not necessary, but absolutely prejudicial to the perfecting of the present and future crops of fruit. It may be contended that no disbudding occurs in nature; but no one can fail to see that the strong outgrow and destroy the weak, until the most crowded branches are rendered destitute of buds by the exclusion of light and air. We do not find acorns in the interior of spreading Oaks, nor Apples in the centre of an unpruned Apple tree, but the fruit is borne on parts enjoying full exposure to the sun.

Disbudding as an art of culture is essential; first, to prevent the production of parts not required; second, to prevent waste of alimentary matter; and third, to preserve the symmetry of the trees.

Disbudding is considered essential in the successful cultivation of plants or trees. All are agreed as to its necessity for producing superior flowers or fruit, excepting a small minority who are better satisfied with quantity than quality. Such will cling to a cluster of three small Roses, just as if one exhibition bloom was not better; and to standard fruit trees as the only method of obtaining profitable results. But those holding these views are in a minority, by far the greater majority preferring, and most worthily, to produce the highest examples of culture. Summer pruning may be disbelieved in or neglected, and growths allowed to be made that will rob whilst active, and be cut away when at rest after the mischief is done. The disbudder acts differently; he allows no new parts to be formed but those essential to the formation of the tree, the perfecting of the present crop of fruit, and making provision for future crops.

It is only of late years that disbudding and summer pruning have become part of the practice of cultivators. I am old enough to remember when those operations were almost nil, and the winter pruning and nailing of fruit trees no pleasant operation. Happily things are changed. The minds of some may linger over the "good old times," but few, I imagine, would like a return to them, certainly not to old-fashioned winter pruning, which can only have this much said in its favour, that provision was made in summer for plenty of work in winter.

It is generally conceded that disbudding exercises a check upon the growth, especially of the roots, from the well-known circumstance of there being reciprocal action between the roots in the soil and the growth above ground. Examine a plant, herbaceous or ligneous, when starting into growth, and its roots

will be found in a more active state than appears necessary for the requirements of the plants at that time. If this were not the case any operation interfering with the roots would not be better performed when the growth was completed, yet whilst there is foliage to induce the emission of fresh roots so that the plant or tree may feel no loss of them, as would be the case if the operation were done between the fall of the leaf and starting into growth. Transplanting fruit trees or lifting and transplanting Vines is not advisable in spring, because there are no active roots then, but the stored-up sap in ripened wood is usually sufficient to maintain vitality until food-supplying roots are formed. Ripe wood cuttings will root although every bud be removed; therefore leaf-development is not absolutely essential to root-formation, and unless this were the fact disbudding would be attended by disastrous consequences. Such, however, is not my experience when the work is carefully done; it is only when done roughly and thoughtlessly by the ruthless removal of many growths and much foliage at one operation that the practice is injurious, as is shown in the Peach by the fruit dropping, in the Vine by the Grapes shanking, and in the Cucumber by the fruit gangrening and being stunted and deformed.

Yet, while I do not advise anyone to leave a well-used road for a smooth untried byepath, I have been led to venture on what may seem a departure from the principles of disbudding by deviating somewhat from the stereotyped advice given on the subject—namely, "Don't be in a hurry in disbudding, and only remove a few shoots at a time." Now, in Peach and Nectarine trees there are shoots that have only a wood bud or two at their base and another at the extremity, and between those are fruit buds, usually single. As a rule the blossoms on such set much better than on stronger shoots with triple buds—i.e., two fruit buds, and a wood bud between them. A shoot of the former has only three wood buds, and of the latter a dozen, or even a score, whilst the difference in the number of fruit buds is not material. Clearly growth is not essential to secure a good set with the weak shoot, and if we remove every wood bud on a level with the bloom buds we secure a better set of fruit than with a growing shoot between every pair of blossoms. The set is not, therefore, dependant on the growth being allowed to extend to produce root action, for I apprehend the petals do more for the organs of fructification than any amount of leaf-development. To remove all the wood buds on a level with or above the blossom is, of course, fatal to the crop, and is only alluded to as showing that leaf-growth does little or nothing towards aiding the blossom of the Peach and Nectarine to set. A little consideration will show that this very early disbudding is not really in conflict with the principles above mentioned, as removing the buds before the foliage has formed cannot be regarded as removing a large quantity at one time. On the contrary, it prevents the necessity or excuse for that dangerous practice; it prevents also the strong leaf-growth appropriating the sap that is required by the embryo fruit; therefore I submit it is sound practice to remove very early a portion of the wood buds where they abound amongst the blossom. As soon, therefore, as the buds commence swelling I begin disbudding, and by the time the flowers are fully expanded I have no more growths advancing than are necessary to effect the maturity of the fruit and to make provision for future crops. This is simply to have a growth at the base of the present bearing wood and another

above the highest blossom or level with it, the shoots at the base, 15 to 18 inches asunder, providing for the due furnishing of the tree, the branches of which are from 12 to 15 inches apart. As before stated, there is no check to the system of the plant, as would be the case were growth allowed to be made and afterwards removed; but the nutritious elements are reserved for the present crop, and the production of those only for future use.

Similar remarks apply to Vines. No cultivator would tolerate longer growth of the shoots than is necessary to ascertain the fruitful and best breaks, for every growth in the shoot that must come away takes from the vigour of that retained. It is so with Roses. Weakly buds are removed, so that the more promising shall have the support the weak growths would if retained appropriate, and the same principle applies to every plant or tree the flowers or fruit of which are desired of the highest excellence. To effect superior results concentration must be made of the supporting elements upon the object in view; the full forces of the plant must be exerted in abstracting food from the soil, and assimilating the same by the full exposure of the foliage to light and air.—G. ABBEY.

#### ASTERS, MARIGOLDS, AND VERBENAS.

THESE are flowers which I highly esteem, and I would not like to be without a representative collection of them. The culture of each is by no means difficult, and they are certain to repay any care bestowed on them. The two first-named receive exactly the same treatment. We sow the seeds not earlier than the middle of April in cold brick frames, allowing a light for each sort of Aster grown, the spaces being marked off with a stick, and the seeds sown thinly between these marked lines. The young seedlings have thus plenty of room for development. Any rich light soil may be employed; a thin layer of old Mushroom bed manure placed in the bottom of the bed being a suitable foundation, and the seeds merely require covering with some of the sifted soil. Mats thrown over the light to afford shade is all that is necessary until the seedlings are through the soil, when ventilation must be attended to and the mats dispensed with. A wet day towards the end of May is chosen on which to transplant the seedlings in their permanent positions, care being exercised to save as many roots as possible. A mixture of soil and water about the consistency of paint is prepared, and the roots of the plants are drawn through this. If the weather is dry shallow drills are drawn and water is run down each; this keeps any dry surface soil from falling into the holes made by the dibber. The mud paint keeps the roots fresh whilst the plants are becoming established. If a little old dung can be placed over the beds there will be no necessity for supplying water more than once or twice. I find such a mulching of the greatest advantage to many plants. Our Aster ground is always deeply trenched and well manured in the early part of winter. The distance from row to row should be 15 inches, and between the plants from 9 to 12 inches.

I only grow four varieties—viz., Betteridge's Quilled, Victoria, reflexed; Truffaut's Paony-flowered, sent to me this season as the best incurved variety; and the Dwarf Chrysanthemum-flowered Aster. In staking short stout sticks are inserted along each row, to which a strong string is fastened; the plants are secured by a single tie to the string. The quilled varieties are the only ones which as a rule require any support. Where extra fine flowers are desired it will be well to limit the number of flowers to half a dozen on each plant, removing all the side buds. Not only the colours of the flowers but the florets themselves are so much injured by a shower that it is necessary to cover with glass those blooms intended for exhibition. This is easily accomplished by placing sashes over the beds, but the best results may be obtained with wide-mouthed tumblers one above each of the finest blooms. It is also necessary to shade them from the sun. Asters amply repay for "dressing;" in fact, a very good but rough flower has no chance beside a smaller one which has been dressed. The same remark applies to African and French Marigolds. These require a larger amount of space for development than Asters—about 24 inches by 18 being close enough. It is somewhat difficult to obtain a good strain of these, consequently when such has been secured some of the best flowers should be preserved for seed.

I always grow named Verbenas. They may be cultivated either in beds or in pots; if in beds a rich soil with mulchings of decayed dung are needed to induce Verbenas to make strong healthy growth. I have never had them do well except under the above conditions. Plants from cuttings struck about the middle of April are the best for placing out towards the end of

May. They may be planted a foot apart, or 2 feet if the plants can be allowed time to cover the ground. If they are making about five young growths when planted out it will only be necessary to thin out the side growths if they are likely to become crowded. Flowers for exhibition should be covered each with a small square of glass painted with milk and whiting to shade them from sun.

Cuttings for stock plants to stand the winter should be inserted in a cold frame not later than the second week in August. One plant of each sort is quite sufficient to keep, and during winter they should be slowly growing. In pots for flowering they are sometimes unsatisfactory. What they require is a very rich open soil, the pots to be not larger than 6 or 7 inches in diameter, and the plants thrive in a similar temperature to that required by Fuchsias. Mildew and green fly must never be allowed to increase, as both are certain to destroy the plants in a very short time. Liquid manure is very necessary. To those who have not grown Verbenas a dozen or two of the best kinds would prove welcome. I occasionally send for a few per post to nurserymen who make these a speciality, and would advise those desirous of growing them to do the same.—R. P. BROTHERSTON.

#### FRUIT TREES GROWN ON "NATURE'S PLAN,"

##### MR. SIMPSON'S EXPLANATIONS.

It is agreeable to know that Mr. Simpson admits the review to which he refers is "fair and impartial." The explanation he has tendered relative to the non-engraving of the "extension" Peach tree planted in 1866 is perfectly satisfactory, but that he should regard such a tree as grown on "Nature's plan" is not a little extraordinary.

To state that the tree he has described on page 354 "belies" the results that have been attributed as the ultimate outcome of "Nature's plan" is applying a strong term to support an argument that is obviously founded on false premises. If your correspondent seriously thinks that horticultural readers will regard a tree that has been planted fifteen years, and until two years ago has been restricted in growth, a fair type of "Nature's plan," he does not pay a high compliment to their judgment. The tree is 32 feet wide, which means the branches are 16 feet long—a lateral extension that has been reached in fifteen years. It would be a wonder indeed if an "extension" tree thus restricted had branches naked at the base.

Mr. Simpson has certainly weakened his case by adducing such a tree as that (which is no doubt good in itself and all that Mr. Fowler has said of it) as a "living contradiction" of the operation of a law of Nature according to which trees in a natural state become, when of matured age, destitute of foliage at the base of the branches. Most boys in their bird-nesting days know that such was the case then as it is the case now, and will continue as long as trees are permitted to attain maturity without being checked by accident or restricted by artificial means.

As Mr. Simpson has submitted an example of what he terms the "extension" system, it will be fair to allude to some examples of Peach culture on what he would term the "restrictive" plan—trees that have been regularly and systematically pruned. The writer has planted and trained a Peach tree that attained a lateral extension of 60 feet. The branches of this pruned tree were 30 feet long, and were produced in rather less time than that in which those of the "extension" tree referred to grew 16 feet. A tree, not planted by the writer, but by a gardener from whom he gained valuable lessons in Peach culture, proved on measurement to have a spread of 90 feet. The particulars of these trees are known by the Editor. Thus we have "extension" (non-pruned) and "restriction" (pruned) trees side by side, and we arrive at the amusing result that trees have been grown on the latter system with a lateral spread twice as great as the tree adduced as a type of the former. There is evidently a mistake somewhere: it is easy to point out. Mr. Simpson's tree is a mixing-up of restriction and extension; and although it may be a most excellent specimen, to regard it as grown on "Nature's plan" is a self-evident fallacy.

Our author's remarks on Vines call for no comment. A method which in Mr. Simpson's hands may prove successful might be a failure if followed by others who do not so well comprehend it.

Your correspondent wishes it to be known that he "does not condemn pruning." That is quite clear. No one on reading his book can accuse him of doing so. There is sufficient of condemnation in it without that, tempered, however, and hedged by qualifications in such a manner that he has no right to complain if doubts are left on the minds of readers as to the precise nature of the lessons he seeks to inculcate.—YOUR REVIEWER.

LOOK AFTER THE GRUBS.—In his amusing and practical paper in the "Rosarian's Year Book for 1881," my excellent friend the

Rev. H. B. Biron says, "One word of parting advice. There is an enemy which you must meet in the early spring; worse than mildew, worse than aphid, worse than sawfly, worse than Rose beetle, worse than ants—yes, worse than all these together; and that is the bud-worm. Search for him carefully: he does his mischief silently but so surely." And in a letter I had from him the other day he says, "Fine weather for the caterpillars! I killed fifty of the little beggars on two plants of Le Havre, and doubtless there are more left;" and from other quarters I have had notice of the abundance of this enemy, so now is the time to make the onslaught. They are very tiny at present, and are the more easily killed.—D., Deal.

#### PINK ZONAL PELARGONIUMS.

THE abundant flowers of the magnificent variety Lady Sheffield have been well described as possessing a combination of violet, purple, and pink hues. Its trusses are very large, and so freely produced that the plants when in bloom are literally masses of flowers. It merits extensive culture both for specimen plants in pots and for beds, where it is certain to be much liked, large masses of it having a singularly bold and striking effect.

While looking lately over such pink-flowered varieties as I have blooming in pots, I asked my young friend, who last year chose *Stephanotis* as "the sweetest flower that blows," to select the best pink *Pelargonium*. She soon chose Mrs. Leavers, a deep rosy pink of a much more cheerful tone than Lady Sheffield, and with such fine trusses of large handsome flowers that preference will probably be given it by many others. "But," said I, putting a plant of my favourite, Mrs. Wright, beside it, "surely you overlooked this?" "Oh, that is lovely!" was the answer, followed by a request for the plant itself, which was eventually carried off to be cherished as a treasure. These three varieties were raised by Pearson, and they form a charming trio which I cordially recommend to general notice. Mrs. Wright is probably most valued for pot culture from the good form of its bright pink flowers. The trusses are of medium size, which renders them of especial value as cut flowers.

From several other varieties *Parnassus* may be selected as possessing distinct and striking characteristics. It is of the Nosegay type, has abundant large trusses of deep pink narrow-petalled flowers, is of a compact bushy habit of growth, and has handsome well-marked foliage, all which render it worthy to take rank among our best bedding varieties.

All these are infinitely superior to our old friend Christine, and yet it is questionable if any of them are so eagerly sought after or so briskly propagated as it was. When it was introduced bedding-out was at its zenith, and Christine was regarded as a gem of the first water, without which no combination of colours was complete. But now who would give it a second glance except those of us who remember that its advent marked an era in the development of its class?—EDWARD LUCKHURST.

#### RANUNCULUSES.

AN extensive family of mostly showy plants, which give the name to the whole order. Many of them are too inconspicuous to find a place in cultivated ground, but even some of these in a state of nature are perfectly charming. As an example take the *R. bulbosus*, which we all as children have gathered handfulls, by the name of Buttercups, Kingcups, or Goldencups. In the present day, however, we have such a number of really grand kinds to select from, that these old and individually inferior forms must give place. Ranunculuses are numerous and widely spread. Some are aquatics, and all love moist situations, although the alpine kinds must have good drainage, or the least stagnation will kill them. Little more need be said respecting their cultivation, as it is extremely simple, and good loamy soil will suit the border kinds, whilst the Alpines should be planted in a mixture of peat, loam, and river sand. All the species are more or less acrid.

*R. aconitifolius*.—This is a large-growing species, in good soil attaining a height of 2 to 3 feet, and although rather coarse is a fine old border plant. Its leaves are palmately divided; lower leaves stalked, upper ones sessile. Stems branching, producing an abundance of large pure white flowers. It prefers shade. May and June. Alps of Europe.

*R. aconitifolius flore-pleno*.—An old-fashioned border plant, far less seen than it deserves. The flowers are not very large, but are very double and pure white. This variety is the "Bouton d'Argent" of the French, and was well known some years ago in English gardens by the name of "Fair Maids of France." No

garden should lack this charming and useful flower. May and June. Alps of Europe.

*R. acris flore-pleno*.—The "Boutons d'Or" of our French neighbours, yellow "Bachelor's Buttons" of English gardens, is a double-flowered form of an English species plentiful in all pastures. It grows about 2 feet high, and the flowers are extremely useful for cutting, forming a pretty contrast with the pure white of the preceding variety. May to July. Britain.

*R. alpestris*.—A dwarf neat species, which must be placed on some sheltered spot in the rock garden where it is not liable to be overrun with coarser-growing plants; but it should be so placed that it is exposed to the sun during some portion of the day. It usually attains a height of 3 to 4 inches, and becomes tufted. Leaves stalked, roundish, and deeply three-lobed, colour deep shining green. Flowers mostly solitary and pure white. April and May. Native of Tyrol and various other mountainous parts of Europe.

*R. amplexicaulis*.—A very distinct and handsome plant, usually

Fig. 83.—*Ranunculus amplexicaulis*.

about 12 inches high. Leaves entire, ovate lanceolate in shape, the bases clasping the stem. Scape much branched, which, together with the peduncles, are quite smooth. Flowers pure white, in some varieties stained with yellow towards the base. April and May. Alps of Europe. The woodcut represents a spray from a plant of this species growing on the rockery at Chiswick, where its large white flowers are very freely produced, and are very attractive. These are also useful for cutting, as they remain in good condition for a much longer period than the majority of single-flowered Ranunculuses, and wherever simple flowers are appreciated the plant should be grown.

*R. asiaticus*.—This species has received the attention of the hybridiser, and its varieties have become florist flowers, the beauty of which it is scarcely possible to adequately describe. Although not suitable for the rock garden we could not pass them by in silence, because if planted in clumps in the border

during the month of February they produce handsome blooms, and are very effective during early summer. The species originally came from the Levant.

*R. bulbosus flore-pleno*.—This is a double form of the "Buttercup," the flowers resembling somewhat those of *R. acris* fl.-pl.; but the present variety is not more than half the height, so that those wanting a dwarf form can be accommodated. April to June. Britain.

*R. cortusae-folius*.—This is a very fine species, although a tall grower; it is, moreover, somewhat tender as far as our experience extends. The usual height is 3 to 4 feet. The radical leaves are stalked, somewhat cordate in shape, and unequally lobed. Stem leaves much divided into lanceolate segments, whilst the upper ones are entire. The flowers are yellow, large, and spreading, produced in dense corymbs. It is also known by the name of *R. grandiflorus*. April to June. Canary Islands.

*R. glacialis*.—If we had to mention the somewhat tender constitution of the last-named plant, we have in the present species just the extreme, for it grows naturally high up in the mountain regions of Europe, near the limits of perpetual snow. Like all plants from great elevations it is dwarf in habit, usually about 6 inches high, but sometimes reaching to 9 or 10 inches when growing lower down the mountains. The radical leaves are stalked, palmately divided, deep green; peduncle mostly one to two-flowered, but sometimes more are developed. Flowers large, pure white inside, but tinged with purplish rose on the exterior. May. Alps of Europe.

*R. gramineus*.—Although a native of the mountains of our own country, this plant is sufficiently distinct and beautiful to find a place in the cultivated rock garden. It grows about a foot high, with sessile, entire, narrow, grass-like leaves. Flowers large and showy, yellow. April and May. Mountains of Wales.

*R. Gouani*.—This is a fine border plant and a very distinct species. It grows from 12 to 18 inches high. The radical leaves stalked, unequally lobed; stem leaves sessile, palmate, bright green. Flowers large, solitary, bright shining yellow. May. Pyrenees.

*R. montanus*.—A little gem for the rockery. It is tufted in habit, and seldom exceeds 3 to 4 inches in height. The radical leaves are tripartite, bright shining green; stem leaves sessile, with linear segments. Flowers very large, solitary, and brilliant yellow. May. Alps of Europe.

*R. parnassifolius*.—There is something so thoroughly distinct in the habit of this plant that an ordinary observer would never think it is a Buttercup. It attains a height of 6 to 9 inches. Radical leaves entire, stalked, subcordate, dark brownish green, and leathery in texture; stem leaves sessile, ovate lanceolate. Spike branching, bearing several large pure white flowers. May and June. Pyrenees.

*R. rutae-folius*.—Here we have another dwarf-growing distinct plant. The leaves are pinnate with multifid lobes, which give them altogether quite a different appearance to the Crowfoot family. The stems attain a height of about 6 inches, and are usually single-flowered. The individual flowers are very large, and are composed of numerous petals; the colour is pure white, with orange-yellow centre. May. S. Europe.—H.

#### TRAINING PEACH TREES.

THE Journal is always so crammed with practical articles that one often feels shy in taking up a subject. However, I should like to have a few lines, if you can spare space, on the subject mooted by Mr. Pettigrew at page 327. With regard to the system of training lately designated "extension," there is no doubt of its having been in constant application in some gardens for many years. Last spring I visited Mr. Shearer, then gardener at Yester. He showed me a Peach tree, certainly the best trained I have yet seen, thinly furnished with young stout shoots from top to bottom and end to end of the house, and with a stem I took for half a century's growth, and he planted it about thirty years ago, and under the system he employed it was as robust as a tree of five summers' growth. Nevertheless, up to late years I do not think the non-shortening system has been common. Now, however, many young gardeners are working their Peach trees on this principle.

I should not like to dispute Mr. Pettigrew's assertion that trees trained to a trellis under the glass give the best results; at the same time large crops are a certainty every year with trees planted on back walls, provided the house is light and heated. In our own case we could not wish for larger crops than we gather year after year from trees under these conditions; and we are just enlarging an old Peach house, which had trees trained close under the glass, and will have the back wall covered with trees,

and an "old-fashioned turned-over trellis in front." We secure one-third more space for training than is possible under the other plan. The house is a lean-to, and will be 18 feet wide. It was found after calculating the results in various ways of training that the plan adopted would be best.—R. P. BROTHERSTON.

#### NOTES ON PHLOXES.

AMONGST all hardy flowers I find none so useful as these. Their culture is easy, while their rich and variedly coloured flowers are always welcome. For a considerable time back I have annually added fifty plants to our stock, and I intend following up this system.

The present time is the best in the year for making such provision as will insure a display of these plants during the summer months, and those who secure a good selection now may rely on being amply repaid in a few months by a rich harvest of flowers. Plants only propagated last autumn and placed in the borders now will bear one or more spikes of bloom before the season is over, and others divided will soon become as useful as if they had never been disturbed. Indeed I think it is much the surest way of inducing plants to grow after being divided if this operation is deferred until growth has well commenced. Then it is not necessary to take up the whole of the plant to be divided, but the soil may be cleared away from the stems, and the root and the young plants be taken without removing the centre. Varieties of the least merit are hardly ever divided, but remove them to positions of the least importance, and fill up the places they occupied with better forms. Work of this kind should be attended to at once. We always obtain our new Phloxes in small pots; sometimes they have commenced growing, at other times no growth is visible, but such we always keep in a cold frame or sheltered nook until well started, when they are planted out. Some kinds bloom early, others late. Some are tall, others dwarf. Position and culture will not wholly change their characters in these respects, but in sunny places many will bloom earlier than they would do in a shady position. All soil for Phloxes should be deeply dug and well manured. When this is done the after culture for several years will be of little importance, and at all events manure dug in between the plants will be sufficient to insure their development.

Their present culture should consist of dividing the plants to increase stock on making new plantations with young plants. After planting, if the weather is dry one good watering should be given at the roots, and before growth has become so tall as to be broken by the wind a stake should be placed to each, and tying should be done at intervals as necessary. Where extra fine spikes are required for exhibition or any other purpose a dressing of strong manure should be spread round the stems, and all the weakest stems should be cut out close to the bottom and only the strongest be allowed to grow. For exhibition we have sometimes only had two spikes from a strong root, but for general decorative purposes every shoot may be allowed to grow and flower. As many of your readers will soon be filling their flower garden beds for the summer, it may not be out of place to say that for the centres of beds no plants are better suited than Phloxes, and if the best early and late varieties are planted together they will produce a mass of flowers during a long period.

Phloxes are not grown so extensively as they deserve, especially for park and general decoration, and no doubt they will receive much more attention in the future. The following names of some of the best varieties in cultivation may be useful to some readers:—Dwarf early varieties: Mrs. Morrison and Mrs. Garrett. Taller varieties: Beauty of Edinburgh, George Eyles, Redbraes, Mrs. Guthrie, President, Mrs. Ritchie, Mrs. Miller, and Indian Chief. Late varieties: Henry Cannell, James Cocker, Professor Blackie, Thomas Swanston, Pilrig Park, John Forbes, David Thomson, James Mackay, Jennie Grieve, J. Muir, and David Syme. It may be mentioned that these are chiefly seedlings which have been produced by Messrs. Dickson & Co., and are welcome additions to this favourite flower.—W. M.

THE EGGS OF THE VAPOURER MOTH (*ORGYIA ANTIQUA*).—There is hardly a garden where in the winter season one may not detect on a bough, stem, or perhaps on a wall or paling, the cocoon of the female insect studded with the eggs that are to hatch in spring. By an odd error of instinct, the caterpillar will in its wanderings fix the cocoon it spins in a corner away from foliage, the result being, as I have several times noticed, that the young brood die of starvation. When it has become of some size, the peripatetic powers of the Vapourer caterpillar would win the approbation of a walking Stewart, though, when first hatched, as is usually the case with caterpillars, they cannot make any

progress until they have eaten. One of the few caterpillars that can eat almost any leaf that is handy, it is yet not sufficiently abundant to require measures for its extermination in our gardens, where its colouring and its brushes of hair make it conspicuous on shrubs or trees. I refer to it more particularly to suggest as a subject for inquiry, whether it is occasionally eaten by insect-loving birds? I believe so. And I would note how curious is the fact that this species is distributed everywhere, although the females cannot fly or crawl; therefore this is due to the wandering habit of the caterpillars, seldom to that unintended transference by man's agency which has helped to make some insects common.—C.

#### PLANTS RECENTLY CERTIFICATED AT REGENT'S PARK.

At the last Exhibition of the Royal Botanic Society at Regent's Park a number of plants were honoured with certificates, and as we were unable to accord space for their description in the report of the Show a few notes indicating the characters of the plants will be acceptable.

Botanical certificates were awarded to Messrs. Veitch & Sons, Chelsea, for the following:—*Dracæna Lindenii*, a very distinct plant, with leaves 8 to 9 inches long, about 3 inches broad, streaked with green and a yellowish tint, slightly arching or recurved. It will probably prove useful for decorative purposes. *Goniophlebium lachnopus*, *Asparagus tenuissimus*, *Aralia Kerchoviana*, and *Davallia elegans polydactyla*, which were also certificated at Kensington on the day previous, and described in our issue of the 28th ult. To Mr. B. S. Williams, Upper Holloway, for *Croton Lady Zetland*, a beautiful variety with gracefully arching leaves, 8 to 12 inches long and 1 inch broad, bright red in the centre, margined with dark green and bright yellow. This *Croton* appears to colour very well in a young state. *Philodendron elegans*.—A neat Aroid. Leaves 10 inches long, several inches less in breadth, pinnatifid or almost pinnate, the segments narrow and light green. To the General Horticultural Company, Regent Street and Anerley, for *Rhodea japonica aurea*, a hardy variegated plant, which, however, succeeds in pots, and is useful for green-houses or conservatories: the leaves are 10 inches to a foot long, about 2 in breadth, slightly drooping, and striped with green, yellow, and white; *Dracæna Alexandra*.—Elliptical leaves, 3 or 4 inches broad, dark green centre and white margins; *Dracæna Rossi*.—A variety of neat habit, with fine dark crimson foliage; *Dracæna Recurva*.—Fine broad leaves, streaked with green and bright pink; *Cyperus laxus variegatus*.—A prettily variegated *Cyperus*, which was certificated last year by the Royal Horticultural Society—the specimen shown at Regent's Park was in excellent condition, and proved that the honours which have been accorded it were well merited; *Caladium Frederick Bause*.—A very dwarf and distinct *Caladium*; the leaves 4 or 5 inches long and 3 broad, very bright shining red in the centre, neatly margined with green. The height of the plant shown scarcely exceeded 6 inches, and if it continues as dwarf as that it would make a good companion for the favourite *Caladium argyrites* in the front row of groups of plants. To Mr. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, for *Agave Parryi*, a dwarf form, with short glaucous leaves arranged in a rosette-like manner; *Agave Huntii*.—Leaves pale green, yellow in the centre, and the margin devoid of spines; *Yucca Peacockii*.—A distinct species with long narrow leaves a foot or more in length; *Odontoglossum crispum grandiflorum*.—A handsome variety, bearing large flowers spotted with bright chocolate.

Floricultural certificates were awarded to Messrs. Paul & Son, Cheshunt, for *Rose Ferdinand Chaffolte*, a Hybrid Perpetual variety with large dark crimson flowers of good form. To Mr. C. Turner, Slough, for *Auricula Mrs. William Brown* (Turner), a white-edged variety with dark body colour; flowers symmetrical, and truss compact. Also for the Alpine varieties *Philip Frost*, purple shaded, white centre; *John Ball*, bright maroon, deep yellow centre; and *Lizzie*, rich purple shaded, light yellow centre. To Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, for *Auricula Hilda*, a fine green-edged variety, with large flowers of excellent form and black body colour. To Mr. R. T. Veitch, Exeter, for *Rhododendron exoniense*, described last week. To Messrs. Fisher, Son, & Sibray for *Rhododendron Lady Alice Fitzwilliam*, described on page 336 of the present volume; and to the General Horticultural Company for *Gloxinia Mrs. Bause*, a handsome variety with erect, large, well-formed flowers of good substance; white, with a ring of pink in the throat.

**LICHENS ON FRUIT TREES.**—Mr. W. Thomas asks me to explain the reason why it is that Keswick Codlin Apple trees are covered

almost completely with lichens and other parasites, whereas on the Winterbox planted side by side with the Keswicks not the slightest trace of lichens is to be seen. It seems very curious. Perhaps readers of the Journal can explain. Both trees are the same age—viz., fifteen years.—W. ROBERTS.

#### GARDENERS' ROYAL BENEVOLENT SOCIETY.

A SUB-COMMITTEE was formed last year to consider a proposal for increasing the pensions of the Institution, and for raising the amount required for carrying out that excellent project. Having obtained the opinions of a number of representative horticulturists and estimated the cost of carrying out the scheme, the Committee decided to recommend the following resolutions for adoption:

- 1, That it is desirable that the pensions given by this Institution should be increased to £20 and £16 respectively.
- 2, That having regard to the large majority of answers from the gentlemen whose opinion was solicited, and the estimated expenses for carrying out the scheme suggested by the Secretary, they recommend that a simultaneous collection be made in every garden and horticultural establishment in Great Britain and Ireland on Saturday the 30th July next.
- 3, That the fund thus proposed to be raised be designated "The Gardeners' Benevolent Pension Augmentation Fund."
- 4, That the amount raised be kept separate and distinct from the general fund, and be invested in the names of trustees, and the interest thereon be reinvested until such time as the Committee shall see fit to recommend to the subscribers an augmentation of the pension.
- 5, That in the event of the scheme proving successful it be continued annually.

The Sub-Committee in arriving at these conclusions have given the subject referred to them their anxious and earnest deliberations, and they feel convinced that if the gardeners generally will only give the Committee their assistance and co-operation the success of the appeal is not only certain, but it will be the means of bringing the Institution prominently before the notice of many who are unacquainted with it, and adding considerably to its annual revenue.

Should this report be adopted your Committee recommend the re-appointment of a Sub-Committee, with powers given it to carry out the scheme and arrange details.

The various forms, &c.—viz., the original letter, the collecting card, &c., are appended.—JOHN LEE (*Chairman*), ROBERT A. OSBORN, J. WILLARD, W. H. GULLIFORD, H. DICKSON. April 21st, 1881.

We trust that a scheme so worthy, and which appears to us of great practical importance, will be adopted, and we trust that a spirit of emulation will be incited in gardens throughout the country in carrying it out. If all head and under gardeners will contribute their mites, even if these are individually small, a substantial—even a noble—sum may be provided for an object that cannot fail to commend itself to all thoughtful men. We earnestly hope that the effort that is being made will prove eminently successful, and will receive the sympathy and active co-operation of the class in whose behalf it is instituted—namely, aiding in the hour of necessity gardeners and widows of gardeners in this country.

#### ODDS AND ENDS.

**Forced Strawberries.**—Mr. Abbey has found that Vicomtesse Héricart de Thury has not been quite satisfactory for early use. I have found it most serviceable. The difficulty is, that it often forms a number of small crowns late in the season; if these are prevented, or removed promptly, the central crown is the finer and the crop better. Dr. Hogg for ripening now is one of the finest, large, good in colour and rich in flavour. These two varieties I am informed have been remarkably fine this year at Stillyans, the residence of Lady Dorothy Nevill, as grown by Mr. Vair the gardener. Plants of the first-named variety that have been forced early and the foliage kept in good condition will, if partially shaken out, repotted, and properly attended to, produce fine crops in the autumn; in fact they will often do so if planted out in rich soil in the open garden. La Grosse Sucrée is very extensively and successfully grown in the Royal Gardens, Frogmore, and it is undoubtedly a valuable variety for forcing.—J.

**Noblesse Peach for Early Forcing.**—That this variety is not equal to Royal George for certainty of crop will not be disputed, but it sets and swells as freely as any other at an early season. It certainly has one great fault—viz., dropping its buds, and very vigorous trees have twin, triple, and sometimes more pistils to a flower. Grosse Mignonne also has the latter peculiarity. Under less forcing the defect of dropping the buds is reduced, also the monstrous pistils are not so marked; and outside—i.e., against a wall, it does not drop a bud, the flowers have not more than one pistil, nor are there any flowers almost devoid of petals, nor the pistil so short as not to rise above the anthers, as is common with trees

subjected to early forcing. Considering its very superior quality it is valuable for forcing to ripen in early June; indeed for flavour it has no equal, and in setting it is fully equal to any, Royal George excepted.

*Budding Established Peach and Nectarine Trees.*—It sometimes happens that varieties are planted which are not true to name, or the sorts are not suited for the purpose. Instead of removing the trees to give place to young trees, buds of some approved kind may be inserted in the current year's young wood as near to their base as practicable, and the growths having proper attention will afford a change of kind in a couple of years without loss of crop in the meanwhile. This method is also applicable where a long succession of fruit from one tree is desired, which is often advisable when the demand is moderate. It is better to have three or more varieties on one tree which can be allowed fair extension than the same number of trees when there is really but room for one. Granted a tree of Royal George to occupy a trellis 12 feet by 10 feet, or it may be twice the area, or 240 square feet, a sixth may be budded with Early Beatrice to afford a few dishes of fruit six weeks in advance of Royal George; another sixth with Early Alfred or Hale's Early, which will follow in fourteen to twenty-one days; a third sixth with A Bee, coming in after the other two in a similar time; a fourth sixth Royal George; a fifth sixth with Violette Hâtive, succeeding Royal George; and the sixth and last part with Stirling Castle; this will give a succession during eight to ten weeks. If to those mentioned be added Grosse Mignonne, Noblesse, Bellegarde, Dymond, Barrington, and Late Admirable, we have a dozen of the choicest and most reliable Peaches for any purpose. Nectarines may be changed in a similar manner; Peaches may be inserted in Nectarine trees, and *vice versa*. Lord Napier, Stanwick Elruge, Violette Hâtive, Humboldt, and Victoria are good Nectarines.

*Sulphuring Hot-water Pipes for Destroying Red Spider.*—This pest has had a fine time, the cold weather having necessitated more fire heat than usual where early forcing is practised, and precluded the employment of sufficient moisture. For destroying this insect fumes of sulphur are mostly effectual, flowers of sulphur being formed into a thin cream with skim milk and applied with a brush to the pipes when at a temperature of not less than 160°. If the pipes in the house have to be kept at a high temperature there is danger in applying the mixture to the flow pipes freely, as the fumes will injure the foliage and skin of the Grapes. I wish to draw attention to the effect of the fumes on different kinds of Grapes, for the berries of Hamburgs and those which have not a Muscat flavour are not injuriously affected, and black Muscat Grapes are not affected so much as those with white skins. When stoning is completed strong sulphur fumes cause the berries to assume at first a leaden, and afterwards as the ripening advances a bluish or purplish tinge, especially near the footstalk, giving them the appearance not infrequent in Grizzly Frontignan. How is this?—G. A.

#### ROSES AT REGENT'S PARK.

MESSRS. WM. PAUL & SON of Waltham Cross now have their customary exhibition of Roses in pots at the Royal Botanic Society's Gardens, and rarely have the plants been seen in better health than they are on this occasion. Two hundred and fifty specimens are shown, mostly in 10 or 12-inch pots, with clean, well-developed, vigorous foliage, each plant bearing from eighteen to two dozen blooms, the colours of which are as clear, bright, and fresh as could be desired. Owing, however, to the position the plants occupy in the corridor being rather too much exposed to the sun, and the awning employed to shade them being scarcely heavy enough, the majority of the blooms have become somewhat too fully opened, and in consequence their distinctive characters cannot be seen to the best advantage. On the opposite side of the corridor, which is much more shaded, a number of smaller specimens in 8-inch pots represent some of the chief new varieties, and on these the flowers are excellent in size, form, substance, and colours. In addition to these, twelve boxes of cut blooms are shown in similarly satisfactory condition.

A large number of varieties are represented, including many novelties as well as the older favourites. Among the newer forms two unnamed seedlings are noticeable—one with neat well-formed blooms, something in the way of Duchess of Bedford, but of a darker colour; the other has very broad rounded petals of good substance, and very dark crimson in colour. Both appear to be really fine dark-coloured Roses. Of the other new Hybrid Perpetuals William Warden is noteworthy for its handsome pink blooms, the petals of great size, the flower being generally full and of excellent substance. Souvenir de Madame Robert is another

pretty pink variety; while Crown Prince and Pride of Waltham, with many others, well maintain the credit of the firm. A new Tea named Dr. Berthet, with a beautiful blush-tinted flower suggestive of Souvenir d'un Ami also attracted much attention from the visitors.

The most noteworthy among the older varieties were Baron de Bonstettin, Xavier Olibo, Magna Charta, Dupuy Jamain, Etienne Levet, Camille Bernardin, Paul Neyron, Victor Verdier, and Lælia, of the Hybrid Perpetuals; and among the Teas were some good examples of President and Niphetos, some flowers of the latter having been of extraordinary size. The arrangement of the plants has been carefully performed, and the general effect is highly satisfactory.

#### HINTS ON RAISING PLANTS FROM SEED.

GENERAL directions on this subject are nearly as difficult and perhaps as dangerous as on the kindred subject of watering, no two cases being exactly similar. The difficulty is not diminished at present (April 22nd), when there is a cold, searching, north-east wind blowing, a few hours' exposure to which would greatly injure any tender plant. To make matters worse the temperature is 10° less than the week previous. I have no doubt it is lower, and the effect of the weather more injurious in the north of Ireland, some parts of England, and the whole of Scotland too. Those living in southern valleys sheltered from the northerly blasts enjoy a warmer climate. I am acquainted with a few gardens fully exposed; and when the climatic influences are as at present, the temperature behind the house—northerly, is always 10° less than at front—looking south. Now such considerations and observations are very important for those with limited appliances and limited time when raising plants from seeds, which so many are doing now. What complicates all this is the influence of the sun. While writing there is no sunshine—the day might be one in December; yet in half an hour the sun may come out in full force, raise the temperature of greenhouse or frames to 70°, and with moisture scorch the tender expanding leaves of half-hardy plants and cuttings. There is no remedy for this except precaution. A few days since I sowed some valuable Primula seed in pans; and the remainder of the package, which I considered would have made the seed too thick, I put separate. The seed germinated, and in the pans that were slightly covered with moss, which acted as a shade and retained moisture, the seedlings escaped, while the others while moist were caught by strong sunshine and destroyed. The same thing happened to Godetia Lady Albemarle and Browallia elata, which I put outside when the weather came moist and genial a week since. Buying expensive seeds, going to much trouble preparing composts, sowing, and watching for a suitable temperature—all this may be wrecked at a critical moment if persistent attention is not maintained. If kept in a moist frame with a heat not exceeding 65° except from sun heat, and with moss spread on the surface of the pot or pan or a sheet of whitened glass, little watering will be necessary. Watering from a large rose, and especially with hard water, such fine seeds as Tuberous Begonias, Show Auriculas, &c., would be instant death, besides scattering the soil on all sides. Many are uneasy when they do not see such plants as those named coming up rapidly in a fortnight or so. Many of the hardier florists' flowers, even Carnations, Primulas, Pansies, &c., take months before the whole of this have germinated. Geranium seed I sowed in January are still germinating. [Primrose and Polyanthus seeds, especially if dried or kept long without sowing after gathering, will often remain six months before they germinate.

At present I have a quantity of Primula japonica sown last October just coming up—seven months after sowing, and the seed was taken off the heads of the plants fresh. I should strongly recommend amateurs to gather seeds from any novelties that come under their notice, and sow it as soon as ripe. Very few seeds improve by keeping. There are a few vegetable seeds, and I believe Asters, that a year's keeping will not injure—rather give a stocky and more compact habit of growth; but the reference to sowing as above indicated applies to rare plants, and implies that you have the means of keeping them over the winter if necessary, as the autumn is the general season when this recommendation can be taken into effect. Many good plants will grow and live outside during the severest winters. Take a case of a universal favourite, the Pansy. Away on vacation last year, I noticed in a gentleman's garden in Connaught a very curious Pansy. Fortunately there were many pods of almost ripe seed which the head gardener plucked for me. They were completely ripe in my portmanteau when I returned here in August. I sowed them in a box in the open air, and I believe every seed soon germinated. Without any protection except what some fine hay and the snow

gave, those seedlings lived outside last winter, were transplanted in February to a finely prepared bed, and so far, strange as it may seem, the few flowers that have opened are all different from the parent Pansy; and it is one of the sources of pleasure in raising such seedlings to watch what each fast-expanding bloom may be like. The certainty of variety would of course be greater from a mixed package of seed.—W. J. M., *Clonmel*.

#### BRUGMANSIAS.

THESE plants are not very often seen in our greenhouses and conservatories, yet they are well worth a place in such structures. They have a noble appearance when in leaf, and are highly ornamental when in flower. Brugmansias are free and vigorous in habit, and this in my opinion is what is very frequently wanted in many conservatories, as formally trained plants are often too

numerous. They are well suited either for culture in pots or for being planted out. Some time ago we had them in pots and tubs, but now they are all planted out in the conservatory and are greatly admired. When the plants are in good health the leaves are about a foot in length and half this in width, of a beautiful green colour, and all showing a drooping tendency. The flowers are of true trumpet-shape, quite a foot in length, fragrant, and of various colours. Those of *B. Knightii* are double white; *B. suaveolens*, single white; and *B. sanguinea* is scarlet, orange, and green. All hang down like great Fuchsia buds, and they have a grand appearance. One large plant of *B. suaveolens* has been blooming with us for the past ten weeks, and although the flowers do not remain long fresh in a cut state, they were very effective during the early days of spring.

By a little extra attention they may be had in bloom twice or three times during the year. As soon as they have flowered we

Fig. 84.—RHODORA CANADENSIS.

cut the shoots close down to the old wood and allow the young ones to grow up. These flower in a few months, when they are removed in the same way and others take their place. Being very softwooded they grow rapidly, and if they were not cut down in the manner indicated they would soon become too large. Another way of treating them is to cut half the shoots down at one time, and the others when the young growths have made about half their length. This plan prevents the plants from ever having a bare appearance, and it also secures a greater succession of bloom.

I daresay young plants may possibly be obtained from some nurseries, although we never see them advertised. They may also be raised from seed, and cuttings root freely. Like all quick-growing softwooded plants they require a soil of good loam and cow dung. This is the only compost we use for planting them in, but when sand or charcoal is added after the plants have been well established we do not treat them so liberally, as they are likely to

produce a quantity of wood and leaves, and the flowers are not so abundant. Unless the soil is very poor only clear water should be given when the wood is being made, but as soon as the flower buds are visible liquid manure may be supplied. This renders the flowers larger and more fully developed. When plants are in 10 or 12-inch pots they need not be shifted on or repotted for some years, but whenever young growth is being formed a top-dressing of manure will be beneficial.—PRACTITIONER.

#### RHODORA CANADENSIS.

ONE of the prettiest early-flowering deciduous shrubs we have is that represented in the accompanying woodcut, and when in its best condition it is highly attractive. The flowers are of a fine crimson tint, very suggestive of *Azalea amœna*, and are borne in terminal clusters of four to eight each, appearing in late March or early April before the leaves are developed. A few

specimens in front row of shrubbery border, or in the mixed border, have a charming appearance in spring, as the blooms are produced in great abundance, and prove useful for cutting when the supply from other sources is becoming exhausted.

The plant thrives well in ordinary light garden soil, and succeeds admirably in Messrs. Osborns' Fulham Nursery, whence the specimen was obtained represented in the engraving.

#### PORTRAITS OF NEW AND NOTABLE PLANTS.

In briefly pointing out the chief characteristics of the new or remarkable plants figured in the leading scientific publications, it may be useful to some readers if the known or probable cultural value of such plants be indicated; as many, though of considerable interest to botanists, would be of little use in ordinary gardens, where the object is to obtain the best possible display with the least expense. Some, too, even of the really useful species, are not in commerce, and not readily obtainable, as they are often confined to a few botanic gardens. Indeed, it is surprising, that although nurserymen display such energy in introducing new plants, many in botanical collections that would merit a place in any garden are allowed to remain comparatively unnoticed; yet the majority of such establishments now afford the trade every facility in obtaining by exchange any plants that can be readily propagated. Therefore, in addition to such cultural notes as may seem requisite in referring to "Portraits of Plants," attention will be especially directed to any of these neglected plants which may be occasionally figured.

*CRAWFURDIA LUTEO-VIRIDIS*. (*Bot. Mag.*, t. 6539.)—A climbing ally of the *Gentians*, with opposite, ovate, cordate leaves, which become tinged with reddish purple when mature, and axillary or terminal clusters of green and white tubular flowers. The chief attractions of the plant are the brilliant crimson fruits, which are ellipsoid in form and 1 inch to 1½ inch in length. Seeds were sent to Kew in 1879 by Dr. King of the Calcutta Botanic Gardens, and the plants produced flowered early in the present year in a cool pit. Native of the Sikkim Himalayas. The plant would no doubt thrive in an intermediate house or possibly in a greenhouse, and might advantageously receive the attention of cultivators.

*POLYGONUM SACHALINENSE*. (*Ibid.*, t. 6540.)—This is stated by Sir Joseph Hooker to be "by far the noblest species of *Polygonum* known in cultivation, if not the noblest of the genus, forming as it does clumps 6 to 8 feet high and broad, of innumerable rich red-brown wand-like stems that spread and droop gracefully all round, loaded with magnificent leaves which attain a length of 18 inches and a breadth of 10." It is a native of Japan and the island of Sachalin, and was discovered in Amur Land by Maximovicz. It was cultivated in the Moscow Zoological Gardens in 1869, and is believed to have been grown at Kew twenty years ago, "having been probably introduced by one of the Kew collectors in Japan, Mr. Oldham or Mr. Wilford." It increases very fast by the roots, and flowers in September and October. A fine clump of this *Polygonum* has an imposing appearance in Battersea Park.

*MILLETTIA MEGASPERMA*. (*Ibid.*, t. 6541.)—Closely related to *Wistaria sinensis*, differing chiefly in the pods. "It is a tall woody climber, festooning lofty forest trees in its native country—namely, river banks in tropical and subtropical Australia, where its pendulous paniced racemes of bright purple flowers and glossy evergreen leaves must have a beautiful effect." The leaves are pinnate with five pairs of leaflets, and it bears long racemes of flowers, the standard being pinkish, the wings and keel bright purple. First described by Baron Von Mueller, who introduced it to Kew, and a plant flowered in the temperate house there last year. It is well adapted for growing in similar structures, and is very attractive when flowering.

*CLEMATIS AETHUSÆFOLIA* VAR. *LATIFOLIA*. (*Ibid.*, t. 6542.)—A hardy climber, with pinnately divided leaves and small campanulate white flowers about three-quarters of an inch in length. The plant has long been at Kew, and was received from the St. Petersburg Botanic Garden. It flowers in autumn. Native of Amur Land and North China.

*FOURCROYA CUBENSIS* VAR. *INERMIS*. (*Ibid.*, t. 6543.)—A variety of *Fourcroya* from Mr. Wilson Saunders which flowered at Kew last year. Mr. J. G. Baker considers that it only differs from *F. cubensis* in "its less rigid leaves, and by the total or almost entire suppression of their marginal teeth."

*TRICYRTIS MACROPODA*. (*Ibid.*, t. 6544.)—A pretty herbaceous plant, with stem-clasping leaves and corymbs of yellowish flowers dotted with reddish purple. A native of Japan and China. It resembles *T. hirta* (figured in this Journal page 291, vol. xxxvii.) in habit and the form of the leaves, but the latter are not clothed with hairs in *T. macroпода*, and the flowers are smaller.

*CRINUM FORBESIANUM*. (*Ibid.*, t. 6545.)—"A most curious and interesting species of *Crinum*, remarkable for its very large bulbs, short stout scapes, and very large decumbent leaves, not developed fully till after the flowers have faded." It is an ally of *Crinum Kirkii*, and the flowers resemble *C. ornatum* in the red-striped perianth. It was sent to England in 1824 by Mr. J. Forbes, but appears to have been lost until 1877, when Mr. J. J. Monteno sent

bulbs to Kew from the Lebombo Mountains near the eastern coast of Africa, in the latitude of Delagoa Bay.

*ABRONIA LATIFOLIA*. (*Ibid.*, t. 6546.)—A hardy perennial plant which, like its better-known relative *Abronia umbellata*, is included in the natural order *Nyctagineæ*. It has opposite heart-shaped leaves, and axillary umbels of small yellow tubular flowers, with slender prostrate stems. The plant abounds on the shores of Western North America, where it was discovered by Mr. Archibald Menzies in the expedition of Captain Vancouver. It succeeds well in light soil, and frequently flowers at Kew in the late summer months.

*NERINE FILIFOLIA*. (*Ibid.*, t. 6547.)—A new *Nerine* received at Kew in 1880 from Mr. C. Ayres, Cape Town. It is distinguished by the filiform character of its foliage, and has small flowers with narrow spreading rosy crimson petals, the bright colour of which renders the plant very attractive. It is well suited for culture in pots. In describing the plant Mr. J. G. Baker expresses an opinion that *Nerine* cannot be well separated as a genus from *Ammocharis* and *Lycoris*.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held on Tuesday last, Colonel R. Trevor Clarke in the chair, the following candidates were duly elected Fellows—viz., E. H. Bousfield, Henry Chapman, John Omer Cooper, Percy Cooper, W. H. Counsell, Colonel Dunsterville, Arthur J. Edwards, Mrs. Ellis, Mrs. Tyler, Miss Amy C. Galton, Frederick S. Isaac, Thomas Jackson, W. W. Lander, Miss Leyland, Edmund Loder, Lady Agnes Move Nisbett, George Prince, Richard Sisley, Mrs. J. S. Grant Smith, Rev. F. A. Stewart-Savile, Vincent Biscoe Tritton, C. H. B. Whitworth.

— DURING the past few days rather boisterous and dry easterly winds have prevailed, which are very inimical to the SETTING OF FRUIT BLOSSOM. A very large grower of fruit trees remarked to us the other day that these rough and dry winds often do as much injury as frost, as the expanding flowers are forced open prematurely; the petals are thin in texture and blown off before their time, leaving barrenness behind them. There is much truth in that remark; and although fruit blossom is late and has generally escaped injury by frost in the metropolitan district, yet if more genial weather does not speedily occur, with occasional showers, we shall not be surprised if many trees that are so profusely covered with blossoms produce comparatively light crops of fruit.

— IN order that gardeners and others in different parts of the country may note the state of vegetation as compared with that in the neighbourhood of London, it may be stated that LILACS COMMENCED FLOWERING generally in the parks and suburban gardens on the 7th inst. The trees and bushes are now very beautiful, the majority of those of mature age being laden with flowers.

— WE have to record with much regret the death of MR. ROBERT BENBOW—who for the last six years was manager of the seed department at Mr. B. S. Williams's Victoria and Paradise Nurseries, Upper Holloway, N.—which occurred on Thursday night the 5th inst. Mr. Benbow had been for some time in a weak state of health, which was much aggravated by the severe winter and chilly east winds which we have lately experienced. To a thorough knowledge of his business he combined an amiable disposition and a gentleness of manner which won him the esteem and respect of all who came in contact with him. The deceased had only attained the age of forty-one years, and leaves a widow and three children to mourn his untimely end.

— WE observe that BEDDING-OUT has commenced in the

London parks, not only many of the comparatively hardy edging plants having been put out, but also several Pelargoniums. We note, however, they look the reverse of comfortable, both the soil and air being very dry, and the wind brisk and cold. Rain is much needed, and until it comes the placing-out of tender plants cannot be recommended as a safe course to pursue. Those who can adopt a waiting policy in a matter of this kind will probably be gainers in the end, as to nothing does the old adage of "more haste worse speed" apply than to the work of placing tender plants in flower beds, thousands of which will be so-treated during the present month.

— A GARDENER writes as follows upon PLANTING CAULIFLOWERS:—"A useful plan I have adopted in planting Cauliflowers and all the Brassicas is to draw a deep drill or trench, and plant them in that, as it affords great protection to them, and they receive more benefit from the rains. The soil may be drawn round the plants, and the quarters look much neater; besides, the plants succeed better than when planted on the level and the old-fashioned system of earthing them up like Potatoes is adopted."

— THE extent to which flowers are employed has been recently strikingly exemplified by two occurrences—one sad, the other jubilant. For placing on the bier of a late distinguished statesman, the Earl of Beaconsfield, as many wreaths as would fill a waggon were stated to have been sent to Hughenden; and the correspondent of a daily paper has stated that the marriage offerings of the public of Brussels to Princess Stephanie, daughter of the King of the Belgians, took the graceful form of bouquets, of which so many were offered to the Princess on the occasion of her departure from that city that no less than four waggons were required to remove them to the Palace; and we are also informed that the flower merchants of Vienna could not possibly execute half the orders they received for the decoration of that city during the wedding festivities.

— THE value of ZONAL PELARGONIUMS AS CUT FLOWERS is admirably shown by Mr. James McIntosh, whose bulb beds were recently alluded to in this Journal. Ever since last autumn a large round table in his sitting-room has contained about six dozen small Alexandra glasses, each containing one truss of flowers, the stalks inserted through bits of paper containing the names, which, resting just inside the glass tube, can be read through it. These variedly coloured trusses arranged in concentric circles produce a beautiful effect, and an excellent estimate can be formed of the relative merits of the varieties. Among the most striking scarlets were Ferdinand de Lesseps, Remus, and Corsair; Circulator, paler in colour, being highly attractive. Brutus was perhaps the best crimson; Sybil Holden and Lady Emily fine among the pinks; Miss Hamilton a splendid delicate peach colour; Fairest of the Fair, Miss Gladstone, and Evening Star excellent oculated varieties, blush with salmon centre; and White Clipper, a fine if old pure white. These are all worth growing, but it might be that others equal to them would be seen after a rearrangement, for the number of varieties grown is very large.

— A CORRESPONDENT writing to us on the beauty of TULIP BEDS IN LONDON, after referring approvingly to those in the parks and Temple Gardens, states the finest beds he has seen were those of Captain Patton at Langford Place, N.W., which, he says, "a week ago were gorgeous, the blooms of Keyzers Kroon being 18 inches in circumference, white Pottebakker being nearly equally fine; Pourpre Kroon, with variegated foliage, extremely rich; and the doubles La Candeur, Rex Rubrorum, and Tournesol of great excellence. The beds were first planted all over with Crocuses, and just as these faded the Tulips commenced expanding, thus rendering the garden gay for many weeks. The latter were planted about 6 inches apart among the Crocuses, the

foliage of which does not in any way mar the effect of the Tulips. A thick layer of manure was placed a few inches below the bulbs, and to this the very large and fine flowers is attributed."

— THE third portion of Mr. Day's Orchids was sold on the 4th and 5th inst. by Mr. J. C. Stevens, the following being some of the principal prices realised. *Cypripedium Stonei* var. *platytænium*, one strong growth with seven leaves and a young shoot with four leaves, 120 guineas. The only other specimen of this fine variety, it will be remembered, has been previously sold for 140 guineas, Sir Trevor Lawrence being the purchaser; and it was recently stated in the "Gardener" that this price was £42 higher than has been ever obtained for any single Orchid. *Cattleya labiata*, a fine plant of an autumn-flowering variety, with a seed-pod said to have been fertilised with pollen from *Cattleya exoniensis*, 40 guineas. *Masdevallia chimæra*, the true species imported by Mr. Sander in April, 1880, 15 guineas. *M. bella*, very good specimen of excellent variety, 16 guineas. *M. radiosa*, rare, 12 guineas. *Saccolabium guttatum* var. *Holfordianum*, 21 guineas. *Vanda insignis*, the true species of Veitch's importation, 34 guineas. *Aerides Fieldingi*, handsome plant with twenty-six leaves, 22 guineas. *Phalænopsis Wightiana*, rare, 16 guineas. *Saccolabium Turneri*, strong plant, 24 guineas. *Cypripedium Spicerianum*, fine plant, three growths, 42 guineas. *Oncidium ornithorhynchum album*, 36 guineas. *Lælia elegans* var. *Wolstenholmeæ*, 28 guineas; and *Angræcum Ellisi*, a strong plant, 15 guineas. Several *Nepenthes* were also sold, one fine specimen of *N. sanguinea* realising 21 guineas. The total amount obtained for the 659 lots was £1888—higher by £40 than was yielded by either of the preceding sales. The fourth portion will be sold on May the 23rd and 24th.

— PARTICULARS of the following GARDENING APPOINTMENTS have been forwarded to us:—Mr. G. Radford, late gardener to Col. Lambton, Streatham Hill, succeeds Mr. Millard as gardener to Mrs. Gebhardt, Highcroft, Husbands Bosworth, Rugby; Mr. W. Millard having been appointed gardener to Wm. Soper, Esq., Caterham Valley. Mr. Henry King has succeeded Mr. Whorten as gardener to Mrs. Carter, Ospringe House, Faversham, Kent. Mr. F. Southam, recently gardener to the Rev. T. Jeffcott, Farthinghoe Rectory, Northamptonshire, now holds a similar position in the service of J. C. Harter, Esq., The Cedars, Leamington. Mr. W. Manning, late gardener to the Rev. Sir E. G. Moon, Bart., Fetcham Rectory, Leatherhead, succeeds Mr. C. Millard, as gardener to Geo. Taylor, Esq., Hazle Hall, near Epsom; and Mr. J. Paul, recently in the service of C. Weldon, Esq., Morden Hill, Lewisham, has been appointed gardener to George Beer, Esq., Elmwood, Bickley.

— SWEET NANCY.—A correspondent, "J. T.," desires to know the botanical name of a plant that is popularly known in some districts by the above name, and also where he can obtain plants.

#### ROYAL HORTICULTURAL SOCIETY.

MAY 10TH.

EXHIBITS on Tuesday last were not very numerous, though both the Council-room and the conservatory contained some groups of interest and several promising new plants.

FRUIT COMMITTEE.—Harry Veitch, Esq., in the chair. Messrs. C. Lee & Son, Hammersmith, sent three plants of an alpine Strawberry named *Duru*, with long conical bright scarlet fruits, which the Committee desired to see again. Mr. Woodbridge, The Gardens, Syon House, exhibited a dish of Suttons' Scarlet Globe Radish, neat in form and bright in colour, but considered to closely resemble a variety certificated at Chiswick last year as Round Rose Hatif. Mr. A. Mann, St. Vincent's, Grantham, sent a fruit of a new Melon named Sir Garnet Wolseley, of medium size, about 5 inches in diameter, with yellow flesh and well netted, but deficient in flavour. It was stated by the exhibitor to be three weeks earlier than Read's Hybrid, having been in use since the 18th of April. Mr. Mann also sent fruits of Rollisson's Telegraph Cucumber and one named *Excelsior*,

the latter long, of good shape, and bearing moderate bloom. Mr. Buchanan, gardener to Dr. Siemens, Sherwood, Tunbridge Wells, exhibited a fruit of Wm. Tillery Melon grown under the influence of the electric light. It was firm and of good flavour, a cultural commendation being awarded for it. Some Wheat was also shown which had been sown on December the 7th and subsequently grown in the electric light, and it was then over 2 feet high. A vote of thanks was accorded to Mr. Z. Stevens of The Gardens, Trentham, for a bunch of Black Hamburgh Grapes. A collection of Apple flowers of several varieties was sent from the Royal Horticultural Society's Gardens, Chiswick; and Mr. R. T. Veitch, Exeter, sent fine examples of his late white Broccoli Exeter Market.

**FLORAL COMMITTEE.**—W. B. Kellock, Esq., in the chair. Messrs. Veitch & Son exhibited a group of new plants, of which several were certificated and are described below; but in addition to these the following were noteworthy. A *Primula* from Tchang, said to be hardy, with loose umbels of pale purplish white flowers something like the light-coloured varieties of *P. cortusoides*. The leaves were bright green, roundish or heart-shaped, with stalks 3 or 4 inches long. The Committee desired to see it again from out of doors. *Indigofera decora alba* had racemes of white Pea-shaped flowers and light green pinnate leaves—a pretty variety of a well-known plant. *Chionographis japonica*, which was exhibited and certificated last year, was again shown in good condition with two spikes of its curious flowers, the linear irregular petals of which impart a very distinct appearance to the plant. A basket of an excellent dark red Japanese Maple named *Acer polymorphum latifolium atropurpureum* was also contributed, with specimens of *Alpinia albo-vittata variegata* very freely streaked with white. Sir Trevor Lawrence, Bart., sent a plant of *Cypripedium Wallisi* and flowers of *C. caudatum* for comparison, both having very long narrow petals, greenish flowers, and a large white blotch inside the lip; but in *C. caudatum* the lip is tinged with brown, while in the former species it is light green. A plant was also staged as *Cattleya Reineckiana*, but the accuracy of the name was questioned by some members of the Committee. The flowers were fine, with broad white petals and sepals, a large lip with a crisped white margin, crimson centre, and yellow base. A vote of thanks was accorded to Mr. W. Fyfe, gardener to W. F. Dick, Esq., Thames Ditton House, Surrey, for a stand of excellent *Maréchal Niel* Roses.

Messrs. Laing & Co., Forest Hill, contributed a group of *Caladiums* and *Tuberous Begonias*. Among the former *Alfred Bleu*, *Mithridates*, and *Princess Teck* were especially remarkable for the size and bright colour of the leaves, but the Committee wished to see the varieties again, as they were scarcely developed enough to judge of their respective merits. Three beautiful *Begonias* were exhibited, all scarlet—one named *Scarlet Gem*; another, Mr. Alfred Brassey, with broad petals of a very bright tint and neat habit; and the third *Begonia Davisii flore-pleno superba*, which was deservedly certificated and is referred to elsewhere. A *Colcus* named *Mrs. Baxter* with crimson leaves margined with green was shown by the same firm. Colonel Trevor Clarke, Welton Place, Daventry, showed a hybrid *Elisena* bearing two white *Pancratium*-like flowers on a scape 2½ feet high. It was referred to the Scientific Committee. Mr. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, sent a plant of *Masdevallia Harryana*, a very fine variety, the flowers about 2 inches in diameter and rich in colour. Messrs. James Carter & Co., High Holborn, sent a pretty double *Primrose*, and plants of what they termed “a new hybrid *Marguerite Chrysanthemum Prince Rudolph's Bride*,” with white flowers, very like *C. frutescens*, but apparently rather more compact in habit and bearing light green pinnatifid foliage. Mr. R. Dean exhibited specimens of his new dwarf Red Wallflower, very dark in colour and excellent in habit. The strain was commended. A dwarf double yellow variety with small bright-coloured but full flowers was also noticeable. Mr. G. Bethell, Sudbourn Hall, Wickham Market, staged plants of a white variegated *Spiderwort* named *Tradescantia argentea*, and some seedling *Coleuses*; one, *Mrs. Baines*, neat, mottled with crimson green and yellow, and *Mrs. Bethell* with a rosy centre and green and yellow margin. Mr. Harrison Weir, Weirleigh, Brenchley, Kent, sent pretty dark-ground gold-laced *Polyanthuses*, named respectively *Heart's Delight*, *Triumph*, and *Goldfinch*. Mr. James Kelman, Chingford, Essex, exhibited plants of a dwarf Musk with yellow crimson-spotted flowers. Mr. Edward Bland, Cranbourn Court, Winkfield, Berks, staged a plant of a seedling *Anthurium Schertzerianum* with brightly coloured spathes 4 or 5 inches long. Mr. J. Copley Far, Headingley near Leeds, was accorded a vote of thanks for a *Tropæolum*, said to be a seedling from Ball of Fire, which it greatly resembled, but the flowers were perhaps a little larger. Messrs. Rivers and Son of Sawbridgeworth contributed trusses of two seedling *Zonal Pelargoniums*, both with shades of pink with full double flowers; and the Royal Horticultural Society exhibited specimens of the pretty purplish blue *Tropæolum azureum*, and the elegant *Onychium auratum* from the gardens at Chiswick.

In the conservatory the principal group was from Mr. B. S. Williams, Upper Holloway, which comprised an abundance of choice Orchids and other plants, and well merited the silver Flora medal awarded for it. Several *Dendrobes* were especially notable. *D. Griffithianum* having nine fine trusses of bright yellow flowers; *D. fimbriatum oculatum*, also fine; *D. Dalhousianum* with pendulous racemes of large flowers; *D. rhodopterygium*, pale mauve or pinkish; and the well-known *D. Pierardi* were all admirably represented.

*Aspasia lunata* was bearing several flowers; the imposing *Oncidium Marshalli* and the distinct *Epidendrum paniculatum*, with several fine *Masdevallias*, as other beautiful plants, rendered the group highly attractive.

Messrs. Osborn & Son, Fulham, were awarded a silver Banksian medal for a pretty group of stove, greenhouse, and hardy plants. In the centre was a large basket of *Gentiana acaulis* with abundance of brilliant blue flowers, forming by far the most important feature in the collection. Mr. Aldous, South Kensington, staged a miscellaneous collection of decorative plants; and Messrs. Barr & Sugden, Covent Garden, were accorded a silver Banksian medal for their extensive and beautiful collection of *Narcissus* flowers. Mr. Turner, Slough, sent baskets of the richly coloured *Tricolor Pelargonium* Mr. Henry Cox, and a fine double white *Azalea* named *Madeleine*. The latter was extremely fine, some of the flowers exceeding 4 inches in diameter, very full, of good substance, and pure white. Several tastefully arranged groups were also contributed from the Society's gardens, the *Azaleas* and varieties of *Primula cortusoides* being particularly fine.

The following first-class certificates were awarded:—

*Aralia Chabrieri* (Veitch).—A very elegant plant with linear leaves 6 to 8 inches long, dark green, the midrib being dark red. They are arranged in a pinnate manner on the slender branches; and the plant, being compact in habit, has a very neat and pleasing appearance.

*Gloxinia Radiance* (Veitch).—An erect-flowered variety, the flowers of medium size, very smooth, and symmetrical in form; the corolla rich crimson, the tint extending nearly to the base of the tube inside, the outer part very pale pink. It was very free and compact in habit, the leaves 8 inches long by 5 broad, bright green.

*Primrose Cloth of Gold* (Messrs. James Carter & Co.).—An excellent double *Primrose* of dwarf habit, and bearing numerous large pale yellow flowers. The plants shown were from the open ground, and proved how well adapted the plant is for growing as an edging to borders.

*Begonia Davisii flore-pleno superba* (Laing).—Probably the finest double scarlet *Tuberous Begonia* yet in commerce. The flowers exceed 3 inches in diameter, very full of petals, and of a most intense scarlet tint. It is dwarf in habit, and has the small dark green leaves characterising the species.

*Ribes pumilum aureum* (Osborn).—A dwarf *Ribes* only a few inches high, and well suited for pegging down as an edging to beds. The leaves are very small, and possess a well-marked yellow tint.

## ORCHIDS AT KEW.

IN a collection of Orchids similar to that at Kew we always find a few varieties either of botanical interest or horticultural value. The Kew collection, as a matter of course, is composed of almost all kinds, some being of striking beauty, whilst others when in flower are small and inconspicuous.

Amongst the most showy forms that are in flower, the first to arrest the attention of the visitor are some very fine varieties of *Vanda suavis*. The plants are healthy and clothed to the pot rims with thick dark green foliage. In the same house may now be seen in grand condition several remarkably fine specimens of *Epidendrum bicornutum*. These plants are worth going a long way to see, for it is seldom we have an opportunity of seeing this Orchid in flower. There are several good *Dendrobiums* in flower. The first to be mentioned is *D. Dalhousianum*: this species, being so well known, needs little said in its favour. *D. fimbriatum* var. *oculatum* is a good old kind, and will always be appreciated. The flowers in the variety under notice are of great size and substance. *D. barbatulum* is another species now in flower. This is apparently rather scarce. It is supposed by many to be difficult to grow, but it seems to be flourishing and flowering freely at Kew in a shallow pan suspended from the roof. The flowers are pure white and thickly set on a drooping raceme, and would be admirably adapted for cutting. *D. lituiflorum* is flowering in a basket. I do not remember seeing a finer form. *D. mcsachlorum* is by no means a popular plant in Orchid collections, but anyone seeing the plant of the above-named species in flower at Kew could not fail to appreciate it. It is much in the way of *D. Pierardi* in shape, colour, and size of the pseudo-bulbs, but the flowers are much whiter, the sepals and petals are pure white tipped with purple, with a most delicious Violet perfume.

There are several *Oncidiums* in flower. The first on the list in this genus is *O. Krameri*; a very quaintly formed flower. *O. pumilum* is flowering on a piece of cork suspended from the roof, and evidently enjoys the treatment it receives. It apparently belongs to the *luridum* section, for the leaves are very similar but much smaller. There are several racemes; the flowers are hooded, and packed almost as thickly on the raceme as they can stick. *Sobralia macrantha* is doing well and producing numbers of its *Cattleya*-like flowers; the individual flowers last but a short time in perfection, but as the old flowers decay they are succeeded by others which spring from the top

of the matured pseudo-bulbs. *Thunias* are grown well at Kew, *T. alba* being especially noteworthy, and is now making a grand display in the cool house. The bulbs or stems are short and almost as thick as one's thumb; apparently the short stems are the best for flowering. I noticed on one plant where the stems were short and stout they were producing fine racemes of flowers; whilst on another plant the stems were much longer and not nearly so thick, there were no flowers at all. *Pleione Hookeriana* is in excellent condition. This is indeed a little gem; the flowers are a fair size, the sepals and petals being pure white, the scooped-shaped labellum being also white with a dirty brown. There is one variety of *Odontoglossum Pescatorei* which I greatly admired; the flowers are very large and pure white. *O. Pescatorei* usually has some violet markings on the

column and at the base of the labellum, but in this case it is almost or entirely absent. There are several *Cypripediums* flowering freely, and one that is named *C. barbatum* var. *giganteum* is of special merit. The flowers are large, as the name implies; the dorsal sepal is of great breadth and substance, the colouring of the veins being most intense. The above are only a few of the Orchids that are now flowering at Kew.—VISITOR.

#### PRETTY SPRING FLOWERS.

AMONGST spring-flowering plants there are some which have what I may term fugitive blooms—beautiful for a few days and then lost to view and enjoyment for a year. As a type of this class I name *Sanguinaria canadensis*. Others are more durable,

Fig. 85.—CROTON HAWKERI.

and remain in bloom for some weeks. Probably one of the most beautiful when examined are the *Epimediums*, blooms of which I enclose. Here on a limestone foundation they grow freely anywhere. I have them on a barren spot at the foot of an Oak tree, on a rockery, and on an open damp border. In the last they spread most freely; the wax-like flowers are the admiration of all who examine them.

Next them in beauty and length of flowering time comes *Orobis verna* and its varieties. Following in time but more brilliant in colour are the *Gentians*—perfect gems where they like their home, and strange to say they prefer a garden walk of limestone chippings to the rich bed which was provided for them in the adjacent border. Scarcely less bright in colour, but smaller in bloom, of a bright blue, is *Omphalodes verna*, somewhat like the *Forget-me-not* but brighter in colour. There is also a most beautiful flower with a leaf like an *Epimedium*, but with a white wax-like flower

with spurs tipped with purple. I enclose a bloom, which please name.—G. O. S.

[The flower was much crushed and withered; it is probably *Epimedium Perralderianum*.]

#### CROTON HAWKERI.

CROTONS have increased rapidly in numbers of late, many having been imported, some originated by sports, and others the result of cross-fertilisation. A rather close similarity is apparent in several varieties, hence the remark that is not infrequently heard, "there are too many Crotons." Several of the newer forms are, however, highly distinct and decidedly beautiful. The Croton now figured is quite dissimilar from all others that we have seen, and well-grown plants possess a delicacy and chasteness that commands approval. The habit of the plant is very

dwarf and dense, and small plants in 4 or 5-inch pots are charming for table decoration, the colours being such as to show with great advantage under artificial light. The central portion of the leaf is of the palest possible amber, clear and transparent, occasionally approaching white, the margins and tips being deep green. For several decorative purposes *Croton Hawkeri* is a plant of considerable promise, and is worthy of the necessary cultural care to produce it in its best condition. The Floral Committee of the Royal Horticultural Society have placed the stamp of their authority as to the merits of this plant by awarding it a first-class certificate when it was exhibited by Messrs. Veitch a few months since.

#### THE LATE AURICULA SHOW.

I WAS hindered from being present at the late Show at South Kensington owing to parish matters detaining me at home; and as I have not been in the way of seeing any Auricula growers since, the observations I now make are entirely derived from what I have seen in the Journal and other papers; and as I am now unhappily only an outsider I hope it will not be supposed that my remarks are dictated by any "envy, malice, or uncharitableness." In the first place, then, I would ask, Does or does not this, the fourth Show of the Southern Section as it is euphemistically called, of the National Auricula Society, bear out the assertion which I made some years ago, that the cultivation of florists' flowers is at a discount in the south? and have all the very laudable exertions of those who set out to prove that I was wrong been able to bring forward a large accession of exhibitors from the metropolis and from the south of England generally? Well, let us see. There were, as far as I can gather, nine exhibitors—(I do not include Alpines, or Fancy Auriculas, or Polyanthus, or the class for fifty, in which Alpines were allowed to be exhibited)—and of these just one, Mr. Douglas, hailed from the south. Of the others, Mr. Horner and Mr. Simonite were from Yorkshire, Mr. Gorton and Mr. Barlow from Lancashire, Mr. Penson from Shropshire, Mr. Llewelyn from Wales, Mr. Bolton from Cheshire, and Mr. Hay. Amongst these were divided the fifty-one prizes offered, of which Mr. Douglas secured twenty-two, Mr. Horner six, Mr. Penson ten, &c. Now I fail to see in this any proof of the increased interest in the Auricula in the southern portion of the kingdom. People may admire it, may go into raptures over its beauty, may buy plants; but as to the more serious business of exhibiting, I think the publication of these lists fully bears me out in the assertion that in and around the metropolis the zeal there was in the growth of florists' flowers has vanished.

Then I think it evidences how very much the conditions of Auricula-growing are altered. The season was said to be backward, and in fact we know it was; and yet flowers from the very north of England carried off many of the chief honours. They must, then, have been subjected to a considerable amount of heat to bring them forward, and as a consequence, which I see noted in some of the papers, many of the flower stems were drawn, and required what an Auricula ought never to require—a stick to support it.

In looking at the names of those varieties which obtained the prizes a few things are noteworthy. I see in one of the second prizes that Colonel Champneys was included. As a variety that increases rapidly, and from its vigour of constitution as a decorative plant, I have nothing to say against it, but as a Show Auricula it has not anything to commend it. It is utterly despised by the florists of Lancashire. It has a watery eye, an edge that is neither grey nor white, a body colour that runs largely into the edge, and a pip which is cup-shaped instead of flat. Then we see that while the more modern flowers, such as George Lightbody, Lancashire Hero, Alex. Meiklejohn, take very honourable places, they do not quite jostle out the older sorts. Thus in the class of selfs, to which we have a comparatively large number added of late, yet that fine old flower Blackbird took first, third, and fifth prizes, while in whites Sunley Beauty took the first and second prizes, while in the Northern Show such old flowers as Kenyon's Ringleader takes a first place. Now I think this is encouraging to those who cannot afford to pay a guinea a piece for new sorts, as they need not think that because they have not obtained these that they cannot hope to win.

I do not see anywhere any statement as to who the Judges were.—D., Deal.

#### THE UTILITY OF BIRDS IN GARDENS.

BIRDS are so intimately connected with the garden and gardeners that I think they are, as a rule, worthy of being described as beneficial friends. Yet there are many who think the reverse, and some birds are considered useless without the slightest

acknowledgment of the good they do, for I am fully convinced they more than repay us in the end for the mischief they commit at certain times.

The town garden is most likely to suffer from their attacks owing to the scarcity of food. During the recent dry weather I have noticed the sparrows eating the Primroses, chaffinches doing the same with young Turnips, Lettuces, &c. Blackbirds and thrushes, too, have completely stripped the Ivy of its berries, the ground being so dry that worms have retreated out of their reach.

The most familiar and the most persecuted bird is the house sparrow (*Passer domestica*). It is needless to point out its faults, which are well known, but it is my object to show that it does good as well as injury. It has frequently been said, and no doubt is yet believed, that sparrows are not caterpillar eaters, but I have found they are, and they feed their young with such food, which also forms a large portion of their own diet. I have often seen the sparrow venture into the plant houses where Roses, &c., were infested with green fly, often revisiting the house.

The chaffinch (*Fringilla cœlebs*) also feeds on insects to a large extent in summer time, the young being principally fed with caterpillars and aphides; the latter especially I have frequently seen them scrape off the young shoots of Plum trees. They are amongst the most useful birds as ground insect eaters.

Of the Tit family there are four species more useful than injurious—viz., the great tit (*Parus major*), the blue tit (*Parus cæruleus*), the cole tit (*Parus ater*), and the long-tailed tit (*Parus caudatus*). The first two mentioned are addicted to do injury occasionally, and therefore are out of favour with most gardeners. Both of these tits feed their young principally on caterpillars; in fact, it is only on rare occasions they intrude on the gardener's property to do any damage. The cole tit and long-tailed tit are both insectivorous; the first is a great destroyer of caterpillars, feeding the young entirely on them. I have more than once known them nest in a garden wall, and from watching their proceedings I ascertained they were valuable friends. The long-tailed tit is certainly a great destroyer of insects, but is of more benefit to the woodman than the gardener. Yet I have an instance of their doing good on one occasion. In the autumn of 1878 every day a number of the long-tailed tits visited a plantation of Black Currant bushes which were covered with brown fly, which the tits did not cease to visit until all the insects were destroyed.

Among the migratory birds there are many insect eaters. Two of them are much alike in their habits and nature—the blackcap warbler (*Sylvia atricapilla*), and the garden warbler (*Sylvia hortensis*), both of which are guilty of eating Raspberries, but I believe the cause of their doing so is to find the tiny grub that is well known to exist in the fruit; but the havoc the two warblers commit in devouring caterpillars during incubation is enough and more to repay for the spoiling of the Raspberries.

The chiffchaff (*Phyllopneuste hippolais*), is one of the earliest of migratory birds, and the latest to depart. Although the last to mention, it is the most useful of all birds connected with the garden. In the latter part of summer I have seen a dozen in one large Apple tree continually on the search after insects. It appears to me but little known among gardeners, but deserves every protection. There are many other birds of great use to a garden; but sufficient has been mentioned to show that we are indebted more to birds than many persons are aware of, therefore we should protect, not destroy them.—A GARDENER.

#### EXTENSION-TRAINED PEACH TREES—LOW TEMPERATURES FOR VINES.

PERHAPS I should say not a word on this subject, for what the phrase exactly means I do not know. I am not possessed of Mr. Simpson's book, but I think the system, as I understand it from what the critics say, is nearly one hundred years old. To prove this perhaps you will allow me to quote a very old gardener, famed in his own time, and quoted and copied by many since. I refer to Mr. Nicol, who practised in Fifeshire about the end of last century. Speaking of Peach trees in the open air he says, "These trees ought to be trained in the fan manner. It is not practicable to train them to any considerable extent horizontally. . . . The shoots of these often require to be shortened. This is to be understood of such as are hurt by frost (not being fully ripened to their extremities), and more particularly of those from which it is wished to produce a supply of other shoots, either to fill a vacancy or for the extension of the tree." He then goes on to state reasons why shoots should be shortened, and how much they should be under different circumstances, chiefly because of unripened and damaged wood. "Unless for these reasons the middle-sized, hard, and well-ripened shoots which abound in fruit

buds and have a wood bud at their extremity should never be shortened." He also advises disbudding as it is generally understood and practised.

Speaking of Peaches under glass he says, "It is a common practice to shorten every shoot less or more. This may be proper for Peaches growing in the open air, as . . . when the extremities are injured by frost; but it can only be proper in the Peach house to cause wood to push to fill vacancies, or to keep the bottom part of the trellis filled with young wood."—(*Garden Directory*, p. 75.) I cannot give the date of this publication, nor the name of the publisher, as some leaves are wanting; but the following occurs in "The Scots Forcing Gardener," first published in 1797, and which ran through several editions:—"Observe this practice (shortening the shoots) till the trees have filled their places, and afterwards shorten none, unless to fill any casual vacancy." He also recommends planting in October. Peaches he recommends to be planted at 15 feet apart, on open walls 15 feet high, and wider under glass. This seems to me the extension principle with such modifications as must be practised. The materials for, and the manner of making the borders, are precisely what every successful gardener adopts now. Altogether I cannot see that this has been any improvement on old Nicol's system, and we think if he had his due many of our "dons" would own that they had learnt their lessons at Nicol's feet. Certainly no practitioner has advanced a step since his day and nothing new except Rivers' dwarfing system has been submitted. There are only two systems worth mentioning practised at the present day. Wherever roomy houses are erected Nicol's system, with very little modification, is the system practised; with small structures Rivers' system is, or should be, adopted. No one has made any improvement on these systems, for they suit the trees, and until their (the trees) nature alters, altered systems will ever remain what they are—pet notions of the few.

I do not think Mr. Simpson has had justice done him in the matter of low night temperatures for Vines. Nothing in modern times has done so much to produce improved health in Vines and better quality in Grapes, the lowering of night temperatures consequent on his teaching. There may be nothing new under the sun, but the high night temperatures of a few years ago are a thing of the past, because those temperatures were destructive. I do not mean to say that nobody practises the old method, but I know that most of our best growers have abandoned the practice.

I think gardeners are in many instances jealous of each other, and occasionally perverse in consequence. I could name one not unknown gardener who, previous to Mr. Simpson's published strictures on high night temperatures, kept up the temperature of his vineries as much above 70° at night as possible, and who quarrelled with many a good journeyman in cold weather when in the morning the temperature was down to 65°, and who at a dinner in connection with a flower show (just after the discussion on Mr. Simpson's practice) made a speech in which he maintained that he had always kept his vineries at anything between 40° and 55° at night, although that very spring he had parted with his foreman because the latter could not keep up a higher temperature than 65°, even although the man had not been in bed all night, and although the water in the pipes was at boiling point, and a higher temperature an impossibility. Latterly he adopted much lower temperature, I believe because of what Mr. Simpson published, and yet I have heard that man say that while he adopted a high night temperature and abandoned "Simpson's" low one he never had succeeded, whereas the exactly opposite was the case. I do not mean to insinuate that such conduct is common even among gardeners, but occasionally the public are misled by such men, and gardeners sometimes grudge their fellow gardeners any fame they may honestly win, and I think the one who reviewed Mr. Simpson's book showed too much of that spirit.—SINGLE-HANDED.

[Our correspondent is in error respecting the reviewer of the book in question, who did not refer to low temperatures for Vines, nor said so much against Mr. Simpson being the originator of the extension system of training Peach trees as is contained in the above article. Mr. Simpson formed a more just estimate when he described the review as "fair and impartial."—ED.]

**AZALEA INDICA MADELEINE.**—One of the finest double white Azaleas I have yet seen was that shown by Mr. C. Turner at the Royal Horticultural Society's meeting on Tuesday last. The flowers are of great size and substance, very full of petals, and pure white, except for a very slight greenish tint at the base, which is not readily noticeable. The habit also appears very compact, and the variety is altogether a very promising one. It is, I understand, one of Mr. Turner's own raising, and I was also

informed that the plants exhibited at South Kensington last Tuesday were subsequently sold to Mr. B. S. Williams of Upper Holloway. Testimony of the excellence of this variety is afforded by the fact that it was certificated in 1879 by the Royal Horticultural Society.—R.

#### HARDY FRUIT GARDEN.

APRICOT trees have now sufficient foliage to protect the fruit, which is only moderately abundant, and the coverings may be removed, except in low situations; but in such cases it is well to uncover the trees on fine days so as to harden the foliage, which might otherwise be injured by sudden exposure to bright sunshine. Thinning the fruit must also have early attention, removing the smallest and those not well placed. The trees will need attention in removing any foreright and other shoots, it being better to rub off gross shoots than allow them to advance and afterwards seek to restrain their vigour by stopping. Shoots required to form spurs should be pinched at the third leaf, and those for extension must have timely attention in tying or nailing in when sufficiently advanced. Keep a sharp look-out for caterpillars. Peach and Nectarine trees are setting the fruit fairly well and are growing freely. The trees are clean where efficient protection has been provided, which should still be continued on cold nights, and where permanent coverings are employed advantage should be taken of fine days to uncover the trees. Disbudding will also soon require attention, commencing with the more forward growths, and to do so gradually so as not to check the action of the sap, as would result from disbudding the whole of the tree at once after the growth is somewhat advanced. Some care and judgment is necessary to supply the trees with young shoots for next season, bearing in mind that the Peach and Nectarine produce fruit on the growth of the previous season; consequently the bearing wood of this season must be replaced by young growth for the next, retaining a shoot at the base of the bearing shoot, and another at its extremity. The growth above the fruit should be stopped when a few inches long unless required for extension. Shoots must also be retained upon trees extending at about 15 inches apart, and those for forming the branches should be trained at similar distances. If aphides appear apply an insecticide, tobacco juice diluted with six times the quantity of water being efficacious, and should be employed as early in the afternoon as to allow the foliage to become dry before night, especially if there is a prospect of frost. If mildew appear apply flowers of sulphur to the parts affected. Keep a strict look-out for the Gooseberry caterpillar, and upon its first appearance dust the bushes with fresh hellebore powder. Mulch plantations of Strawberries with littery manure, to allow time for its being washed by rains so as to form a clean bed for the fruit. Chopped straw forms one of the best materials for mulching Strawberries, and is disliked by slugs.

#### FRUIT HOUSES.

**Peaches and Nectarines.**—Complete disbudding in the latest houses, being careful not to allow more growths than will be necessary to supply the bearing wood of next year, and to continue the extension or furnishing of the trees. Many failures in Peach culture are caused by overcrowding the foliage. The shoots may be 15 inches apart, and the branches 12 to 15 inches distance from each other. If the extension system is practised the distance may be increased with advantage. Very fine fruits result from this mode of treatment, but it is no use attempting it unless space be allowed the foliage to insure the thorough ripening of the wood. Any shoots outgrowing the limits assigned the trees should be stopped, and the laterals be pinched at the first joint. Carefully tie-in the shoots at the base, and pinch out the point of those retained to attract the sap to the fruit. Thin the fruit in good time, removing the smallest and worst placed. See that there is not any deficiency of moisture in the inside borders.

Syringing must be attended to twice a day in fine weather. In succession houses attend to tying-in the shoots, pinching laterals, watering and mulching inside borders, affording liquid manure to trees that are not very vigorous and which are carrying heavy crops. With the fruit ripening maintain a dry condition as regards the trees, and preserve a somewhat dry condition of the atmosphere by a free circulation of air; but do not allow the trees to suffer through insufficiency of water at the roots, or it may prejudicially affect the ripening of the fruit and the maturation of the buds for another year. The fruit on trees started early in the year has passed the stoning process, and is now swelling. Continue syringing until ripening commences, when it must be discontinued; but the border may be damped and mulched with short manure. If it is desired to accelerate the ripening of the fruit the temperature may be maintained at 65° to 70° or 75° by artificial means, and 80° to 85° or 90° from sun heat.

*Pines*.—Careful attention is necessary with fruiting plants at this time of year owing to the variableness of the weather, which necessitates the maintenance of a moderately high and moist atmosphere for plants with the fruit in an advanced condition of growth. This renders them more susceptible of injury by scorching if the ventilation is not carefully attended to. Examine the plants weekly, and when any are in need of water afford it liberally. Periodical waterings are not to be commended; the judicious application of tepid liquid manure or guano water is, however, useful. Plants where bottom heat is from fermenting materials will not require water so frequently as those where the heat is supplied by hot-water pipes. Admit air at the top of the house at 80°, the temperature ranging through the day from 80° to 90°, allowing a rise of 5° more after closing the house at 85°, with moderate ventilation; but if it be desirable to enlarge the crowns close with 5° more. Keep the heat regular at the roots at 80° to 90°, having resort to fire heat only to prevent the temperature falling below 70° at night and 75° by day. Syringe the plants about every other day, or less frequently according to the weather. Continue former instructions with respect of other stock.

#### FLOWER GARDEN.

Lawns require frequent attention in mowing, rolling, and sweeping. As the grass grows freely early in the season, frequent mowing may be practised to give the turf a close bottom. Coarse weeds are often so conspicuous as to disfigure the lawn, Daisies being most troublesome. Grub them up by the roots, and should this cause any bareness in the turf a little fine soil can be employed as a top-dressing. Sowing seeds of some fine Grasses, such as *Cynosurus cristatus*, *Festuca duriuscula* and *F. tenuifolia*, with Suckling Clover, about 4 lbs. each per acre, will soon improve the appearance, rolling the lawn well. Grass edgings should be cut with the knife, rolling before doing so after rain, which facilitates the cutting and gives a sharp well-defined edge. Remove weeds from gravel walks. Any walks having a discoloured surface or containing many small weeds may be broken up to a depth of about an inch, and have the surface raked occasionally during dry weather. After eradicating the weeds carefully rake the surface, and after rain roll it down. Transplanting Hollies and most choice evergreens may safely be performed this month, being careful to remove them with as many fibres as possible. Firm the soil well about them, and give a good watering after the roots are covered to settle the soil about them before finally filling up, and if the weather is dry a slight syringing will be of great benefit to them. A mulching of leaf soil will also be advisable, or a couple of inches depth of loose soil on the top is better than too close a surface. Hollies that are not so symmetrical as desirable may now be cut in.

Roses in most cases were greatly injured by the severe frosts of winter, but are breaking strongly. The cold weather has greatly retarded the growth, and aphides are appearing. Tobacco water has no equal for destroying aphides: a gallon of tobacco juice will make seven or eight gallons of liquid sufficiently strong for the purpose. Tobacco powder is efficacious, especially if applied on a dewy morning.

*Bedding Plants*.—It will be necessary to transfer these to frames and other temporary places in order to gradually harden them. Many of the hardier varieties may be placed near walls or in other sheltered

places where they can receive temporary protection in case of frost. Coleuses, Iresines, Alternantheras, and other tender plants will require the protection of glass some time longer. These with Lobelias, Verbenas, and Heliotropes can be planted out in the refuse of old Mushroom-beds, pits, or frames, in which they will grow strongly and not require nearly so much attention as plants in pots or pans. Asters, Stocks, Marigolds, and Zinnias may be sown now in light rich soil in cold frames kept close until the plants appear, then admitting air freely and watering as required. By the middle of June the plants will be ready to place out, and they succeed much better than those raised in heat.

#### PLANT HOUSES.

*Greenhouse*.—Tuberose may be placed on damp shelves to prevent them becoming dry, and at the same time lessen the necessity for giving water until they have made some growth. A little bottom heat is essential to secure root action. When growth has commenced remove the plants to a house or pit where they will have a temperature of 60° to 65°, supply watering liberally and keep them near the glass. Plants of *Richardia æthiopica* that have flowered through the winter may now be divided and planted out of doors in well manured beds. A position sheltered from winds is most suitable, and if temporary protection can be given in case of frost it will ensure the plants a good start. These can be lifted and potted at the end of September.

Cockscombs should be placed as near the glass as possible to insure dwarf habit. Sprinkle them to keep red spider in check, and do not allow the soil to become dry. Balsams need a light position and liberal treatment. The earliest plants may be supplied with liquid manure. Globe *Amaranthuses* requires to be kept cooler than Cockscombs, and to be more carefully watered. Show and Fancy *Pelargoniums* require liquid manure, especially for plants in small pots. Young plants of Zonal *Pelargoniums* intended for flowering after the show kinds are over should be potted if needful, stopping the shoots to ensure a branched habit; remove the trusses as they show, and when the pots are filled with roots supply weak liquid manure.

## THE BEE-KEEPER.

### BEES BUILDING IN THE OPEN AIR.

AT the close of an exceedingly interesting letter of Mr. Frank Benton, concluded in the last issue, and for which we are indebted to Mr. Neighbour, Mr. Benton apologises for *Apis dorsata* in these words—"We must not be prejudiced against the bees because they build their combs in the open air. Our yellow bee does the same thing in tropical countries, and when unable to find a suitable place to settle." I am glad to be able to corroborate Mr. Benton by an instance of this, the evidence of which still exists.

In the beginning of September, 1874, the Hon. and Rev. H. Bligh discovered a colony of *Apis mellifica* (our common bee) in a Privet bush near Henley. That the insects had been at least some weeks established was certain, for not only had a large quantity of worker comb been built, but in a good patch of drone comb the cells were stained by the exuviae of the males that had already left them, while a second set of grubs were far advanced. Since twenty-five days are occupied in maturing a drone from the egg, and eight or nine more would be required to bring the succeeding grubs to the condition in which they were found, we have but eight days left of our hypothetical six weeks for the bees to build much worker comb and then make preparation for colonising by turning their attention to the production of drones.

The handy work of this *al fresco* family was secured by cutting through the stems of Privet and removing the combs bodily, which was in no way difficult, as the whole of them had been tied together by interlacing twigs. I was honoured by having this specimen presented to me by the aforesaid gentleman who discovered it, and a few times since it has been used at lectures or lent to grace collections of curiosities, and has in consequence suffered after the fashion of the Temple Bar Memorial—going in parts to the cabinets of the curious, or rather, perhaps, suffering under the thumb of the destructive; but enough remains to bear testimony to Mr. Benton's statement. The leaves would appear to have been carved from the petiole by the clever bees "that nobody owned,"

they securing thus room for their combs and many points to which to fix them, so that the wind would not disturb their arrangements.

On one occasion here we found a cast that had started building between a fence and an old and dense Black Currant bush, while many have no doubt seen combs built under floorboards or between skeps and the backs of the sheds containing them; but in these cases the breeding chamber was under the hive roof, while the combs built outside would only be used for store until room could be found within, when every scrap would be removed into secure quarters. Bees occasionally display very singular power in adapting themselves to new circumstances, and it is impossible to say how far these bees might have covered themselves above had they been left undisturbed. Some few years ago, when I used from five to seven slots of wood as a cover in the position now taken by the quilt, one of these slots was by accident omitted. Two or three days after the bees had nearly completed a roof for themselves, made by adding wax and propolis at the edges of the exposed frames. These additions stretching towards each other had actually in places met. In transferring it is not uncommon to find doors narrowed and windows covered by partitions or curtains of propolis, and an extension of this instinct might have done a good deal towards saving these bees in the Privet bush from rain, if not indeed from frost and snow.—FRANK R. CHESHIRE.

## CALENDAR OF OPERATIONS IN THE APIARY.

### MAY.

THE labours of the attentive bee-keeper are this month beginning to show results. Colonies of four or five frames at the end of March should now have from eight to ten Woodbury frames of brood or their equivalent, and be crowding their hives from end to end. We must now determine whether we will endeavour to prevent swarming and accept surplus in its place, or whether swarm and super shall be our ideal. If the latter, we select our best colony, the bees of which present the characteristics we most value, and remove its queen in some manner that does not seriously thin the population of the stock in order that it may produce us a number of highly nourished young queens. The methods of doing this admit of numberless variations—e.g., we may take the queen and insert her in some queenless stock; or we may make a swarm of the queen and the whole of the colony, and place the hive, combs, and brood upon the stand of one of our strongest stocks to be repopled by its flying bees; or we may, without displacing the queen at all, give combs of her eggs to queenless stocks.

If the bees always produced their queens from eggs laid just before the removal of the mother sixteen days would elapse before the young queen would gnaw out, but frequently this happens on the twelfth day, when the first queen hatching would destroy the rest. We must therefore (if we would secure the immense advantage of giving ripe queen cells) on the tenth or eleventh day after one of the operations indicated swarm other colonies artificially, and insert the ripe queen cells now at command in the swarmed hives. The queen will quickly be out, and in nine days more should commence laying. We in this manner reduce the time the bees would naturally be without a queen by at least a week—a gain probably of ten thousand bees. We according to this plan made an artificial swarm on Saturday, and on Tuesday week we should make other swarms to give places for the queen cells then to be ready for insertion. In making the first swarm it is wise not only to reduce the entrance, but to reduce the amount of brood by distributing any combs of larvae which seem to give more work than the residue can accomplish. This may not always be necessary.

Where skeps are found with frame hives secure queen cells in one of the latter by any plan, and when these are getting near hatching drive swarms from the skeps, set them on the old stands, and insert the queen cells either in the feed hole, or fix them up between the combs by simply pushing the combs a little from each other to make way for them, when they will be sufficiently grasped to be retained in position. The bees will fix them, but after hatching they had better be removed. Cut the queen cells out with fully a square inch of comb attached, and be very careful not to pinch them. Do not be over-anxious about early swarming; excessive haste here hinders more than any other mistake bee-keepers commonly make.

Feed the swarms regularly, even in good weather. If they have foundation you may feed quickly if you like, as no undue amount of drone comb can be built. If no foundation is used feed slowly, and at night only. In using foundation with swarms fix with wax at the top, as well as using Cheshire's foundation fixers.

Supers or sections, if swarming is to be avoided, may be put on whenever bees fill the hive and honey is coming in freely. When this is done all sealed store combs had better be removed, which either gives space for placing sections in a frame to be hung in the hive body, or admits of decreasing the hive space by a tight-fitting dummy, and so by giving the bees less room below, the more surely driving them into the super. Cover the super warmly. Nothing pays better than well-made super or section covers, of which the teapot cozy is the type. An irregular rag of carpet, even if sufficiently

aesthetic for the tea table, would not keep the pot warm. In unfavourable weather feed with constancy and care, and then swarms will do as well as if we were in Madeira.

Nuclei can now be started with advantage. The best form for these seems to be a couple of ordinary frames of brood—some of it hatching and covered with bees—placed in a hive, duly contracted of course. In taking these frames from the stock be very careful that the queen is left behind. The nuclei may be made the day before the queen cells are ready for excision. At the close of the day on which they are made take a peep at them, and should they seem bare of bees shake the bees from a frame taken from the hive which provided the nucleus on to a board placed at their door. Most of the bees will run in, and all but the oldest will remain. After the queen, hatched from the given cell, has mated and has commenced ovipositing you will either build up the nucleus into a stock or remove the queen. By attentively supplying eggs and grubs whenever the little colony is able to undertake the care of them it may be made to supply several queens in succession, and yet be constantly growing in strength so as to pass into the winter as a fine stock.

So much for fine-weather work, which should also include all the preparation which foresight can suggest in the way of sections, supers, and additional hive accommodation; but success, if success means profit, largely may depend upon painstaking feeding in bad May weather, of which we generally have a share. Just when cold drizzle or sleet makes outdoor work unwelcome the bees must be fed. Neglect after a bad day when gathering has been suspended causes the devouring of thousands of eggs, and this means thousands less of gatherers when the later glut comes. As money makes money so sugar makes honey. Let us keep up artificially if we cannot get naturally an uninterrupted course of grub-raising, and even a short honey glut will not leave us without results. One of the very best accounts a man had ever to give of a swarm relates to one of mine that passed through a May more cold and wet than any that I remember; but I loved my bees, and they were not ungrateful.—F. CHESHIRE, *Avenue House, Acton, W.*

## TRADE CATALOGUES RECEIVED.

Cranston's Nursery and Seed Company, King's Acre, near Hereford.  
—*Catalogue of New Roses.*  
Ewing & Company, Eaton near Norwich.—*List of New Roses.*  
Francis and Arthur Diekson & Sons, The Upton Nurseries, Chester.  
—*Catalogue of Bedding Plants and New Roses.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Camellia Unhealthy** (O. G. R.).—Your plant is much infested with either scale or mealy bug, or both. It is impossible for any plant to thrive with the foliage in such a dirty state. There is only one mode of cleansing such leaves as those you have sent, and that is by sponging them carefully with warm soapy water. This you appear to have done, but the sponging has not been sufficiently thorough or sufficiently frequent. After you have once cleansed the foliage you may do much to keep it clean by adopting the mode recommended to another correspondent for the prevention of mildew and insects on Roses. Your plants have been much neglected, and as you have had them two years we presume you have not had time to give them the attention they have needed.

**Mildew on Roses** (A. A.).—Your Roses appear to be attacked with the orange fungus, which has also spread to the Ferns. It is not easy to extirpate. Syringing with a solution made by dissolving 2 ozs. of soft soap in a gallon of water and dusting the affected parts when wet with flowers of sulphur will, if persisted in, probably prove beneficial. The house must be well ventilated. Mr. Bardney, who grows Tea Roses extensively, keeps their foliage and also that of fruit trees under glass perfectly free from mildew and insects by the plan that was described as follows in our columns last year:—"About 2 lbs. of soft soap are placed in a saucepan with a little water, and boiled for about twenty minutes. This is mixed with five or six gallons of water and kept in a large flower pot. Half a pint of the solution is placed in a large waterpot full of water used for syringing. Neither insects nor mildew appear able to exist on the foliage, while nothing can exceed the admirable condition of the trees and Roses. It is important that it be used regularly—that is, whenever the syringe is employed."

**Exhibiting Pansies** (L. J. K.).—We are not aware that the boxes can be had "ready made." It is not usual for seedsmen or florists to keep them in stock. Any intelligent carpenter can make them, and a brazier can supply the

tubes for holding water to support the flowers. Half-inch deal is stout enough for small boxes to hold a dozen flowers, but if the boxes are larger the wood is better a little stouter. They should be painted green. The boxes, unless otherwise stipulated by the authorities of the show, may be 5 inches high at the back, 3 inches in front, and 18 inches wide, with holes for the tubes not less than 2½ inches apart.

**Extirpating Ants (C. M. K.).**—They are most difficult to destroy or drive from their haunts. They do not like guano sprinkled in their runs, nor paraffin. If half-picked bones are laid in the runs they will speedily be covered with the insects, and by plunging them in boiling water they are mercifully killed. A sponge partially saturated with treacle has the same effect in attracting them. Camphor dissolved in water and poured in their haunts makes them uncomfortable, and carbolic acid diluted with twelve times its weight of water and sprinkled in their haunts is said to drive them away. Cotton wool wrapped round the stems of Peach trees and kept moist with tar prevents the ants ascending. They sometimes eat off the stamens of the flowers, and also attack the ripe fruit, but otherwise do not do injury unless they make their nests in flower pots. They mostly abound where insects are present, and you will find it very advantageous to permit no aphides or other insects to congregate on the plants or trees in your houses. You may sow the Mangold Wurtzel seed in drills 2 feet apart, and cover the seed an inch deep. A mixture of 5 cwt. of guano and 2 cwt. of common salt per acre is a good manure for this crop on moist soils.

**Cyclamens not Thriving (A Brixton Amateur).**—The root-action is defective, caused probably either by watering excessively or insufficiently; or the plants may have been placed in a too cold, dry, and draughty house during the winter. As they have made no leaves you will have a difficulty in restoring the health of the plants. As soon as weather permits turn them out of the pots, removing a good portion of the old soil, and plant them out in your garden, watering them as needful during dry weather, and if leaves are formed take up and pot the plants in early autumn. To insure a stock of healthy Cyclamens it is desirable to sow some seed yearly, as the plants as they get old are prone to disease and deterioration.

**Sowing Stocks and Asters (Alaric).**—It is not too late for sowing seeds of these. If you can spread 3 inches of very much decayed manure in a frame, or even a sheltered border, covering it with an inch or two of soil, and sow the seeds thinly in drills, you will be surprised how rapidly the plants will grow if they are watered as needed, with tepid water if possible. In all probability the plants thus raised will be finer before the summer is over than those that were raised in heat in March, and which, as you say, are now "tall, thin, and weakly."

**Cucumbers not Growing (Puddle).**—Your plants have received a check of some kind, it may have been by a too low temperature or insufficient atmospheric moisture, or it may have been the other extreme—too much bottom heat, which has injured the roots. You afford no details whatever either as to the temperature or treatment to which the plants have been subjected. With bottom heat of about 80° and a minimum night temperature in the house of 65°, increasing by day to 70° without sun and 85° with sun, with atmospheric moisture in proportion with the heat, the plants ought to grow freely if the soil is suitable and the foliage kept free from insects. Rough turfy loam with a third of leaf soil and wood ashes added will be suitable for planting in. You had better syringe the plants with a weak solution of soft soap and tobacco water, or after syringing with pure water dust the foliage with tobacco powder. If, however, the plants are much infested with insects you will not find it easy to cleanse them.

**Amaryllises not Flowering (Idm).**—They are stove plants, and very few of those succeed in an ordinary greenhouse temperature. Your plants have also in all probability been much overpotted. Unless the pots are crowded with roots you cannot expect the plants to flower well; they, however, really require more heat than the greenhouse affords. Shelves in the Cucumber house would be a more suitable position for them. Your proposed treatment of the Strawberries is correct.

**Garden Plans (R. P. Skipton).**—You afford us no guide whatever to enable us to decide on the number you require. Without having particulars as to the size of your lawn and an outline of your requirements, we might cause you disappointment instead of render you assistance. If you will write to us more fully and send stamps for as many numbers as you would like to have, we will endeavour to aid you. All the back numbers are not in print; those that are can be had for 3½d. each.

**Cordon Pears (F. J.).**—Begin pinching as soon as the shoots are from 3 to 6 inches long, leaving from two to five leaves according to the condition of the shoots. We cannot be more explicit as to the number of leaves, because there is a considerable difference in the habit of growth of Pears, some being coarse and long-jointed while others are compact and short-jointed. Do not attempt to confine the pinching to any particular part of the stem, for the lateral growth does not grow equally fast. Some shoots are always first; pinch these, and do others as they become long and stout enough, and so let the process be so gradual as not to check the entire growth at the same time. This pinching may be continued till the end of July in the south, but it must be discontinued proportionately sooner northwards. As a general rule pinch the midsummer growth once, and then let all subsequent growth alone till the leaves fall. Late pinching only induces an abortive weakly growth from buds that should rest dormant for a strong spring growth. Nip off the end of the leading shoot when it is a foot or 18 inches long, and you will thus secure a second growth of equal length annually till the top of the wall is reached.

**Raising Pansies (E. James).**—As all your Pansies are good you may, by saving seed from them, expect to obtain some good varieties, although a great number will be inferior to the parents. Where artificial fertilisation is resorted to it is advisable to exclude bees and other insects; but if you have not had experience in this delicate operation you had better allow the plants to seed naturally, not allowing an inferior variety to flower in your bed. It will not be well to allow many pods to ripen on each plant; one or two will be better than more, as then the seed will not only be finer but the plants will not be exhausted, as they must be by maturing a heavy crop. Rather strong soil with gritty matter incorporated and enriched with decayed manure, preferably cowdung, will be suitable, planting rather deeply. Show Auriculas need the protection of glass; many of the Alpines succeed in the open ground, the site being well drained.

**New Cucumber (W. Wells).**—If you desire to submit fruits of your Cucumber to the Fruit and Vegetable Committee of the Royal Horticultural Society you must send them direct to South Kensington in time for one of the meetings. We do not convey specimens of any kind that are sent to this office

to any exhibitions. You can obtain all necessary particulars for exhibiting fruits by writing to Mr. Barron, Royal Horticultural Society's Garden, Chiswick, London. The fruits you have sent are very good, and the variety is doubtless a very useful one; but whether it is distinct from all others we leave the Committee referred to, to determine when specimens are placed before them.

**Summer-pruning Pear Trees (D. E. F., Bradford).**—We cannot better reply to your questions than by publishing the following remarks by an excellent gardener and successful cultivator of hardy fruits:—"Summer pruning is the most important operation of fruit-tree culture; for it is evident that if the laterals are not shortened the crop must be small from the vigour of the tree being expended on a quantity of spray, and the fruit must be badly coloured and ripened from its being shaded by the needless crowding of the foliage. It is not the present production only, but the crops of succeeding years that are injured by neglecting to summer-prune; for the crowding of the shoots and foliage prevents the spurs receiving sufficient light and air for their full maturation and perfection. Summer pruning has for its object the maintaining of the tree in order and fertility; it tends to check overluxuriance, prevents the overcrowding of the shoots, secures the formation and perfection of the spurs and fruit-buds, and favours a more full perfection of the fruit. There is not only some difference of opinion as to the time, but also as to the amount of summer pruning. The time is solely dependant on the season and the vigour of the trees. The amount of pruning depends on the growth of the trees operated on, for that of some trees is so weak that it may be necessary to encourage it; others are not weak in growth, but are vigorous enough to produce fine fruit; whilst some are so vigorous that the spurs are not nearly so plentiful as the shoots, and the fruit fewer in number than the spurs. Now, to fix any time as the most suitable for summer pruning, and to limit the extent of the pruning to any one rule is impracticable, as it is evident that different trees require different treatment. All shoots and laterals not required for the extension of the tree, or to fill up vacant space, must be summer-pruned or pinched, whether they spring from the young or old wood; but the leading shoots, or those shoots required for the extension of the tree, should not be pruned, except in the case of pyramidal or bush trees, in which, when the leading shoots make a greater growth than 18 inches, these may have their points pinched at that length. If the trees have covered as much space as is allotted to them, then the leading shoot, and, in fact, all the shoots, should be stopped or pruned in the same manner as the laterals. Trees that are moderately vigorous, or those with shoots not exceeding from 9 to 12 inches in length, should not be pruned until the fourth week in June or first week in July, according to the season, when they should have the points of all the laterals taken out at the sixth leaf, and when they push again, as in all probability they will, take out their points at the third joint above the last stopping, or from the base of the last growth. Trees that are vigorous, and make shoots when unrestrained of 15 or 18 inches in length, should have the points of the shoots taken off above the fifth leaf, and all growths after the first stopping should be pinched off at the third leaf until the beginning of September, when pinching should cease. Trees of very strong and rampant growth should be stopped as soon as they have made four leaves, and repeatedly throughout the summer up to September at the third leaf, after the first stopping. Trees upon the Quince stock may be stopped in all cases one or two joints closer than those on the Pear. The most vigorous shoots will be those at the top of the trees, or where the greatest amount of winter pruning is practised; but, wherever they are, the strongest shoots will of course attain a length fit for pinching sooner, and they ought to be the first stopped or pinched, and in the course of a few days the remaining shoots should be stopped. In all cases, in calculating the number of leaves for stopping, do not count the latent or undeveloped buds at the base of the shoots, of which there are always two or more; only the leaves should be counted, and not the joints or buds. Any trees with the branches weaker in one part than in another may have the laterals upon the strong branches closely pinched, whilst those upon the weak branches are allowed to grow without stopping until September, when a few inches may be cut from the extremities of each, and these in winter should be cut back to within an inch of their base. In spring a number of shoots will spring from the short stub left. All of them except one should be pinched, that one being left to grow unrestrained until September, when a few inches of its point may be removed, and cut close away at the winter pruning. The shoots pinched throughout the summer should be cut in winter to within 1 inch of their base. We have now a stub two years old, on which fruit-buds are usually produced. It is hardly necessary to add that the short stubby shoots (spurs), with a bunch of leaves, are not to be stopped, for on them fruit-buds form."

**Extension-trained Fruit Trees (Practice).**—We have received your communication, but it is necessary that we be informed of the name and address of the writer before the propriety of publishing the letter is considered.

**Names of Plants (A. T.).**—The specimen with small leaves is Diosma ericoides, the other was insufficient. (W. D. H.).—*Mercurialis perennis*. (W. H. W.).—1, *Lapageria rosea*; 2, *Pittonia Verschaffeltii*; 3, *Fuchsia splendens*; 4 and 5, insufficient; 6, *Cissus discolor*. (G. O. S.).—*Narcissus Jonquilla*. (T. S.).—1, *Omphalodes verna*; 2, *Dielytra eximia*; 3, *Ranunculus amplexicaulis*; 4, Very much crushed, but resembled *Atropa Belladonna*. (J. P. T.).—*Pyrus amygdaliformis*. (L. L. D.).—1, *Caltha palustris*; 2, *Aubrietia Campbellsii*; 3, *Alyssum saxatile*; 4, *Trollius asiaticus*.

**Bees—Various (Buzz).**—1. Bed-ticking is too expensive to use under the quilt. Common calico lasts a season, and renewed in the spring keeps fairly clean till the autumn. Haircloth is practicably indestructible, but expensive, while it is too stiff to settle down well over the hive, and will not fit itself over flour-cake as calico does. 2. Plum bloom yields honey, but bees seem to prefer Cherry to it. If the latter abounds the former is less visited. 3. Bees generally gather honey and pollen at the same time. With some plants, however, this is impossible, Catmint by example; but these matters can only be fully explained at considerable length. We are contemplating an article in relation to it. Young bees take an airing a time or two before gathering anything. Where brood is being fed much water is carried (especially with an east wind) if the air be only warm enough. 4. We never hesitate to open a hive if any object is to be served. We have had every comb out of a hive for thorough examination five or six times daily for three weeks in succession, and even this did not, as we think, hinder the bees to any serious extent, while injury there was none. They get quite to understand the handling as regular, and offer no expostulation. 5. Yes, 50° Fahr. in the shade is warm enough if the air be fairly still. 6. It is not well to interfere too much with the brood of any hive, but often a queen may not have sufficient bees to cover all the eggs she could lay, in which case she could spare a comb of eggs without loss, as an empty comb in its stead would quickly be refilled. The eggs given to bees raising a queen would do them good every way. It is in this manner we keep our nuclei, engaged in raising queens, strong. They are practically queenless constantly, but eggs given them in exchange for empty combs bring them into condition to form colonies as soon as their work of queen-raising is at an end.

## COVENT GARDEN MARKET.—MAY 11.

TRADE more lively, with good supplies of indoor fruit quite sufficient for the demand.

## POULTRY AND PIGEON CHRONICLE.

## AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 367.)

AMONG patent haymakers Howard's deserve notice, as for many years these machines have required no alteration in their construction. The wire screen, however, to prevent the grass lodging on the gear has made this implement complete. Like all other well-devised labour-saving machines this one is of great importance, especially in the expedition of the work. Any implement like this which is calculated to shorten the hay-making period is of great advantage; and in many cases, and especially in certain catching seasons, its use in a single year will more than repay the cost of the implement. In the construction of this machine the forked barrels are so arranged as to render clogging almost impossible. The forks are mounted in sets of three and placed in a zigzag position, an arrangement which equalises the work and thoroughly separates and distributes the crop. The gear work is both strong and simple, and by a simple eccentric movement of the main axle the rakes can be quickly changed from the forward to the backward action. A similar movement is also used for raising or lowering the fork barrels. When, however, it is once set for the forward movement no change is required to use the machine with the backward action, except the reversal just described.

The same firm has a patent self-acting horse rake, which is constructed upon the simple brake principle, and is easily managed. The arrangement for supplying the load is extremely simple, the driver, if riding, merely having to touch a lever with his foot, and, if walking, simply to take hold of a lever with his hand. In consequence of the demand lately sprung up for rakes of a larger capacity, as well as with higher wheels, such are now made if required.

Owing to the reluctance of farm labourers to effect any of the heavy work, such as mowing, and the bad work often made when it is done, it becomes imperative to use mowing machines. The "Wood" mower deserves notice. The main frame of the implement is constructed of cast iron, and is both rigid and compact.

Its strength, simplicity, and durability have been proved during the past ten years, during which time it has undergone little or no material alteration. These machines are drawn by two horses, and with strong animals, such as we have continually recommended for use in these columns, a good half day's work can be done in a satisfactory manner. A change of horses, so that each pair may do six hours' work, is specially necessary, in order that now the days are long a large amount of work may be done. The only difficulty now is in the case of water meadows, where mostly the grass can only be cut with the scythe in consequence of the numerous trenches. In some of the catch meadows, however, the mowers can be used, because the narrow and shallow trenches for catching and spreading the water offer no impediment to the working of the machine as compared with the deep and deviating carriers in the flood meadows. The "enclosed gear mower" has various new features peculiar to itself, all the gearing being covered and protected from dust and dirt. There is also no gearing in the wheels encased in the frame. The wheels are 31 inches high, with longitudinal and centre rod-ribs, and will consequently travel on the road as smoothly as a cart. The new one-horse mower is constructed upon the same principle as the last-named, and as only one horse is required to work it its use will be a great advantage on small occupations, or for park-lands where but few horses are kept.

## WORK ON THE HOME FARM.

*Horse Labour.*—Work on the fallows for roots will still be required, especially on those farms cultivated upon the four-course rotation, for in that case the Wheat will be sown for the most part after Clover lea, which has been generally rather foul with Couch or Water Grass in consequence of the succession of untoward seasons for several years past, and when the root crops succeed Wheat out of lea the fallows always need much work, even in a favourable spring. In some cases, however, the Mangold seed is not all drilled, nor Carrot seed either; but the sooner they are sown the better. Our earliest-sown Mangold seed germinated well, and the young plants have produced second leaves with great regularity. The seed was drilled on the 12th of April, the land having been liberally dressed with yard manure, besides artificial manures applied in drilling. Some farmers object to sowing so early, as they think many of the roots will produce seed stems; but when that happens we cut off the stem close to the crown of the bulb, after which the roots will advance nearly as well as the other plants. This is a favourable time for planting Cabbages or Thousand-headed Kale; it is, however, a slow process if planted by hand, and where the plants are large enough we lay them along the furrow and plough them in with the one-horse implement by turning a furrow over on them, the horse walking out of the furrow. A man should follow with a small hoe, and place a little soil over those which are exposed, and release any plants entirely buried; in this way they may be planted in the driest weather without injury; the only difficulty we have experienced is caused by rooks pulling up the plants.

*Hand Labour.*—Men and women may be employed on a rainy day in the manure house breaking, mixing, and preparing artificial manures in readiness for drilling with seeds; also the ashes should be broken down and screened, for when they are kept in the manure house they will always be dry and ready for use. We recommend the home farmer to look out for a roomy building to store manure in, and nothing answers the purpose better than a barn mow after being floored with prepared chalk or concrete. Men will soon be required to cut the grass round the hedges and fields upon all dry land, and this growth is often composed of wild Parsley and Hogweed, which may be cut twice a year—in May and July—and thus keep the hedges and borders clean, and prevent weeds from seeding. At the same time we find, on dry soils especially, very early fodder available in this way for young stock and breeding sows in the yards. We have often found our young fattening cattle do even better upon such green food than upon the best Clover, and they eat it in preference. A farmer occupying an enclosed district annually feeds twenty dairy cows entirely upon such border and coarse hedge growth, giving them also 4 lbs. of cake each per day, and he obtains a large yield of milk of good quality, though it would probably affect the butter. To make the most of his banks and borders, as well as hedges, he keeps them all closely trimmed, so that the young wood, even Brambles whilst young, furnish food or manure. Another farmer cuts all the Sedge-like and coarse grass in the water meadows into chaff, mixed with clean Barley or Oat straw, to feed either young stock in yards or dairy cows at the stalls at milking time.

*Live Stock.*—The sheep on the hill farms where breeding flocks are kept have lately been doing well in the water meadows at daytime and folding on Rye at night time. The lambs fare worse, unless Mangolds have been reserved for them; in which case, if the cut

roots are mixed with bean, barley, or cake meal, the lambs will thrive extremely well. After the Rye as a night fold is gone Trifolium or Vetches will do, but at daytime folding on Giant Saintfoin will help them. Italian Rye Grass must not be forgotten, because it ought always to be at hand, like Mangold, to prevent scarcity in late springs or very dry summers until the 21st of June, when it is usually ploughed in and the land pressed and drilled with Red Mammoth Turnips or Rape. On the corn-growing farms and where Potatoes are cultivated there is no room for sheep in the summer months, so they will all be sold as fast as shorn. Ewes and lambs should be sold fat together, or nearly so; for on such farms we hold to the policy of growing and reserving food for sheep in the summer, and feed it in the winter and early spring months: except that, instead of risking the whole of our Clovers for hay, we like to cut some of it several times and feed cattle with it in their boxes, with cake and some Mangold also if it can be saved.

#### MALT SPROUTS.

THE amount of nitrogen and phosphoric acid in malt sprouts render them not only valuable as a food, but also as a fertiliser when applied to crops. Whether they can be economically used as a fertiliser depends upon the price at which they can be obtained. If used for cattle food they should be scalded before being fed. They are very light and dry when sold, and will absorb a large quantity of water. Boiling water not only renders them more digestible, but it makes them a safer food. If fed dry they are apt to swell in the animal's stomach and produce hoove. They are obtained from Barley when made into malt. In this process the Barley is put into a large tank to soak for two or three days, or till it has soaked about half its own weight in water, it is then spread about a foot thick upon a floor, when germination takes place. This process is continued till the plumule, or that shoot which is destined for the future stalk which runs under the husk, reaches the other end of the grain, while the radicle, or that which has to form the future root, grows right from the grain; at this stage further growth is stopped by expelling the water upon the drying-kiln. It is then screened, which removes what is termed the radicle, the product being termed malt sprouts. In England, where they are considered a valuable food, they are known as malt combs. They are more valuable when properly prepared than brewers' grain, but it costs both labour and fuel to put them into so digestible a condition as the brewers' grains. They contain, however, more nitrogen, say about  $4\frac{1}{2}$  per cent., in their dry state, but when soaked with water to the same extent as grain they contain very little if any more. Of phosphoric acid they contain 2 per cent. and  $2\frac{1}{2}$  per cent. of fat, and when obtained from the maltster they contain but 8 per cent. of moisture. This gives them a great advantage in hauling over brewers' grains, which, as they are received from the brewers, will contain 80 per cent. or thereabouts of water. The sprouts contain in a dry state 45 per cent. of starch and sugar; brewers' grains if as dry as malt sprouts would contain in all probability as large a percentage of starch as the sprouts contain of sugar and starch, but a considerable part of the starch in the grains is converted into sugar by the fermentation which the grains undergo after they are brought from the brewery.—(*American Cultivator.*)

#### VARIETIES.

**PHEASANT AND POULTRY MEAL.**—We have received samples of the Pheasant food, poultry meal, and tonic prepared by the Royal Norfolk Pheasant and Poultry Food Company. The meals appear to be well ground and blended, and the tonic is intended to provide in a convenient form the amount of stimulant necessary to carry the young birds over the critical periods in their growth.

— **BETTER THAN RENT REDUCTIONS.**—The difficulty which land-owners and their agents now experience in the letting of vacant farms, especially where such happen to consist of heavy arable land, should lead them to do all in their power to encourage tenants to lay down such to pasture. In many cases the tenants would be quite willing to do this provided the seed were found; and a better investment of money cannot be made by the owner. A discount of 10 per cent. is an immediate advantage to a needy tenant; but an outlay of 15 or 20 per cent. upon permanent pastures, warm cattle sheds, liquid manure tanks, drainage, &c., will prove a lasting boon to the occupier, and a future source of greatly increased value to the land-owner.—(*Journal of Forestry.*)

— **"THE PRACTICAL FISHERMAN."**—A beautiful volume under the above title, written by J. H. Keene, and published at the Bazaar

office, has been sent to us. It is admirably printed and well illustrated, and will no doubt be welcomed by all who are interested in the subject on which it treats. The author has evidently endeavoured to render the book as complete as possible, and we do not quite agree with him, as stated in the preface, that it is a "crude attempt" to supply a deficiency in literature of this kind; it is to our mind the reverse of crude, as besides giving detailed instruction to guide the inexperienced angler, much information is supplied relative to the history and habits of the several kinds of fish. The researches of other writers on the subject are embodied in the book, not as is stated "by paraphrasing their writings without direct acknowledgment," but by quoting them in a manner which is highly commendable.

— **THE WHEAT CROP IN THE UNITED STATES.**—A recent telegram announces that despatches to the *Chicago Times* from all sections of the North-west show that the spring Wheat is in excellent condition. The principal spring Wheat regions are Minnesota, Nebraska, and Dakota. All show increased acreage and unusually promising prospects. The season is several weeks later than usual, but the warm weather and the rains are pushing the crop ahead. Minnesota yielded over four million bushels last year, and Nebraska over two millions. The yield in both this year is estimated at 20 to 25 per cent. greater. More winter Wheat than ever before has been grown in all sections, and the prospect of an unusually large crop is good. The weather favourable everywhere.

— **LORD WAVENEY ON AGRICULTURAL DEPRESSION.**—Lord Waveney has addressed a letter to the Secretary of the Norfolk Chamber of Agriculture on the subject of agricultural depression. His lordship observes that the system of farming in England has been one of isolation under an appearance of independence. He considers that farmers require associations for obtaining a fixed supply of steam power for receiving into store for the purpose of resale the products of the farms of members, for advancing funds for the purchase of stock, and for dealing with salesmen in the great towns. Every process in cultivation must be abridged, and every barrier between the producer and the consumer, so far as may be, removed. Lord Waveney adds that he does not attach much importance to legislation, which at best is to warn rather than to instruct.

— **IRISH BUTTER.**—Complaints are occasionally heard of the quality of Irish butter, but the *Cork Herald* states that at the Melbourne International Exhibition that butter made in Ireland has again, as it did in Paris also, come off victorious. There were five orders of merit, and the first was given to Mr. T. T. Clanchy for butter which he sent out from Cork in December last. Our contemporary observes, it speaks highly for the quality of Cork butter that after crossing the tropics and being packed for six months this butter obtained the first award.

— **EPHING FOREST.**—The bye-laws made by the Conservators of Epping Forest have been allowed by the Duke of Connaught and Strathern (the ranger), and are now in force. Now the Corporation have this Forest entirely under their control they intend to make more satisfactory arrangements for keeping it in good order and preserving it from such injury as it has recently been subjected to. Only a few days ago 12 acres of brushwood were destroyed by fire, and other lawless acts have been committed. We trust the keepers will be more vigilant, and bring to justice any offenders who may be found damaging the Forest, which has been secured for the public at so much trouble and cost.—(*City Press.*)

#### PRACTICAL SCIENTIFIC BREEDING.

GENERAL PRINCIPLES.

(Continued from page 306.)

A KNOWLEDGE of the season of the year which is most advantageous for hatching is of primary importance in regard to the

production both of exhibition and of stock birds. The considerations affecting these are various, and differ in some points while agreeing in others. No general rules available for both sexes or for all the breeds can be given; but a broad line of distinction may be drawn between those breeds in which size is of primary importance and those in which it is not, and this will suffice for our purpose.

The large breeds, especially the Asiatics, take a long time to mature, and the cockerels take longer than the pullets. It is only by very early hatching that large size can be attained in the first year. The best known breeders of Brahmas, for example, take care to have a number of January chickens to select cockerels from, and even at the late shows cockerels hatched after March have very little chance. It is equally important for the breeding pen that the cockerels should be as matured as possible. It may therefore be laid down as a general rule that cockerels of the large breeds should be hatched as early as possible—certainly during the first three months of the year. As to the pullets the case is somewhat different. Not only do they naturally mature earlier, but it is also more difficult to retard the maturing process with them. Cockerels may be kept growing, but early-hatched pullets will insist upon laying some time in the autumn. This is a disadvantage in two ways. In the first place, a laying pullet soon loses condition and that bloom which is such an attraction; and in the second place, she probably will lay herself out before the eggs are required for the early hatching. Of course for the early shows early-hatched pullets as well as cockerels are a necessity, but the really important shows come late in the year; and for these, as also for providing eggs for early hatching, pullets hatched in March and April are best.

A great deal towards hastening or retarding the maturity of a bird may be done by judicious feeding. As to this we shall have a word or two to say later, but we may here refer to the other means usually adopted to retard maturity. The cockerels and pullets are in all cases separated when about two months old, and are kept not only separate but out of sight of each other. An old cock is sometimes put to run with the cockerels to keep them under and prevent squabbling, but unless he be well chosen and free from much tendency to bullying the youngsters, this sometimes does more harm than good. It is best that only cockerels of nearly the same age should run together, and the younger they are when first put together the less will be the chance of any quarrelling. A dozen cockerels in a moderate-sized run with an occasional change of run will do better than a larger number in an unlimited space.

The pullets are more easily managed in some respects, but the great difficulty with them is to retard their laying so long as to give them time to mature, and at the same time not to drive them into a moult or materially injure their laying qualities. Here, apart from feeding, the most successful method is to move them from run to run as they show signs of laying. Even with laying hens a move to a strange yard generally checks the laying for a few days, and the effect is more marked with pullets which have not laid. This must not be carried too far, or a moult may be brought on, and the bird thus rendered useless both for exhibition and early laying.

We may mention here that some exhibitors manage to attain great size the first year by moulting out their early hatched chickens before the great shows. Chickens as a rule only moult their chicken feathers gradually, and once they have attained their adult plumage retain it until their second year, when they of course have a regular moult. Asiatics grow a good deal at the time of their first regular moult, and by inducing a regular moult in the first year great size can be attained. This can only in the case of January-hatched chickens be done in time to get the birds moulted out for the great shows. They are allowed to mature tolerably early, and then by feeding and heat a moult is induced. It is risky work at best, and the birds lose in freshness what they gain in size, so that we prefer the other method.

Although for the purposes of the coming year late-hatched birds are of little use, still it must be remembered that Asiatics continue to grow, or rather make a new growth in their second year. We have known late-hatched cockerels which were apparently far too small and defective in colour turn out really fine birds after their first adult moult. Very late-hatched chickens sometimes retain a part of their chicken feathers, and thus appear defective in colour, which is apt to mislead beginners. If, therefore, chickens from some of the best birds cannot be got early enough to mature in the same year, it is well to hatch some later, and keep them over for use after their first adult moult.

Another matter as to which beginners require a word of caution is as to the relative importance of the earlier and later shows. A really promising bird should not be forced on to maturity to win

a prize or two early in the season at the sacrifice of his chances later on, and also to the detriment of his ultimate development. Birds thus forced on are almost invariably spoiled, and the experienced exhibitors only sacrifice their mediocre birds for the early shows, keeping the really good ones for the Palace and Birmingham, where the winning of a prize is of some account and not at once forgotten.

The breeds in which size is not regarded as of primary importance are more easily managed. As to these, the best plan as a rule is to hatch the chickens in March and April, when they are most easily reared and come in well for all the most important shows. Of course, those who desire to compete at the very early shows must have a few chickens before March; and where there is any special point which requires time for its complete development, such as the face of the Spanish birds, the early chickens have the best chance, but with these exceptions the March and April birds do best both for show purposes and the breeding pen.

Bantams require a special word or two. Here small size is an important matter, so that late hatching and early maturity are the points to be aimed at. April, May, and even June are the best months for the Bantams. They are in this way suitable for keeping with the larger breeds where variety is desired, as the hatching seasons do not to any extent clash with each other.

(To be continued.)

### TURKEY REARING.

WHEN the young Turkeys appear in the outer world do not lift up the old hen to see how many eggs have hatched, but restrain your desire to count your Turkeys, and let them alone for at least twenty-four hours. They will not require food during that time, and as they are very delicate when first hatched it is best to avoid handling until they get strong on their feet; then remove them with the mother hen to the coop and pen, which should be all ready for the occupants.

The coop must be of good size, slant-roofed, and tight enough to keep out rain. Where the ground is not wet, and the coop can be placed so that the rain will not wash under it, it will not be necessary to have a floor in the coop; but if you have any doubts about being able to keep the young Turkeys dry and comfortable during a rainy spell, you had better put in a board floor and cover with gravel or sand, which should be renewed as often as every other day. When the mother Turkey is left to herself she chooses a new resting place every night, and when you confine her in a coop you must imitate her example and give her a clean place by moving or cleaning the coop often.

Make a pen or yard in front of the coop by placing boards on edge and fastening them in position. This pen should be from 15 to 18 inches in height, and for a family of fifteen young Turkeys should enclose about 40 square feet.

When safe in their "house" and yard give the little Turkeys their first meal, which should be stale wheaten breadcrumbs soaked in milk, and hard-boiled eggs. Now when I say hard-boiled eggs, I mean eggs that have been boiled half an hour. Boil an egg five minutes and it will be tough and indigestible, but boil it half an hour and it will be mealy and easily crumbled. When four or five days old commence feeding curds, and give all the sour milk they will drink. Chop Onion tops and Lettuce, and give with the food until they commence picking the young and tender grass. Twice or three times a week give a little pepper in the food. Pour boiling water on the pepper, steep a few minutes, and then mix a few spoonfuls of this pepper tea in the food. Do not make too strong, too much pepper does more harm than good. When they are from a week to ten days old commence adding well-cooked corn meal to their daily food, increasing the quantity day by day until at five or six weeks they are able to take full rations of meal and boiled Potatoes. When six or eight weeks old you may feed cracked corn or Wheat screenings at night. From the time when you commence feeding the young Turkeys until after they are fully feathered and have thrown out the red on their heads, feed five or six times a day; then if insects be plenty they will thrive on two meals a day—cooked corn meal and Potatoes in the morning, and cracked corn or other grain at night. Sometimes grasshoppers are so numerous that Turkeys will thrive on a small ration of grain once a day, and some seasons I have turned my young Turkeys (after they were well feathered up) out without any breakfast, and they always came home at night with full crops; but I always threw them a few handfuls of grain to keep them in the habit of coming home to roost.

Keep your Turkeys growing from the start if you expect them to pay well when you send them to market. Do not imagine that you can half starve them until a few weeks before thanksgiving, and

then stuff them so that they will weigh as much as your neighbours' fowls that have been well fed from the shell.

This may sound like a great deal of work, and you may think that I am inclined to be "fussy" and particular about my Turkey feed. Well, I am particular about it, because I have learned that it will not do to feed young Turkeys anything and everything just as it happens. Feeding meal too soon, feeding uncooked meal, and feeding grain before they are able to digest it, will kill fully one-half of your brood. It is some work to prepare proper food for young Turkeys, but successful Turkey-raising pays so well that one can well afford to do a little extra work. After you get into the way of it you will find that the extra work does not amount to much after all.

Dampness is another cause of the great mortality among young Turkeys. Chills and cramps caused by tramping around in the wet grass puts an end to the lives of a goodly number of the infant Turks. You must keep your young Turkeys dry and comfortable during the first ten or twelve weeks of their lives—or until they are fully feathered and have thrown out the red on their heads. For a few days after they are hatched, whether you raise them with a hen mother or a Turkey mother, confine them to the coop and pen that I have described; then if all appear strong and well, open the pen and give the mother and her brood free range every pleasant day as soon as the sun has dried the dew off the grass. A hen mother will be very apt to bring her brood home at nightfall, but for the first few nights you will have to drive the Turkey mother home; else she will squat down wherever night happens to overtake her, and get up in the morning and drag her brood around through the wet grass long before you think of getting out of bed. After you have driven her home a few nights she will probably come without any urging, especially if you always give her a good meal after she gets into the pen.

Should a sudden shower come up while your young Turkeys are out foraging, turn out and drive them to their coops. If any get chilled and refuse to eat take them to the house, dry and warm them thoroughly, return to the mother, and give all a good feed with plenty of red pepper or ginger mixed in. After they have thrown out the red young Turkeys are hardy, and will stand almost anything.—FANNY FIELD (in *American Prairie Farmer*).

### TOY PIGEONS.

#### ORIENTAL TURBITS OR TURBITEENS.

SOME ten years ago the curiosity of Turbit fanciers was excited by rumours that there existed in the East Turbits of such deep and rich colours that the very best English birds and the soundest in colour would pale beside them. We must confess to having once been somewhat sceptical as to the marvellous superiority of these foreign strains. At last one or two gentlemen, who happened both to have business in the Levant and to be Pigeon fanciers in England, imported a number of these oriental birds. Their colours were indeed startling to our English eyes—deep red with a glow on it resembling burnished copper, intense black with a purple sheen, and yellow as sound as that of a Swallow, yet brighter. But their form and markings? Well, these were not at all what Turbit fanciers hoped for to improve their strains, and at once showed the breed to be practically another sub-variety, which soon were named Turbiteens.

Turbiteens are for the most part plain-headed; some have been imported with peaks, and these are more valuable to English fanciers, though we believe not more prized by their breeders, as having one more point in common with Turbits, and so affording more chance of good results from a cross. They are decidedly coarser than highly bred English Turbits, resembling in size the larger shell-crested Turbits imported from Germany. Their heads are rounder and more like English Owls; their eyes are frequently "broken"—i.e., of two colours curiously divided; their wings marked like Turbits, but their heads also (unfortunately for English fanciers) marked with a small coloured semicircle on the forehead and a large circle on each side of the face. They have feathered feet and hocks, and the latter are generally coloured. We have, too, seen them with coloured tails like some Turbits of old, now talked of but never seen. Their gait is proud, and their heads are generally thrown back. Their breasts are frilled, but we have never seen one with anything like a full double frill. The first importation came from Smyrna, and made, as might be expected, quite a sensation among English fanciers. As is the case with imported Owls, many of these Turbiteens were irregularly marked; but such as had the desired markings clearly defined and were good in head properties, especially if a good pair of them could be matched, commanded high prices. A beautiful pair of Blacks came into the possession of a renowned dealer and

exhibitor, and for a while seldom failed to score victories in the Variety class; but fashion is fickle in Pigeons as in other things, and we have seldom seen them of late in the prize list. After a time another importation followed, from Egypt as we were informed. By this time many Turbit fanciers were desirous of securing them in hopes of infusing their colour into their Turbit strains, for in addition to its brilliancy, report was rife that this colour did not fade, like that of the English Turbits, from exposure to sun and wet. High prices were asked for single birds. We succeeded in securing one, by no means a model bird as a Turbit, but on this account perhaps the more useful. He was a bright red, peak-crested, the only one of his colour we have ever seen with a peak, with little feather on his legs, and to a great extent devoid of the Turbit head markings. We mated him first with a famous Red hen, and subsequently with a Yellow. His produce, always Red, were in the first generation quite as much marked as himself, but mated again with a pure Turbit produced in the second generation birds almost equal to their grand-parent in colour, yet in many cases with no trace of the foreign marking. They have often stood in the prize list; and their colour, and that of others produced in like way by other fanciers is, we believe, far richer and sounder than anything that had before been seen in Turbits.

We must not, however, mislead young fanciers into thinking that all difficulty in the introduction of such alien blood is so soon overcome, or that we can retain all the desired points of each breed and discard the undesirable ones. In the third and fourth generation birds which have but one-eighth or one-sixteenth of Turbit blood often show as much marking as the original cock, and the curious eye of their quaint ancestor sometimes reappears. We have since had other Turbiteens, but the result of crossing them with Turbits has not by any means led to such satisfactory results; indeed, we have generally stamped out all trace of them and destroyed their produce. We remember one in particular, a black-shouldered cock with black tail, which we had much reason to think was picked up in Tangiers; he was small, and had a perfect head and peak, save that the latter was set too low, but all his produce were intensely coarse and lacked all his beauties.

We should add that the original Red bird once paired himself to a Black, and their produce were spangled almost like Satinets. Such has been our experience in Turbiteens—not a very extensive one indeed, but enough to show a young fancier that the experiment of crossing them with Turbits is very interesting, and that it is possible to improve greatly the latter breed by a series of judicious matches. Colour and hardihood we have certainly gained; in occasional foul feathers and wry peaks we have certainly lost. The chief interest of pedigree-breeding lies in selecting the few from the many. If all produce came perfect our pursuit would be almost at an end, and the necessity of rejecting many birds with faults of feather or form only leads us to prize more highly those at length obtained as the reward of patience, in which the chief beauties of two races are really brought together.—C.

## DOUBLE FLOWERS—A PROTEST.

**W**HENCE the love of flowers, which seems inherent more or less in every human breast? Well, we confess we have just propounded a question which we fear we cannot answer, and will not attempt to do so. It is a love which exists, however, which is a living power for good, and we sincerely pity the man who is incapable of being moved by the quiet unobtrusive beauty of flowers.

The beauty of flowers! How the simple expression transports one from the smoke-bound, brick or stone-pent town, and even the comfortable country home when the snows of winter mantle the earth, to the dewy dell in spring time when the Buttercups dot the emerald grass; the Wood Anemone waves its spotless flowers in response to the zephyrs of May; the Primroses and "Cowslips wan that hang the pensive head," peep out shamefacedly from among their cushions of clustering leaves; and "the wec, modest, crimson-tipped flower"—the Daisy—welcomes the returning summer. Such a picture floats before the writer's vision as he pens these lines. He can almost fancy he hears the exultant shouts of the school-boys and girls—some of them, alas! no more—as the Free Church school of Pitlessie is "skelt" at noon; and he can again recall the sight of the little bands that used to flock—still flock—to Priestfield "den" to gather abundant handfuls of Primroses mingled with other simple wild flowers.

It is said, and there is truth in the assertion, that it is the association of extraneous thoughts with the recurring annual bloom of "old-fashioned" flowers which cause many persons to cling so attachedly to them. While admitting that there is some truth in this, we imagine that it is the simple beauty, unsophisticated beauty, of the flowers themselves which yields the greater power. We admit at once that, while admiring all beautiful flowers, there are some to which we are fondly attached, and to none more so than simple Primroses. "Ah!" some reader may exclaim, "that proves the power of association of ideas." Not so fast, my friend. We have a strong affection for simple forms of Primroses, no matter whence they come, but that affection does not extend to all the tribe. For instance, our heart goes out in tenderness towards the Abyssinian one (*Primula verticillata*), while we love not, and scarcely even admire, the double forms of our own much-loved *Primula veris*. If association of ideas only rules, how comes it that the foreigner with its simplicity charms so much, and the companion of our childhood fails to do so when transformed—we very nearly wrote deformed, into a

wispy multiplicity of petals? Again, we grow as well as we can and we admire the fine "perfected" forms of the Chinese Primrose, but its gaudy beauty fails to awaken half the emotion which the little white *P. viscosa* (commonly called *P. nivalis*) does, and yet both are foreigners alike. The double Chinese or other Primroses we look upon as being very useful for bouquets or cut-flower work generally, or affording an appearance at a dull season; but as for their possessing beauty in its highest type, we emphatically deny it. The highest beauty consists of simplicity and elegance combined with delicacy of colour.

Double flowers in general possess neither simplicity nor elegance. They are mostly ungainly monstrosities; and as for delicacy of colouring, the single flowers nearly possess a monopoly of it. Why is the Primrose, the wild Daisy, or the Buttercup so much admired and cherished, and the Dandelion held in contempt? It surely cannot be that we were less familiar with Dandelions in youth than with Buttercups or Primroses. It cannot be that its peculiar shade of yellow is its condemnation. No, but it is gaudy, it is inelegant, it is a wisp of petals; hence it is a failure, a "hissing and a bye-word"—and—and a model for the florists! Double Daisies are more showy when planted in masses; but will anybody say they are more beautiful individually than the common one? Are the petals (florets) better formed, are they more snowy white, are they so beautifully tinted, are they as simply elegant as the single common ones of the fields and roadsides? Emphatically no. And are double Pelargoniums finer than single ones? Are they half so fine? When cut they stand better, and that is their only recommendation. We are unable to see very much beauty even in single Zonals; but as for the doubles, we would as soon think of getting enthusiastic over a bundle of red rags! They are showy, so is a red cart when newly painted. They are gay, so is a soldier's coat; but who dare call them beautiful?

And double Roses. Are they more beautiful than our wild ones? True, they are, many of them, bigger; but is our sense of the beautiful to be measured by inches? True, they have more petals; but is beauty become a matter of arithmetic? Is a flower with six petals more beautiful than one with five? Is not the flower with the five better every way if the extra petal destroys the beautiful symmetry, which is half the charm in single flowers? And have the florists not by their derangement of this symmetry—which is what has been done in ninety-nine cases out of every hundred where the addition of more petals to a perfectly formed flower has been the object—done a great deal to destroy beauty? I for one think the florists and others who strive to "improve" our flowers have all gone on the wrong track. It is time for them to learn that the mere enlargement of a flower from the size of a shilling to the size of a florin is not of itself improvement, nor yet is the multiplication of petals. Let us have elegance, by which I mean symmetry, purity and delicacy of colouring; but are greater diameters and increased numbers of petals elements of beauty?

Moreover, it is surely not a necessary qualification that flowers should be exactly round. A waggon wheel is surely a poor model for an improver to aim at, and yet something equivalent is kept in view. Flowers assume many shapes, and yet this very variety in form is one of the charms of plants and flowers. Yet with all the hubbub the florists make about

securing variety, they are doing their best to destroy it. Petals must be broadened, smoothed, narrowed, lengthened, shortened, till something as near the shape of a penny in the case of single flowers, or the half of a Turnip in the case of double flowers, is gained. We are treated to variety in colour, but as to form—the florists sigh because they have not yet been able to destroy it. And yet Nature is prodigal in her gifts even in this direction. The greatest charm of our wild flowers is their variety of form; the greatest want in improved flowers is the want of diversity of form. Among all the productions of the florist where are to be found the like of the Orchids? And yet these are, almost every one of them, wild flowers. Purity of colouring, delicacy of colouring, wealth of colouring, wealth of form—these characterise the Orchids. Why cannot our florists learn something from such as these? Even here, too, the florist has stepped in; and although the “improving” of form by means of raising seedlings is out of the question, he is attempting something by means of selection. The nearer the flowers of *Odontoglossum Alexandræ* approach the circular form the more value is attached to them. The nearer flowers approach to an artificial model and become thereby more artificial, the more beautiful they are considered! The sooner something better is substituted for this false taste the better. We have said false taste, but the fact is, it is bad taste, and we do not long for double Orchids.

To-day we stood by a tiny stream in a sequestered spot and gazed on clumps of Buttercups a yard across, perfectly covered with gleaming golden flowers. To-day we waded through a bed of Wood Anemones more than an acre in extent, and we sat by a mossy bank begemmed with modest Primroses, experiencing something like what the first dwellers in Eden may be supposed to have felt when ushered into existence, endowed with power to drink in all the glad joy prepared for them, not the least of which must have been a profusion of wild flowers. On the table before us a few of these Buttercups, Anemones, Daisies, and Primroses are side by side with fine-laced Polyanthus, garden Anemones, and garden Daisies, and we unhesitatingly say that the simple wild flowers are more lovely by far than even our favourite garden varieties. We would like to have them all, but we love the wild ones best.

Hard by the bed of Anemones referred to is another equally large of the wild Hyacinth, which will not be in bloom for some time yet; but when it does bloom the effect must be glorious. We have strips of plantations round the little place here where we serve, and we would fain carpet them with the sweet denizens of the wild woods, and shall be glad of any instructions whereby we may be enabled to succeed in establishing them. We think we shall have no difficulty in getting permission to dig up any number of Anemone roots and Hyacinth bulbs, and these we intend dibbling-in in clumps, say in October, in a shady plantation which has been kept free of grass by poultry hitherto, and will be now by the hoe. We intend to make trenches with bottoms puddled with clay—our soil is open below at the particular spot where we intend doing this—and filled with loam for growing clumps of Buttercups, the roots of which in their native spots are always bathed in water. Has anyone ever tried to cultivate these flowers, and if so will they please state by what means they succeeded?

I see that “WYLD SAVAGE” and others are taking up the matter. I think what they have said must have met responses in every breast where a love of wild flowers dwells. It is time, and more than time, that our native Flora received the attention it deserves. Let us all help on the good work.—SINGLE-HANDED.

“SWEET NANCY.”—Previous to the year 1844 there had been from “time immemorial” a kind of flower market associated with a swarm of humble florists and tiny nursery gardens in the Bethnal Green portion of the Cambridge Heath Road. “Sweet Nancy” was always there in the spring time, and her companions were Sweet William, Narcissus, Ragged Robin, and other gay sparks. Everybody knows Sweet Nan by other names, such as London Pride, *Saxifraga umbrosa*, &c., &c. There is a lot of it in the front gardens of smallish houses in the suburbs of Manchester, where I have heard it called Sweet Nancy, but with

different vowel sounds to those that were used in Bethnal Green.—SHIRLEY HIBBERD.

[*Saxifraga umbrosa*, or London Pride, is called None-so-Pretty, Pretty Nancy, and Sweet Nancy in different localities.—ED.]

#### SEASONABLE NOTES ON POTATOES.

POTATO cultivators throughout the country will now be watching their crops eagerly to try and form an idea of their prospects for 1881. I have never seen the Potatoes about here look better at this time of year than they are now; late varieties are growing strongly, and earlier kinds are very robust.

In many instances it is the common practice to plant the Potato crop and allow it to take its chance without any attention whatever until the tubers are ready for digging. Sometimes earthing-up is done early, other times late, and often not at all. The plants grow under all these conditions, but the improvement of the crop must be very uncertain. Potatoes are often unavoidably planted in heavy soil; this may be in good working condition at the time they are planted, but after much rain it becomes close and hard on the surface. Soil of the kind requires to be stirred frequently from the time the growths are seen above ground until the crop is well advanced. An ordinary Dutch hoe is little good. A steel fork should be used, or an implement the shape of a drag hoe, but with three or four prongs, is also useful for loosening stiff surfaces; it is worked in the same fashion as the drag hoe, and is excellent amongst Potatoes. I employ it amongst all ours as soon as we can see the plants and again before they are earthed up. Where the ground was not properly manured before the tubers were planted the deficiency should be made good before earthing up. A little potash will be found the best of all manures for Potatoes, failing this a mixture of salt and soot will do much good. I place a handful round each plant, covering a strip about 8 inches or 10 inches wide all round the plant; this is done just before earthing up, and the soil then covers the dressing. Potatoes treated in this way will always be very free from worms, and these are very troublesome and destructive in some soils.

The object of earthing up Potatoes is at all times to cover the surface tubers and prevent them becoming green. Some kinds form their roots deeper than others. Schoolmaster is one of the surface-rooting varieties, and kinds like this may sometimes require to be earthed up twice. When this is necessary the first earthing may be done when the stems are 8 or 10 inches high, and again before the soil between the rows is covered by the stems and leaves. In heavy soils this second earthing does much good, as Potatoes are just as much benefited by stirring the soil amongst them as other crops. At the present time our late Potatoes, now only a few inches high, are being subjected to surface cultivation, as the soil is being loosened between them; and in another ten days or so they will have their first earthing-up, and in another fortnight or so after that they will be finally earthed.

To secure large tubers some growers reduce all the stems from each set to two, but this very often reduces the number of the tubers too; and although too much top growth is an evil, I think four stems from each set give the best crop. But strong stems are not all that is wanted to produce a good crop: sometimes those with the greatest amount of top growth have the fewest tubers. Magnum Bonum is one of the kinds which makes enormous haulm; but I cannot understand the advantage of it, as the crop, although good and free from disease, is not heavier than that of others with a few short stems. Apart from heavy growth being no advantage it may even be injurious, as it is generally understood that the roots are not so fine when excluded from the air as those more exposed. I am thinking about restricting the top growth of some of our Potatoes this year by taking the points out of the stems when they have grown a reasonable height. I have done this before now in a small way with no deterioration of the crop, and I think it might be generally applied to some varieties. More air will be admitted to the soil, and the benefit will be great where the plan of planting winter greens between the Potatoes is carried out. I have heard cultivators say their Potato stems were taller than themselves, but this did not prove much; and probably if the growth had been restricted to 2 feet or so in a few rows they might have been astonished to find that these surpassed the giants in size, number, and quality of the tuber.

If Potatoes will bear restricting generally there would be great gain by it, as many kinds might be grown much closer than they are if the top growth had not to be taken into consideration. This would be an interesting experiment for many to try: Supposing a number of rows of each kind are growing together, stop the stems of one row when they are 12 inches high or so, and allow the others to grow in the old way. Judging from my expe-

rience the experimental row would not be the last on which the operation would be tried.—J. MUIR.

### THREE HANDSOME FLOWERING TREES.

ON visiting a friend's garden a few days since I greatly admired some flowering trees, which, it appears to me, are not sufficiently well known. Everyone that saw them in flower expressed the highest admiration of them. One was *Pyrus baccata*, with pure white flowers over an inch in diameter and deliciously perfumed. The tree was 18 feet high and probably as much through, covered with bloom. *P. spectabilis* is a good companion to the former; the flowers are rosy pink, and have a tendency to come semi-double. The third is the double-flowered Cherry, *Cerasus japonica flore-pleno*, pure white with flowers an inch across, very double, and reminding one of small Roses. If these three trees were planted judiciously in borders and shrubberies they would produce a very pleasing effect. Why they are not more extensively planted it is difficult to imagine. They grow quickly, and if only a limited space can be spared for them they can be readily kept in bounds by annual pruning, and lifting and replanting the trees occasionally.—W. K.

### OLD AND NEW PEACH TREE TRAINING.

I WOULD like to thank "SINGLE-HANDED" for his information concerning old authors who have advocated "extension" in Peach culture. I am pleased to note any evidence, new or old, in favour of a system that I believe in. Whatever may have been written on the subject, however, in times past, it seems manifest from much that is being written now that our knowledge of the system has been almost lost. We have but to turn to the revised edition of the "Gardeners' Assistant," published in 1878, and in which some additional illustrations on Peach training and pruning are introduced by its reviser, Mr. Moore, one of the Editors of the *Gardeners' Chronicle*, to see the kind of pruning and training advocated by such writers who, whatever their position and ability may be, certainly claim to stand in the forefront of modern horticulturists. The illustrations on Peach pruning in the new edition are the worst examples of mutilation it is possible to conceive. Fig. 280, page 453, represents a succession Peach shoot, which the pruner is shown must be cut clean off at the third bud from the base, leaving the shoot perhaps 3 inches at the most in length. Fig. 281 shows a branch with two succession shoots, in which the same method is more carefully delineated; and in the same page we are informed that Peach pruning "is reduced to three very simple rules:—1st, Shortening the intended bearing shoot at the winter pruning; 2nd, Training a succession shoot in summer; 3rd, The removal of the shoots that have borne fruit, except such of them as are leading shoots or branches." From what source the reviser of the "Gardeners' Assistant" got his examples is not stated, but in all my experience I never saw the like, nor never met anybody who did. There can be no mistake about the meaning of the author. The figures are not simple diagrams, but carefully executed illustrations of *bonâ-fide* Peach shoots, showing both fruit and leaf buds, and the lines for the cut by the knife at the winter pruning are drawn above the third bud from the base of the shoot in each case. Following these directions the pruner would cut about 9 inches from a well-ripened Peach shoot 12 inches long, and longer shoots in proportion; and this practice is advocated for general Peach culture on walls and trellises, but which fortunately no experienced men follow, though no doubt many beginners and readers of the "Assistant" have attempted to put in practice and failed, to their own and their employers' serious disadvantage. It seems to me to be time some one was lifting a voice against such mutilation of our fruit trees.

Whatever objections may be entertained to the system of training advocated by me, the following facts will, I daresay, not be unacceptable to those of your readers who are interested in fruit culture. One of the severest and most enlightened criticisms that have been passed upon my practice was that others might fail if I succeeded; but I hope I am not prohibited from telling what I have done, or that cultivators are deterred from following me if they choose to do so. From four young Peaches and Nectarines planted here in 1878, and hardly larger than maidens, I gathered in 1879 about eighteen dozen good fruit, as the trees bore from four to five dozen fruit each. In 1880 the same trees bore from nine to thirteen dozen, and at the present time they have each upon them from twelve to sixteen or seventeen dozen about the stoning period. I shall probably thin them down yet considerably; but if they do as well as they promise at present and have done before, I shall have gathered in less than four years from

the date of planting between ninety and a hundred dozen fruit or thereabouts, striking the average as near as possible, and speaking within bounds. Probably Mr. Pettigrew and others who have been so long ahead of me in the matter may have equalled or excelled this, and if they have I should be glad to be furnished with particulars. So far these trees are pushing strongly near the trunk, and I anticipate no difficulty in keeping the trees furnished with wood.

Kindly permit me also to correct an error fallen into by your reviewer in his allusion to the Peach tree at Wortley. The tree in question was planted in 1866, and was 15 feet across at the end of the third year. It was confined to this space till December, 1878, and since then it has more than doubled its diameter. The time taken is really five years and a little while longer to reach the top of the house. The tree is to be seen, and the evidences of its removal too, and what is stated can be proved. These statements will be found more than corroborated, and reference to page 500 of the "Gardener" for 1870, where the same trees are described at that time.—J. SIMPSON, *Wortley*.

[It will not be needful for our reviewer to reply to this communication, as Mr. Simpson's statements as to the size and character of the tree have not been questioned. The yield of the young trees alluded to is excellent.—ED.]

### ADONISES.

A SMALL group of plants, containing both annual and perennial kinds, with showy Anemone-like flowers. Two annual species are natives of England, a fact which too often leads to even a handsome plant being turned out of the garden. In the present case, however, they are really deserving a place in the shrubbery border. Some of the species are very nearly allied, and it is not necessary to grow all those described in the following notes where space is limited, yet they are well worth attention where they can be accommodated. The perennial kinds should be planted in situations where they may remain undisturbed for some years, for they do not like their roots broken. Any good garden soil suits these plants, but if it should be stiff and heavy they will not thrive freely, as they decidedly prefer a light, rich, and retentive compost. The species are all confined to Europe and Asia, and are perfectly hardy.

*A. æstivalis*.—An annual species, and a weed in common parlance, but in the month of May travellers crossing Salisbury Plain often see it in fine condition. It forms a much-branched compact plant, attaining a height of about 2 feet. The leaves are very finely divided and deep green. Flowers bright scarlet and very showy. It blooms during May and June. Seeds should be sown in the borders in September. Britain.

*A. autumnalis*.—This is also an annual plant, which, as its name implies, flowers at a different time of year. It grows about 1 foot high, and is distinguished from the preceding by the length of its sepals, which do not exceed the calyx, whilst in the spring-flowering plant they are much longer; the colour rich crimson, approaching to black towards the base. It blooms in July, August, and September, and is sometimes known by the name of "Red Morocco." Britain.

*A. pyrenaica*.—A perennial plant which has been neglected—like all its relatives, indeed—but this has been cast aside on the plea of its being only a taller-growing *A. vernalis*. It may be described briefly as a gigantic form of that plant; but it must be borne in mind that the flowers also are larger, whilst, instead of being solitary, they are produced three to five on each stem. The leaves are much divided into narrow deep green segments; they appear larger than its near ally through having long footstalks, whilst the bright golden yellow Poppy-like flowers are often 4 inches across. It attains a height of about 18 inches, and flowers in July. Pyrenees.

*A. vernalis*.—This plant certainly is one of our very finest spring flowers, but can only be seen in perfection where the soil is congenial and it has been allowed to stand undisturbed for some years. Then, indeed, it presents a picture which would defy an artist to render. The leaves are sessile, much divided into narrow, linear, deep green segments. Flowers terminal, solitary, about 2 to 3 inches in diameter, Poppy-like, and rich bright yellow. It attains a height of about 10 to 15 inches, seldom, however, exceeding a foot. If the season is genial it commences flowering in the month of March. Mountainous parts of Europe.—H.

GRUBS ON ROSES.—"Look after the grubs," says "D., Deal," on page 372; "now is the time to make the onslaught." I always mind what the parson says; so I have spent the evening while

light served in looking over the Rose bushes in my little garden, pouncing upon wriggling caterpillars, squashing fat brown grubs in the leaves, and digging out others from the stem. I did not number the slain and will not send you fancy figures, but I killed a host. I thought I was acquainted with all the enemies of the Rose, but an unknown stranger has made his appearance in my garden. White spots appear on the leaves, the leaf being eaten away on the under side and only the upper cuticle left. On turning up the leaf a small grub a quarter of an inch long appears holding on by its head, its body encased in a brown envelope projecting from the leaf at right angles. Can any of your readers tell me the name of the "little beggar?"—EDWARD LESTER.

### BROCCOLI ON FIRM GROUND.

SOME twelve months ago there appeared in this Journal an excellent article from the pen of Mr. Wright, about planting Broccoli on hard ground. This I had never practised nor seen carried out in previous years, and I was therefore anxious to give what I thought a good system a fair trial, not merely for the sake of testing the advice there given, but for the purpose of growing the plants more solid and hardy, so as to reduce the death rate amongst my plants if possible, as it was enormous during the winter of 1879 and 1880. The system referred to appeared to me to be the most likely by which that end could be achieved, and the result proved very satisfactory. Two portions of ground were selected that had the previous year being occupied with late Peas and Beans, and the ground in consequence was firm. A moderate dressing of manure was applied and just forked in below the surface, so as to allow of small drills being drawn about 3 inches deep for the young plants when ready (a system I generally carry out in planting the Brassicas). The seed was sown in an open position about the middle of April, and the seedlings produced grew slowly, but sturdily. Cattell's Eclipse and Leamington were the two kinds selected, and when between 2 and 3 inches high they were finally planted upon the firm ground in rows 2 feet 6 inches apart, and the same distance from plant to plant. At first growth was slow, but when well established they soon covered the space allotted them. In autumn the stems were thick and hard, and the plants dwarf and sturdy; all were lifted, and their heads laid to the north on the same portion of ground. Of the former eight out of every ten passed the winter safely, while about half the latter were left alive; both are now producing fine heads. Late Qucen, recommended by some as the hardiest of all Broccoli, died with me treated in every respect the same as the preceding varieties. Those grown upon deeply dug rich soil, including the above, Carters' Champion, and Harrison's Late White, all succumbed to the effects of the severe weather; the thermometer registering on one occasion as low a temperature as zero.—WM. BARDNEY.

### ROYAL HORTICULTURAL SOCIETY.

OWING to the report of the Scientific Committee and the Rev. G. Henslow's lecture not reaching us sufficiently early last week, we were compelled to defer their publication until the present issue.

**SCIENTIFIC COMMITTEE.**—*Sarracenia*.—Mr. Smith made some additional remarks on the petals of this plant, having come to the conclusion that they rose when in a saturated atmosphere, in consequence of a strong light being thrown upon them. He exhibited a drawing to show how the uplifting of the petals would facilitate the ingress and egress of insects.

**The Influence of the Electric Light on Plants.**—Mr. Buchanan exhibited Wheat plants sown on December 17th in the open air and subjected to the electric light. They came up slowly and were covered with snow. Several plants perished, but the remainder have grown very rapidly during the last five weeks. They were vigorous and green. They were about 15 feet from the light, which shone upon them every and all night. He also exhibited a Melon planted on November 6th. The light, however, was at too great a distance; hence the plant grew very weakly. When, however, the light was subsequently brought nearer in January last it made rapid progress. The question was raised as to the flavour, but Mr. Buchanan observed that no opportunity as yet had occurred of making comparative experiments with those grown in sunlight. A vote of thanks was given unanimously to Mr. Buchanan for his interesting observations.

**Elisena.**—Col. Clarke exhibited a hybrid between *E. longipetala* and *Ismene callisthena*, and which appeared to be identical with *I. deflexa*. The uppermost stamens were sharply bent down and across the tube of the perianth, as in *Ismene*, but the lower were declinate, as in *Elisena*. He also exhibited *Tulipa undulatifolia* and others, as well as *Cyrtanthus McOwani*.

**Abies Nordmanniana.**—Boughs cut by the frost were exhibited by Dr. Masters. It appears that they had perished through the thaw rather than the frost, for they had been bowed down by snow which melted, and were then subjected to a hot sun. The violence of the

contrast in temperatures caused their death. Col. Clarke observed that Silver Firs and Norway Spruces had lost their leaders during the late winter, while Mr. Wilson remarked that *Cupressus Lawsoniana* had also been killed.

**Thorns.**—Dr. Masters recorded a remarkable instance of a Hawthorn around which a wire had been fixed to support a Rose tree. The wire had completely cut through the tree in ten years, but the wound had healed up, so that the tree had been quite uninjured. He also mentioned the case of a Hawthorn whose stem had been split for about a yard in length, the whole of the length had spontaneously reunited.

Mr. E. Davies forwarded examples of Primroses with virescent corollas from Swansea; Pansy with blue posterior petals. Mr. Noble exhibited a seedling with remarkable petals, apparently indicating a new departure in the distribution of colour. It was an accidental seedling.

Mr. Buchanan mentioned the case of a Crab tree caught within the fork of a Beech and completely embedded in it. The effect appeared to be that the Crab tree blossomed much earlier than others in the neighbourhood.

Mr. Henslow exhibited Daffodils in which the membranous spathe had dehiscent in a circumscissile manner, entirely cutting off the upper part. He also showed "Jack in the Green" Primroses from a plant found wild in Ireland. He exhibited some Willow catkins forwarded by Mr. Marshall of Ely, who had observed that those from monandrous Willows always flowered from the apex downwards, whereas catkins from the triandrous Willows flowered from the base upwards.

**LECTURE.**—The Rev. G. Henslow took the tribe "Pomeæ" of the Rose family (Rosaceæ) as the subject of his remarks, as Mr. Barron exhibited several branches of Apple trees illustrating considerable varieties of form, size, colour, &c., in their blossoms. He described the flower of the Apple, and pointed out the affinities with the Plum, Blackberry, Strawberry, and Rose, as well as the differences, especially in the characters of their fruits respectively, which separated them. He dwelt upon the so-called "calyx-tube," or rather "receptacular-tube," and showed how it was characteristic of the whole family under modified forms, constituting the thin tube of the Cherry, the flat dish-like process in the Blackberry and Strawberry, the haw of the Rose, and the fleshy part of the fruit of the Apple, Pear, &c.

As the season of the year has arrived when frosts prove most disastrous to fruit trees, the lecturer proceeded to make some remarks upon it. He first observed the importance of understanding the external conditions which were favourable or otherwise to the acquisition of hardiness by plants. One of the most important facts is, that in low-lying situations (if away from any large body of water, which might act as a radiator of heat and so moderate the temperature in its neighbourhood) frost almost invariably proved more destructive to vegetation than on higher and more exposed situations. That such was the case had long been observed. Mr. Henslow ventured to offer the following explanation:—In the first place valleys accumulate heat, and being naturally moist vegetation is earlier, more stimulated, and later in drawing its period of activity to a close; hence there would be a less capability of ripening wood and hardening the constitution in autumn. It is then in a condition likely to suffer. On the other hand, when frosts occur the atmosphere is clear and comparatively free from moisture, so that radiation can proceed rapidly and without interruption. Now, since moisture is slow to acquire heat and equally slow in parting with it, from this fact alone one would be inclined to infer that the temperature of valleys ought to be slower in reaching the freezing point than that of higher ground. But evaporation from a moist surface would take place, especially under just those atmospheric conditions which favour frost; and it is this (the lecturer suggested) which was probably the cause of the increased lowering of temperature, since to evaporate water a considerable amount of heat is required, as may readily be recognised by wetting the finger and allowing it to dry by evaporation.

The chief cause, however, of valleys being colder than the higher situations at night was probably that, although radiation takes place from both, yet in consequence of the air on higher ground being more agitated than that in the valleys, no portion of it rests long enough in one place to become much colder than the general mass of the atmosphere of the same height. Moreover, the chilled air on the hills being heavier, slides down into the valley, making room for the arrival of a fresh supply of warmer air. With regard to spring frosts, what usually caused them to be so disastrous was a previous condition of wet, as so often occurs in April. When vegetation is started the tissues are loaded with moving sap; then if a frost comes, and a bright hot day follows, the sudden transitions of temperature prove disastrous. If the frozen trees be syringed early in the morning with cold water, so as to raise their temperature slightly above the freezing point, the intense heat of a May sun may be powerless to injure the tree.

The presence of a surface of water near fruit trees has been suggested as a preventive of frost, just as pails of water are sometimes placed in storerooms, which are said to protect Apples, Potatoes, &c., from being frostbitten, while the water in the pail itself is frozen. If it be correct, the interpretation would seem to be that in order for water to freeze it must part with a relatively large amount of heat; this is distributed to the atmosphere about it, and its temperature will be obviously raised. The lecturer suggested that fruit-growers should experiment on this point by placing pails or troughs

at the foot of the walls whereon Peaches, &c., grew, leaving certain other trees in the same situation without the water, so as to test the truth of the assertion.

Besides adopting any methods which may keep the air above freezing point, protection against radiation is especially to be considered. It is astonishing what a very slight protection will sometimes suffice. Various fruit trees in which the petals were more incurved than others will thereby protect the pistil from injury; while Cherries, in which the withered calyx-tube was observed still suspended on the summit of the ovary before falling off, were thereby protected, while others from which it had fallen were cut on the same occasion.

Such were some of Nature's hints as to what was requisite to protect the blossoms from the injury of frost.

#### ABOUT PEACH TREES.

THERE are certain questions about which there is hardly room for discussion. It may, I think, be taken for granted that during all times the grower with few trees and much space would extend the branches. But about pruning and cropping, do gardeners practise what they preach? I have seldom seen them do so, but frequently have seen them with crops which evidenced that they considered their prestige depended thereon, and others with bearing wood tied in as though they contemplated during the winter months turning basket makers! Let me impress upon young gardeners the adoption of the following plan: Say a young tree with six branches is at hand. Give the bottom pair just a gentle rise and divide the rest equally, with the exception of giving to the top pair two spaces. When disbudding remove all the back shoots and all the bottom shoots, and remove those in the front with the exception of a few, which pinch short to form fruit spurs. With a sunless season the fruit buds of these latter, requiring less ripening, may save a crop, and they clothe the tree. On the top of the branches leave shoots for bearing about 18 inches apart. Thus you will have a fan-shaped tree formed of "wings," and you will never be troubled whilst laying in your wood with one lateral running into the other; so you will have a tree that will please the eye and secure fruit with ordinary attention. Of course I do not offer this as any new plan, but I do offer it as a plan that deserves attention, and yet a plan that is very far from being practised generally by professional gardeners.—JOSEPH WITHERSPOON.

#### RHODODENDRON CAUCASICUM PICTUM.

ON the 6th of April we lifted a large plant of the above from the open border and placed it in the plant stove for cutting. On the 13th, exactly a week after the operation, sixteen fine heads of open flowers were cut from the plant, and the evening of that day the specimen was a mass of beautiful pink flowers. On the 14th 136 open trusses were cut, leaving about sixty remaining, counting buds as well. This is a first-rate forcing variety. We have grown it for many years, having it in flower frequently about the beginning of the year for conservatory work, when it lasts a long time in flower. I do not think its use for forcing is as well known as it deserves to be. It is freely used in this locality (Cheshire) under the name here given, and also there is a fine white variety which we have not grown. A plant of a red kind was lifted here before the 6th of April and put in the early vinery, and it is not yet (May 7th) fully in flower. But most people who force plants know the great difference of Rhododendrons in this respect. *R. c. pictum* is now just coming into flower in the borders, and is very pretty; only for this work it is risky to grow it too largely, as it is sometimes completely cut down by late frosts when it is in full flower.—R. MACKELLAR.

#### CARPET BEDDING.

AFTER all that has been written against this mode of garden decoration it has yet probably more admirers than any other, judging by the thousands who enjoy it in the London parks, and the long pilgrimages that are made to them for securing the latest patterns. The system is also largely practised on the lawns and terraces of private gardens, as we know by the inquiries we receive on the subject. The present being the time for arranging the beds, we submit the first of a few examples designed by Mr. Graham of Hampton Court, which are quite different from any he has hitherto produced. The arrangement for a whole ground-work of the attractive dark green hardy plant, *Herniaria glabra*, will considerably reduce the expense of planting such a bed. The margin, No. 11, had better be raised about 5 inches above the grass, slightly bevelled, and planted with *Echeveria*, *Sedum glaucum*, or both together, to keep up the soil and improve the appearance of the bed. This design can be planted in many different ways

to suit the taste or variety of plants at command, and with certain modifications that will suggest themselves the character of the design may be adapted to beds different in form to the one repre-

Fig. 86.

sented. The following is a mode of planting suitable for the design submitted:—

1. *Echeveria metallica*, or any other suitable specimen plant.
2. *Alternanthera amoena*.
3. " *paronychioides major*.
4. *Pachyphytum bracteosum* or *Kleinia repens*.
5. *Alternanthera paronychioides*.
6. *Sempervivum montanum*.
7. *Mesembryanthemum cordifolium variegatum*.
8. *Herniaria glabra*.
9. *Sempervivum tabulaforme*, or plant of a similar character.
10. *Alternanthera* of any kind.
11. *Echeveria secunda glauca* interspersed with *Sedum glaucum*.

JOTTINGS FROM THE WEST.—I was very much pleased to see "VERNA" alluding to our plants of the hedgerows, copses, &c. I am particularly partial to our British "weeds," as gardeners too frequently call them. No matter how severe our winters, they are always succeeded by charming spring flowers, such as *Petasites fragrans*, three species of *Potentilla*, one or two varieties of *Viola*, three species of *Ranunculi*, the Daisy, Primrose, wild Hyacinth, the Hawthorn and Blackthorn, and a great many

more. Our crops of early Potatoes are promising. Those at Scilly are quite three weeks behind their usual time this year, owing to the severe frosts in early spring. An excellent sample was produced out of doors at Galval, which were dug about three weeks ago—remarkably early. Hyacinths and Tulips have been finer this year than for many previous seasons, owing, I presume, partly to the excellent bulbs imported last year.—W. ROBERTS, *Penzance*.

THE Royal Horticultural and Agricultural Society of Antwerp announce that on the occasion of the fiftieth anniversary of the Independence of Belgium an INTERNATIONAL EXHIBITION will be held in Antwerp on the 14th, 15th, and 16th of August of the present year. The schedule enumerates 142 classes in eight divisions devoted to the following exhibits:—First, new plants, ten classes; second, flowering plants, sixty classes; third, fine-foilage plants, forty classes; fourth, specimen plants, fourteen classes; fifth, bouquets, &c., five classes; sixth, fruits and vegetables, nine classes; seventh, pictures of plants, fruits, or flowers; and eighth, garden instruments. The most important prizes are the following:—The King's large gold medal offered for a group of plants; the Queen's large gold medal for the best collection of Orchids; a gold medal, value 500 francs, offered by Le Fédération des Sociétés d'Horticulture de Belgique for a group of ornamental plants and specimens; with gold medals of honour, value each 200 francs, offered by M. le Baron de Caters, President of the Society, by M. Le Baron Osy de Wycken, Vice-President of the Society, and by the members of the Council. Many other gold medals of similar value are also offered in various classes, and judging by the provision made a highly satisfactory exhibition should be the result. M. Charles Van der Linden is the Secretary of the Society.

— It is announced that the INTERNATIONAL POTATO EXHIBITION for the present year will be held on September the 20th and 21st. The schedule enumerates nineteen classes, in the majority of which the prizes have been considerably increased in value, and many additional prizes are offered. For instance, in eight classes four prizes are now offered in which there were only three last year. Class C, for twelve dishes, is especially devoted to English Potatoes; Class D, for nine dishes, being reserved for American varieties, and several other alterations are notable. Four classes are devoted to new Potatoes, accompanied with the following stipulation, that "as the granting of certificates will be conditional upon the approval by the Judges of the seedlings when cooked, a dish of not less than six additional tubers of the same variety must be provided for the purpose."

— THE extensive collection of CYCADS AT KEW is now in admirable condition, and we have never seen the plants growing so vigorously as they are at the present time. The majority of the specimens are arranged to form a large group at the south end of the Palm house, and the numerous crowns of light green leaves now arising contrast strikingly with the older darker leaves. In some instances over thirty leaves are being produced from one crown. Several handsome specimens of *Encephalartos Frederici Gulielmi* are particularly noteworthy, and *Dion edule* with many others are similarly vigorous. Admirers of this class of plants would do well to visit the Kew collection during the present month.

— A CORRESPONDENT, "RUS," desires to recommend SWEET OIL AS AN INSECTICIDE, as he finds "it kills both bug and scale,

and does not injure the young shoots of plants." We advise that it be applied with caution, as we apprehend its frequent use would be injurious to vegetation.

— THERE is now a beautiful display of ORCHIDS AT WIMBLEDON HOUSE, and the collection has been formed and the plants grown in a remarkably short space of time. Particularly noteworthy are some excellent forms of *Odontoglossum Alexandrae* and *O. Roezlii*, also several *Dendrobiums*, including *D. Devonianum*, *D. tortile*, with some fine examples of *D. primulinum* on the eve of expansion. The growths made in small pots and saucers are wonderful, and they show beyond doubt that Orchids may easily be, as they often are, overpotted. In the same small pots *Pleiones* are growing luxuriantly, as also are *Odontoglossum vexillarium* and *Phalaenopsids*. *Aerides Fieldingi* is producing fine spikes; indeed the entire collection is in most excellent order. Pitcher-plants, too, are making great progress, and many valuable specimens are established. The Vines, about fifty years old, in the same garden have never looked so well as at present, and they show what can be effected by a judicious system of renovation. The Peach trees and crops grown in the manner described by Mr. Pettigrew on page 327 are remarkably fine, and could not be surpassed in appearance nor excelled in productiveness by trees grown on the extension form pure and simple.

— IN the outside department of the same establishment the UNPRUNED PEAR TREES are such as would gladden the eyes of Mr. Simpson. For some years the pruning of the trees has been limited to the thinning-out of superfluous branches, no shortening having been done; indeed several trees have not been touched with the knife since they were quite young. Many of the Pears are now about 15 feet high and half as much in diameter at the base, and are handsome well-formed pyramids. The Apples of bush form are such as it would be difficult to find fault with, as they are of agreeable form and laden with blossom. They have borne good crops during the last few years, and this year a full yield is expected. In passing through the gardens so well stocked, and the pleasure grounds so diversified and beautiful, the visitor cannot suppress a feeling of regret that this picturesque estate is not long expected to remain in its present form. It will, however, afford scope for the erection of many attractive if smaller houses after the proprietor, Sir Henry Peek, Bart., has removed to his new mansion and estate in Devonshire.

— WE are sorry to learn that the frost on Thursday morning last destroyed a great portion of the blossom on the Apples at Chiswick, the smaller trees most severely; even the unexpanded flowers were nipped, and Pears were slightly injured.

— WE understand that a STRAWBERRY FETE is proposed to be held in the Royal Horticultural Society's Gardens at Chiswick this year, and that a circular is being sent to the Fellows of the Society on this subject.

— IN one of the houses at the Royal Botanic Society's Gardens, Regent's Park, a plant of the peculiar *ARISTOLOCHIA GOLDIEANA*, which was figured in this Journal, vol. xxxviii, page 456, is now bearing several flower buds; so there is a possibility that lovers of the curious forms of vegetation may shortly have an opportunity of seeing the extraordinary flowers of Goldie's Birthwort.

— WRITING from the West of England a correspondent states, "The bloom on all kinds of FRUIT TREES has been unusually abundant this season. Unfortunately on the night of the 10th the temperature fell to 25°. This severe frost has much injured the Apple blossom both expanded and in a bud state, and has also affected the crops of Gooseberries, Red and Black Currants. The majority of the Pears, Plums, and Cherries had set good crops, and are apparently uninjured. All the early Straw-

berry bloom have now been twice injured, and the Potatoes are cut to the ground."

— LAST week, observes a daily contemporary, the King and Queen of Belgium gave a GARDEN PARTY AT THE PALACE OF LAEKEN, BRUSSELS, the first ever given in Belgium. The newly constructed winter garden was opened on the occasion. There are magnificent conservatories for Palms, Azaleas, and exotics of every kind, and connected with the apartments of the Palace by an underground gallery adorned with plants. The diplomatic body and the *élite* of Brussels society were present. The *fête* was splendid and favoured by the weather.

— WE have pleasure in publishing the following letter in reference to the GARDENERS' ROYAL BENEVOLENT INSTITUTION—

"I have had numerous inquiries as to the way in which the simultaneous collection on the 30th July is to be carried out. Will you kindly inform your numerous readers that a collecting card will be sent on or about the 22nd July to every gardener whose address I can find? but as there must be many whose names and addresses are not in the horticultural directories, I shall be greatly obliged to any gardener whose name is not in those works, but who at the same time is willing to assist the cause, if he will write to me, and I will see he has a card sent him.—EDWD. R. CUTLER, *Secretary, 14, Tavistock Row, Covent Garden, London, W.C.*"

— ON Friday and Saturday next a FLORAL EXHIBITION will be held at the Alexandra Palace, when liberal prizes will be offered for table decorations, bouquets, and Roses in pots. In the class for nine Roses in pots, size not stipulated, the first prize is £18, the second £9, and the third £4; while for ten Roses in 10-inch pots the prizes are £6, £3, and £1 respectively.

— A CORRESPONDENT, "VITEX," informs us, "That there is at the present time in flower in The Gardens, Elmfield, Ullet Road, Liverpool, the residence of Thomas Holden, Esq., a plant of the best variety of IMANTOPHYLLUM MINIATUM bearing twenty heads of bloom, with from twenty to twenty-four flowers on each. It has been very much admired by all who have seen it, and is a noble plant." Our correspondent desires information relative to the best plant hitherto flowered in this country, and a reference to a plant grown at Sheffield. We are unable to indicate the "best plant in the country," but the Sheffield plant is described on page 275, April 8th, 1880.

— THE EXCELSIOR LAWN MOWER of Messrs. Chadborn and Coldwell is an American form of this useful implement, and possesses many points which exhibit American ingenuity in mechanical matters. The great feature of this lawn-mower is the complete protection of the wheels and mechanism from injury and from clogging with grass clippings and earth, which is too much the case in some patterns we have seen. We have used the Excelsior and found it perform its work perfectly. It is so easily propelled that a lady might work it, and the grass can be distributed on the lawn or collected in the box as is deemed the most desirable.

— REFRESHING SHOWERS have fallen in the neighbourhood of London during the past few days, and have been of great benefit, especially to newly-planted shrubs and flowers. We learn that in the sandy districts of West Surrey both garden and farm crops have suffered much from the prolonged drought, and that Potatoes have been killed to the ground by the sharp frosts of last week.

— "L." WRITES:—"Some time since I noticed in the garden at Yardley Wood Vicarage, near Birmingham, a very simple but tasteful ARRANGEMENT OF BULBS. Clumps of the large-flowered Snowdrop, *Galanthus nivalis* McIlvillei, were planted at intervals, and were alone extremely beautiful, but their appearance was still further enhanced by each clump being encircled with plants of the brilliant blue *Scilla siberica*. The effect of this contrast was most charming, and considerably more attractive than the lines of Hyacinths a short distance away, though these were fine

and comprised some excellent varieties. The Rev. J. A. Williams is so well known as an ardent amateur rosarian, that the only regret I felt on my visit was that it had not been delayed until the rosy month of June, when I should have the pleasure of seeing his pets in their best condition."

— WHEN in such fine condition as it may now be seen at Regent's Park, TULIP COMTE DE MIRABEAU can scarcely be equalled for massing in beds; even the old and useful White Pottbakker is almost outrivalled. In a bed there among many others of more or less beauty this variety is especially notable for the pure white, medium-sized, well-formed flowers, and their great regularity of height. In striking contrast with this are fine beds of Yellow Prince, Cottage Maid, Cramoisie Superbe, Keyzers Kroon, and Joost Van Vondel, well arranged and planted.

— A CORRESPONDENT observes:—"One of the most attractive and ORIGINAL BOUQUETS that I have seen for some time I recently noticed in the grand row of Covent Garden Market. It was composed of Maréchal Niel Rose buds and half-expanded blooms, the yellow Marguerite (*Chrysanthemum Etoile d'Or*), and a large rich purple self Pansy. These were arranged informally with fronds of *Adiantum cuneatum* and *A. gracillimum*. The simplicity and freedom of the design and the contrast of the colours rendered the bouquet by far the most beautiful, to my mind, of all in the market."

— WE have repeatedly referred in praiseworthy terms to LETTS'S POPULAR ATLAS as it was issued in monthly parts, but as we have now before us the first complete volume of the series it deserves a few words of commendation as a whole. It contains thirty-six maps delineating all the most important countries and districts of the world, indicating with surprising clearness and fidelity the most minute details, and comprising much statistical and general geographical information of considerable value. A very complete index of 23,000 names is an additional recommendation to the cheapest and most satisfactory atlas we have seen.

— WE have received a copy of a small work by Mr. D. T. Fish, published at the Bazaar office, and entitled "THE CHERRY AND MEDLAR." It gives outlines of the history of both fruits, with particulars of propagation, planting, pruning, training, and general culture, and appears to be fairly accurate and reliable. The fourth part of the same author's treatise on "Bulbs and Bulb Culture" has also been received, which comprises cultural details relating to *Ixias*, *Sparaxis*, *Irises*, and other similar plants, accompanied by several highly unsatisfactory woodcuts.

— MR. PETER HENDERSON contributes the following upon MOSS-MULCHING to the "American Gardener's Monthly."—"We have now practiced moss-mulching most extensively for over a year, and in no single instance have we seen any fungus on the roots of the plants that could be ascribed to moss-mulching. It is true that a few days after the mulching of moss and bone is put on, probably for a week, a mould or fungus appears on the surface of the "mulch," but this is in no way injurious. We find that its use promiscuously on plants is only safe from, say, March to October. We use it even in midwinter on gross-feeding plants such as Callas, Dracenas, Palms, and plants of that character. But we found that plants that were in a partially dormant state and are grown at a low temperature, such as Azaleas and Camellias, are better without it. I think in the summer months, on Azaleas particularly, is most beneficial and marked. At the date we write (April 4) nearly every plant in our establishment, as soon as it is established in anything over a 3-inch pot, is submitted to the moss-mulching process, which we will continue throughout the entire season.

— WE are requested to remind our readers that an ASPARAGUS COMPETITION will be held in the horticultural department of the Bath and West of England Society's Show at Tunbridge Wells, commencing on Monday, June 6th. Notice from those desiring to compete should be given to the Secretary of the horticultural department, the Hon. and Rev. J. T. Boscawen, Show Yard, Tunbridge Wells. All exhibits should be staged on the morning of Monday, not later than twelve o'clock. The following prizes are offered for the first year's Exhibition, and are (except the last two for market growers in Kent), open to growers in any part of the United Kingdom. *Prizes for Gardeners in Private Places.*—For the best bundle of Asparagus grown by the exhibitor—first prize, £4; second, £2 10s.; third, £1 10s.; fourth, £1. The bundle of Asparagus is to consist of sixty heads. The prizes will be given to the largest Asparagus, provided it be in all other respects unobjectionable. Prizes will not be given where in the opinion of the Judge there is no merit. The Asparagus must be free of earth, and the bundles will be opened by the Judges in all cases where they think it well to do so. No imperfect or "double" heads will count. *Prizes for Amateurs not Employing any Regular Gardener.*—For the best fifty heads—£2 10s.; second prize, £1 10s.; third prize, 15s. Grown by the exhibitor. *Prizes for Cottagers.*—For the best twenty-five heads grown by the exhibitor—£1 10s.; second, £1; third, 10s.; fourth, 5s. *Prizes for Market Growers.*—For the market grower who shall exhibit the best three bundles, each containing one hundred heads—£5 5s. This prize is offered by the Bath and West of England Society. For the market grower in the county of Kent who shall exhibit the two best bundles of Asparagus, each containing one hundred heads—first prize, £3 3s.; second, £2 2s.

#### FRUIT-GROWING IN KENT.

WE sometimes find large books with little in them besides words, but occasionally a small work crowded with instructive, suggestive, and interesting matter comes before us. Such an one is a small manual of thirty-two pages by Mr. Charles Whitehead, F.L.S., Barming House, Maidstone, which originally appeared as an essay in the Journal of the Royal Agricultural Society, and from which we take the following extract:—

An improvement has taken place in the management of fruit land in Kent during the past twenty-five years; and at the same time greater facilities of transit and a steadily increasing demand have led growers to add largely to their plantations. This is proved by the Agricultural Returns, which show an increase of 1031 acres in 1880 over the return of 1879; the acreage of arable or grass lands used for fruit in Kent being 14,645 acres in 1880, as against 12,032 acres in 1875.

Foreign competition has assumed enormous proportions, and is becoming more formidable each year. The imports of raw fruit in 1875 from the chief importing countries were:—Belgium, 703,777 bushels; France, 581,170; Holland, 199,860; Spain, 199,650; the United States, 164,160; Germany, 146,493. In 1879 the imports of raw fruit from these countries were:—Belgium, 962,983 bushels; France, 477,473; Holland, 598,952; Spain, 429,116; the United States, 734,904; Germany, 418,778, showing an enormous aggregate increase. This has stimulated Kentish producers to pay greater attention to the cultivation and management of fruit land as well as to the selection of better and more attractive sorts.

Though a certain amount of improvement has taken place in the methods of fruit-culture, there is still much to be done as regards selection of sorts, the methods of planting, the actual cultivation, and the pruning of the trees. The delicate and important operation of pruning, which makes all the difference between high and low production, is, it must be confessed, but imperfectly understood by many Kentish fruit-growers and their tree-cutters or pruners. Instead of the careful selection of the wood most likely to bear fruit—in place of a *raison d'être* applied to every stroke of the knife—the typical tree-cutter hacks and slashes away ruthlessly, aiming principally at obtaining a symmetrical cup-shaped form rather than at retaining the wood most likely to bear fruit. He is paid by the tree, and cannot afford pauses for reflection as to individual shoots or buds, like the careful interested pruners in France and Belgium, or like some of the best English gardeners.

It was formerly the prevalent notion, still holding to some extent, that fruit trees require but little manure. Apple and Cherry orchard lands were mown or fed off with lean sheep year after year, with the result that the trees only bore a crop once in two years, and the fruit

grew small by degrees and beautifully less. The owners of the celebrated Cherry orchards in East Kent have found out the folly of starving the trees. For the last few years they have manured the land liberally with manure brought from the London stables and cow-sheds, which has largely increased the quantity and improved the quality of the fruit. Sheep fed with corn and cake feed off the grass, and it is now quite the exception to mow orchard land.

It might be supposed that Kentish fruit-growers, only forty miles distant from London, would not be affected in any great degree by the competition of foreigners in the matter of soft fruit—i.e., fruit of a perishable nature, as Gooseberries, Raspberries, Currants, and Strawberries; yet, as a fact, the cost of carriage of a ton of fruit from France to the London Docks is no more than from Maidstone to the London markets. Rents and labour are cheaper in France and Belgium, while the climate of the former country is far more suited for the production of fine well-flavoured fruits than our own. 962,983 bushels of raw fruit were sent to England in 1879 from Belgium, the value of which was £268,914. France sent 477,473 bushels, whose value was £264,908, showing that the quality of French fruit is far superior.

Fruiterers and salesmen say that the foreign fruit has much improved in flavour and size, and is steadily improving, while the imports are increasing year by year, as may be seen by the returns of the Board of Trade, which show that the total amount of "raw" fruit imported into England in 1879 had reached the enormous amount of 4,219,951 bushels, as against 1,128,568 bushels in 1871. France sends Strawberries, Cherries, Red Currants, Gages, Plums, Pears, and Apples; and sent to this country 477,473 bushels of "raw" fruit in 1879, against 354,606 bushels in 1871. Plums and Currants arrive from Belgium and Holland. Apples and Pears are imported from Spain. Immense quantities of Apples come from America, of fine quality and flavour, almost equal to Ribston or Cox's Pippins in good seasons. A large Covent Garden fruit merchant wrote on the 18th of December, ult.: "This day alone there are 16,394 barrels and 109 cases of Apples from America, to be sold by auction." In October last no less than 167,400 barrels of Apples were landed at Liverpool from America, equal to 502,000 bushels.

Two principal systems or methods of planting fruit prevail in Kent. One, according to which it is intended that the land under the standard trees shall be eventually laid down with grass; the other, where the land will always be cultivated and kept constantly filled with fruit trees and bushes under the standards or half-standards.

East Kent growers for the most part adopt the former method, because it is not good for Cherry trees that their roots should be disturbed after a certain time. The standard trees are planted first on well-prepared arable land, with Hops or fruit bushes, which give a return until the standards come in. When these have arrived at a good size the Hops and bushes are taken away and grass seeds are sown. Apple orchards are occasionally formed in this way; but Apples are generally grown on the other system—in permanent plantations set out and planted with Plums, Damsons, Gooseberries and Currants (and Filberts in some parts of the Mid Kent district), which are renewed from time to time as occasion requires. In an orchard which is eventually to be laid down with grass, the standard trees, if Cherry trees, are set from 33 feet to 24 feet apart each way, giving forty to eighty trees to the acre. If Apples are planted they are set about the same distance apart. Plums or Damsons are very often put between Apples or Cherries, and are taken out when they get in the way. In a plantation that is to be permanently cultivated the Apple trees are set about 30 feet apart. Plums or Damsons would be set in between each Apple tree, and Gooseberries and Currants between the rows, 6½ feet apart, so that there would be 44 Apple trees, 44 Plum or Damson trees, and 1031 bushels on each acre. Where Filberts are grown under Apples they are usually planted about 13 feet apart, which would give about 257 trees to the acre, and Plums or Damsons are not generally planted in this case. The cost of preparing the land and of planting it as a mixed plantation with all incidental expenses, varies from £16 to £20 per acre, according to the sorts and number of trees planted. Apple trees cost 1s. 6d. each on an average. Plums and Damsons 1s. each. Filbert and Cob trees 4d. each. Gooseberry and Currant bushes from 10s. to 14s. per 100. The annual average cost of cultivation, including rent, interest on outlay, tithes ordinary and extraordinary, rates, maintenance, and other expenses, exclusive of all charges connected with picking and selling the crop, which would, of course, depend upon its amount, ranges from £13 to £16 per acre.

In the Weald of Kent Apples are principally grown on grass land, the fruit grown in this way being of a somewhat better colour and quality than that which has been produced on cultivated land; and practical men hold that, independently of this, all Apples grown on the Weald clay and Hastings sand are superior in colour and size and make better cider than the fruit grown in other parts of Kent, though there is not much difference as regards quantity. It is certain that Apples grown on grass are not so liable to specks and blemishes. In the formation of an Apple orchard intended for grass, it is found in practice to be best to plant the trees on well trenched land, and to lay it down after a few years, when the trees are well established. I have planted Apple trees of the excellent variety known as "Lord Suffield" on grass land and on cultivated land at the same time, both being manured in the same way; those on the cultivated land grew away from those on grass in a remarkable degree, and bore fruit

the second year, while the others did not bear for three or four years.

Not nearly enough attention is paid to pruning the trees after they have become fair-sized. Now and then a raid is made upon those that are most bushy, which are hacked and cut about unmercifully, and it is not strange that Apple trees of the best sorts, invariably the most delicate, decay prematurely. Very few growers prune their Apple trees scientifically, or manage them thoroughly in other respects. Here and there a plantation may be found where the trees have received systematic and proper treatment from the date of planting, where good fruit is produced in abundance; and it is asserted confidently that the land in Kent really suitable for Apple-growing may be made to yield fruit not much inferior in quality to the traditional Nonpareils, Scarlet Nonpareils, Golden, and Ribston Pippins, and other sorts whose sweet memories linger yet in the recollection of Apple-loving octogenarians.

The chief sorts of Apples grown in Kent are, commencing with dessert Apples, the Ribston Pippin—*facile princeps* among Apples—now unfortunately a somewhat shy bearer. The King Pippin is much grown in Mid Kent and the Weald; this is a handsome Apple when well grown, but it is inclined to be specky on the ragstone, though doing better on the Weald clay. Joannettings and Summer Pippins, early Apples, are also grown and bring good prices. Red Quarrendens, Farleigh Pippins, Pearmaines, Nonpareils, Golden Knobs, which ordinarily keep well until Apples come round again, bringing high prices, are found in most Kentish plantations and orchards. The Court of Wick is also grown. The Margil, whose flavour is nearly equal to that of the Ribston, is too shy a bearer, and is not therefore extensively grown. The Blenheim Orange, a large handsome Apple, is much grown near Maidstone and in the Weald. Cox's Orange Pippin has been planted extensively of late. This is a high-class Apple for dessert from November to January, supposed to have been raised from a pip of a Ribston Pippin. The Sturmer Pippin is a most valuable late Apple.

The principal cooking Apples grown in Kent are Keswick Codlins, Gooseberry Pippins, Hawthorndens, Warner's Kings, Northern Greenings, Wellingtons, Winter Queenings—all valuable sorts; the Golden Noble, Lord Suffield, a very fine-flavoured early-bearing sort, the Tower of Glamis, the Manx Codlin, and the Stone Apple, or Lodington Seedling.

As many as 500 bushels per acre have been grown in plantations where the trees were in their prime. Taking an average of seven years of the average Apple-growing land in the county, the crop per acre per annum would be about 130 bushels. The average price per bushel for Apples home to the grower, for the last ten years, has been about 2s. 2½d.; the expenses of picking, packing, carriage, commission, and return of sieves, amounting to about 1s. 4d. per bushel, having been deducted. For the preceding ten years the average price, clear of all these expenses, was about 1s. 10d. per bushel. The annual yield per acre of the orchards under grass must be regarded as being 20 per cent. larger than that of the plantations in respect of Apples; but the average annual yield of both taken together amounts to about the quantity of bushels stated above. The fruit-growers in Kent do not appear to have tried growing upon a large scale Apples and Pears on low bush-trees obtained by working upon the Paradise stocks, whose influence tends to dwarf the habit of growth and to produce fruit abundantly. These bushes can be easily pruned, and root-pruned if thought desirable. There are several plantations of these near London, one notably at Chiswick, belonging to Mr. Dancer, who grows quantities of the finest fruit upon this system, which is thought might be adopted successfully by the large fruit-growers in Kent.

There is much more similarly interesting in the able essay from which we have cited. It is published by Effingham Wilson, Royal Exchange, London.

#### TRITONIA HYALINA.

TRITONIAS are well known and valued in many gardens, such species as *T. aurea* and *T. crocata* with their numerous varieties proving useful additions to our conservatory or greenhouse plants; but the one represented in fig. 87 is, when in good condition, unquestionably the finest of all, and at the present season it can be scarcely rivalled in the brilliancy of its orange-coloured flowers by any other plant grown in cool structures. The plant from which the specimen sent was taken was grown in the greenhouse at Orsett Hall, Romford, the residence of Captain Wingfield Baker, and the effect produced by several small examples arranged on the side stages as a margin to the larger plants was very bright and pleasing. Two or three bulbs are grown in a 60-size pot, ordinary light sandy soil being employed with good drainage, and very little difficulty appears to be experienced in inducing the plants to flower freely. But perhaps Mr. R. Castle, the gardener, may give our readers a few notes on the treatment he finds successful for such plants.

The plant was received there under the name of *Tritonia aurea*, but it differs considerably from the finest varieties of that species; and on a specimen being submitted to Mr. J. G. Baker of Kew, who

is a very high authority on the nomenclature of Iridaceous plants, he at once determined it to be *T. hyalina*, so named by himself in his elaborate description of the order, and considered to be synonymous with *T. fenestrata*. Its most marked character is the peculiar transparency of the lower half of the petals exactly resembling thin glass, and to that circumstance it owes the specific name *hyalina*. The upper portion of the petals is rounded and of a bright orange hue, five or six flowers being borne on a scape 8 or 9 inches high sufficiently to raise them above the tapering leaves. *T. fenestrata*, which is said to be synonymous with *T. hyalina*, was figured in the "Botanical Magazine" in 1803; t. 704, but appears to differ slightly from the one represented here, as the petals are somewhat widely separated, though the peculiar transparency is similar in both. Those who desire a brilliantly

Fig. 87.—*Tritonia hyalina*.

coloured bulbous plant for greenhouse and conservatory decoration at this period of the year cannot err by growing this fine *Tritonia*; the flowers also last well when cut and the stem placed in water, hence are valuable for furnishing vases and using in bouquets.

**AURICULA CLASSIFICATION—MEALD CENTRES.**—In the very interesting lecture, which you were good enough to find space for, delivered by the Rev. Mr. Horner at South Kensington, there was much to interest, and some points that, with his usual courtesy, that gentleman I am sure will not object to still further add to, especially for the information of amateurs like myself having only a few years' experience in Auricula culture. Mr. Horner says, speaking generally, "Auriculas are divided into two grand classes, with mealed and unmealed centres—the former the Auricula Royal of the florist, and the latter Alpines, having the essential qualities of unmealed centres and heavily shaded petals." Now I should like some information on what may be called a

sub-section of the 'former, that for want of a better designation I would like to call mealed Alpines, but that from the above classification the term is inadmissible—a paradox! I have some few seedlings with fine bright yellow eyes, mealed centres, and in most cases with the ground colour brown shaded to purple next the paste and becoming lighter towards the edge. Were such plants destitute of meal they would be shaded Alpines, like many others I have already; and were there no shading, but a heavy dull crimson or claret varying to a bright black with mealed centre, like others I grow outdoors, they would be termed, I presume, "selfs." I send a few pips of the mealed blooms already referred to, which are  $1\frac{1}{4}$  inch in diameter and very showy, though only grown in pots  $2\frac{1}{2}$  inches in diameter and seedlings of last year.—W. J. M., *Clonmel*.

[The flowers did not arrive in good condition.—ED.]

#### REVIEWS OF BOOKS.

*The Ladies' Mulum in Parro Flower Garden.* By SAMUEL WOOD. London: Crosby Lockwood & Co.

IN a recent notice of a much-esteemed church dignitary it was stated as a point in his favour, and as a mark of honour, that "he was not everlastingly writing books." No such honour as this can be conferred on Mr. Samuel Wood, nor can we congratulate the publishers on the books they are distributing from his pen on gardening subjects. Such essays as are conveyed in outwardly attractive volumes with catching titles would not be admitted in the columns of the gardening press. Mr. Wood may be a good gardener, but is certainly not a competent writer. We have in milder terms intimated this before, but as his publishers continue issuing works that are the reverse of creditable additions to garden literature it is necessary to speak more plainly. Referring to red spider "running about as if to save a house on fire," and describing thrips as "not larger than a fly's eye," and the common Tansy "as one of the most splendid carpet bedding plants we possess," can only provoke a smile, and incite wonder that such writings are printed; and yet the author has the assurance in his preface to the calendar to remark that "as a rule calendars are as common as weeds, and frequently not much better," &c. We will not refer further to this book except to remark, that although it contains some practical information, it is a pity Messrs. Crosby Lockwood & Co. did not submit the MS. to a competent horticultural editor for revision; then there would not have been sufficient of it left to form the book.

*Epitome of Gardening.* By THOMAS MOORE, F.L.S., F.R.H.S. Edinburgh: Adam & Charles Black.

A GLANCE at this book suffices to show that only a small portion of it has been written by Mr. Moore from his own knowledge and his own practice. Part I is an introductory chapter on the principles of horticulture by Dr. Masters, and is the most satisfactory portion of the book, worthy of being published separately in a cheap form. We are not able to indicate the writers of the remaining portion. The articles appear to have been compiled from various sources, some of which are acknowledged, but not all. For instance, our attention has been drawn to page 153, where the matter undoubtedly is substantially and in some striking instances literally the same as that on pages 15 and 16 in Mr. Simpson's book on training fruit trees that we recently reviewed, and there is reason to suppose that Mr. Moore has been indebted to the paper in which Mr. Simpson's articles appeared before being issued in book form for the instructions he has given on the page quoted; yet there is no intimation whatever that he is indebted to anybody. We have not searched for other examples of bookmaking in the volume, but it is quite apparent that nurserymen's catalogues and trade mediums have contributed to a considerable extent in furnishing the pages. We can scarcely conceive that a book of this kind is required by gardeners and horticulturists generally, dealing as it does in a necessarily brief and fragmentary manner with the rudiments of horticulture; but possibly, as is stated in the preface, there may be some others to whom such a manual may be acceptable. There are not, we are constrained to say, many good judges of books on horticulture who will consider that this volume will add to the literary reputation of the author and compiler; and it is a poor performance to have appeared in such a work as the "Encyclopædia Britannica," from which it has been reprinted.

*Horticultural Buildings.* By F. A. FAWKES. London: B. T. Basford, 52, High Holborn, and at this Office.

THIS is a rather elaborate volume treating on the construction, heating, and arrangement of horticultural buildings, with re-

marks on some of the principles involved in their construction. The author, as a member of the firm of Messrs. T. H. P. Dennis and Co. of Chelmsford, has had great experience in the work in question, and, as stated in the preface, he has "honestly endeavoured to treat the subject from an independent disinterested standpoint;" and, as is further stated, the work has been prepared because "up to the present date no book has existed from which a gentleman could obtain, in a complete concise form, unbiassed reliable information to assist him in deciding what garden structures would best suit his requirements; in which an architect could see just those constructional and mechanical points which should be decided by the horticulturist, and in which a gardener could find details beyond his province, but with which he should certainly be acquainted." Beyond question there is much in this volume that gardeners and all interested in the erection of horticultural buildings should be acquainted with, and it will prove a useful work of reference. The text is elucidated by numerous illustrations.

#### PORTRAITS OF NEW AND NOTABLE PLANTS.

*ROSA MICROPHYLLA.* (*Bot. Mag.*, t. 6548.)—The single or typical form of this old Rose is very well depicted in this plate, with representations of the distinct fruit which is said not to have been figured before. "All we know of its early history is that it was introduced from Canton into the Calcutta Botanic Gardens by Dr. D. Roxburgh, from whence it has been diffused into Indian gardens generally. . . . In its double form *Rosa microphylla* is commonly cultivated throughout China and Japan, and even in Upper Burma, Dr. Anderson having found it in Momgen. The fruit, which is as large as a Crab Apple, is eaten by the Japanese."

*ASTER GYMNOCEPHALUS.* (*Ibid.*, t. 6549.)—A pretty species of Aster from Mexico, with neatly formed bright rosy purple heads of flowers. The upper leaves are small, about an inch long, and have a deeply toothed or bristly margin; the lower leaves are 6 inches or more in length, with a distantly toothed margin. Professor Asa Gray states, in his description of the plant, that "This appears to be a common species throughout the northern and central parts of Mexico, and it occurs in almost all collections made in that region. It is here for the first time brought into cultivation from seeds collected in 1878 by Drs. Parry and Palmer in the vicinity of San Luis Potosi. It is a fine acquisition to the gardens, and its rosy purple rays distinguish it from all its near relatives." The plant is comparatively dwarf, as it only attains a height of 1 to 2 feet, and well deserves a place in a collection of hardy plants.

*IMPATIENS AMPHORATA.* (*Ibid.*, t. 6550.)—An annual Himalayan Balsam, attaining the height of 3 to 6 feet, and described as one of the handsomest species of that section. "It was introduced into Kew by seed from Kashmir, and flowers annually abundantly in the months of August and September. It was in cultivation forty years ago in the Horticultural Gardens, having been sent from the gardens of Saharunpore in North-west India, when these were under the superintendence of Dr. Royle."

*CLADRASTIS AMURENSIS.* (*Ibid.*, t. 6551.)—An East Asian representative of the American *Cladrastis virginica* (*Virgilia lutea*). It is a tree reaching the height of 40 feet, bearing pinnate leaves and long dense racemes of whitish flowers. Being quite hardy it is a decidedly useful addition to the shrubbery, and at Kew it produces its flowers freely in August. The specimens in that garden were contributed by M. Van Volxem of Brussels.

*AQUILEGIA FORMOSA.* (*Ibid.*, t. 6552.)—A very beautiful species of Columbine, nearly related to *Aquilegia canadensis*, with red and yellow flowers. The sepals have a bright yellow central band and bright red margins, the petals being yellow at the upper portion, and having very dark rich red spurs. Flowers of a yellow *Aquilegia* are also shown in the plate; the *A. flavescens* of the Rocky Mountains considered by Sir Joseph Hooker to be merely a variety of *A. formosa*.

**LIBERIAN COFFEE.**—Mr. Morris, the Director of Public Gardens and Plantations in Jamaica, has recently issued a pamphlet entitled "Notes on Liberian Coffee, its History and Cultivation." In this pamphlet Mr. Morris has brought together a great deal of valuable matter connected with this remarkable species of *Coffea*, which will prove not only interesting to those who wish to see the resources of our colonies developed, but particularly to those about to embark in the cultivation of Coffee as an article of commerce. The pamphlet commences with some historical remarks on the species, and then touches on its introduction into Jamaica, followed by a consideration of the plant as found in Liberia, in the West and East Indies, of its propagation and the establishing of plantations with regard to climate, soil, and various other details; some interesting notes follow on the yield of Liberian Coffee trees, and of the commercial value of the coffee itself. In view of this pamphlet being of considerable use to persons abroad who may be about to embark in the

cultivation of this particular species, we may say that it is issued from the Government Printing Establishment at Jamaica, and that its price is sixpence.—(*Nature.*)

#### DOUBLE-BLOSSOMED CHERRIES.

ORCHIDS and rare exotic plants generally are eminently worthy of the attention that they from time to time receive, but we must not overlook the merits of less rare occupants of our gardens that

contribute to their beauty during the spring months—namely, flowering trees and shrubs. Rare and costly exotics can only be grown by a comparatively small number of those who enjoy flowers, but hardy plants and trees can be grown by many and admired by all.

One of the most beautiful of all trees for the adornment of parks and pleasure grounds during the spring is the double-blossomed Cherry represented in the annexed engraving. Large specimens laden with thousands of large flowers are strikingly beautiful,

Fig. 88.—DOUBLE-FLOWERED CHERRY.

and it is somewhat surprising that a tree so conspicuously attractive is not more freely planted. There are several forms of double Cherries, but this is the most imposing of them all. The variety known as Waterer's is attractive by its rose-tinted flowers; the double form of the Morello, *Cerasus vulgaris*, arrests attention by its rosette-like blooms, as also does the Japanese species, *Cerasus japonica flore-pleno*; but for stately spreading beauty the variety figured from a spray brought from Chiswick is not surpassed.

The tree is known botanically as *Cerasus sylvestris flore-pleno*,

the specific name being that adopted by Ray and Bauhin, and is synonymous with Mönch's *Cerasus avium*, under which name the tree is generally known, and Linnæus's *Prunus avium*. It is named by the French, *Mérisier à fleurs doubles*, or *Merisier Renonculier*, and is sometimes seen in England under the name of the Double French White Cherry.

MR. WOODHEAD'S AURICULAS.—Enclosed I send you one of Mr. Woodhead's pips of Auriculas; it is a white edge, the best

I ever saw. In speaking of Auriculas it is an old but trite saying that "nothing will beat the old sorts;" but there is no mistake about the superiority of the flower enclosed. I will send you notes on the Auriculas in question shortly.—GEO. RUDD.

[The flower is undoubtedly of great merit, the white being firm and pure both in the paste and edge, the eye rich, and the body colour black; the flower is flat, smooth, and perfectly round, and the colours defined with great precision.—ED.]

#### RENDERING PEACH TREES FRUITFUL.

To produce Peaches in unheated glass structures may not appear a hard task to some, but under the following circumstances it proved to me a very great difficulty for years. The trees were in excellent health as to wood and leaves, always summer-pruned, and apparently well ripened. The flowers seemed to set well, but almost all the fruits dropped off as they commenced swelling. After many trials of the old soil of the border, which I found to be spongy, cut a trench round the trees 4 feet in diameter, or 2 feet from the stem, and filled up with old pasture soil and one-third lime rubbish. The following season the trees bore a fair crop, and have greatly improved, so that this year I have fine crops of healthy fruits, of which I enclose some specimens for your inspection. When the trees are in flower in spring I close the house early in the afternoon, and in autumn I close it every evening. I do not adopt any other mode of fertilising the flowers than by knocking the branches with my hand.—B. G. COMBER, *Co. Down*.

[The branch sent was an excellent example of fertility. Every blossom appeared to have set, and a great number of fruits will have to be removed from the trees.—ED.]

#### ODDS AND ENDS.

*Omphalodes verna*.—The large, bright, rich blue Forget-me-not-like flowers of this plant have been freely produced through April, and have a charming appearance in bouquets. It thrives in light well-drained soil where it is afforded slight shade in summer. On knolls of rockwork it succeeds admirably, having a partiality for stones of a sandy porous character; but it must have shade from hot summer sun, and as much light as possible in winter and spring. On slopes of light soil by woodland walks it is very pretty, the moderate shade afforded by deciduous trees suiting it perfectly. Propagation is readily effected by runners, which it produces freely in early summer. In order to have it in flower at an early season rooted runners or offsets should be planted in May in light soil on a north border 1 foot distance apart. The plants should be lifted in autumn, and planted in frames or pits with a south aspect in a sheltered position; the soil, which should be light and rich, not being more than a foot from the glass. Plants may be potted in autumn and transferred at intervals from early December to February to a house with a temperature of not over 50°.

*Myosotis dissitiflora*.—Beautiful as this is now (May) out of doors, being much later than usual, it is valuable in pots at the dull season. Plants should be potted in autumn, placed in a cold frame, and then arranged in a greenhouse or conservatory. Seeds may be sown now in pots or pans in gentle heat, and when the young plants appear remove them to a cold frame, and if planted out 9 inches apart in an open situation they will be suitable for lifting in autumn. The slips or cuttings should be inserted on a shady border.

*Helleborus colchicus*.—This, as frequently seen in gardens, and as I have had it hitherto, is confounded with *H. olympicus*, but it is very distinct. It flowered at the close of April outdoors. The flower stem and ternate leaves which accompany the flowers are a deep brownish purple; the flowers deep purple or plum with a coppery tinge. Height 12 inches. It is as hardy as any of the others, doing well in loamy soil somewhat moist.

*Calla (Richardia) aethiopica*.—Whether on the plant for decorative purposes or for cutting, the spathes of this are always appreciated. Plants that have flowered may be divided, planted out when frosts are gone in an open situation, sheltered if possible from wind, and be liberally supplied with liquid manure through the summer. At the end of September lift and pot the plants, giving a temperature of 45° to 50°. Care should be taken to harden them well off before planting out; and if they have been in houses in the shade of Vines the foliage must be inured to light, or the foliage will be scorched if the plants are brought from a warm shaded house suddenly. There is another method and much older. The plants are kept in the pots constantly, and often in the same pots for years without anything beyond rectify-

ing the drainage and top-dressing with old cow dung. Some plants may be in 12 to 15-inch pots, which form fine specimens for conservatories. After flowering and as soon as safe in spring they are stood on ashes in the full-sun. It is usually not advisable to place them outside before the middle of May, or better not till June, keeping them well supplied with water. The plants rest for a time and then grow strongly, which is the time to rectify the drainage, top-dress with cow dung, and supply liquid manure. By October some progress will have been made, and the plants must be housed: they should have a light position and a temperature of about 45°. It is important that the plants be marked. Those that have been started first may be marked 1, and so on in order. Where there is a number of vineries and Peach houses started at intervals from November or December onwards there will be no difficulty in keeping a succession of plants in flower from an early to a late period. Plants in an ordinary greenhouse will flower in April and May, and in a cool one but safe from frost somewhat later. Earlier spathes may be had by starting a batch of plants in October, or if necessary in September. Each strong crown will give two spathes, and in some instances three.

*Violets*.—These have been very fine. All outside have been killed except Queen, Victoria Regina, and the old Single White, and those were much injured. In frames and pits Victoria Regina was far ahead of all others in autumn, but inferior to Prince Consort in spring. Princess of Prussia is not nearly so hardy as those mentioned, and succeeded very indifferently. *Devoniensis* is fine in spring, but is no use for autumn and winter. Russian, Russian Superb, rubra simplex, obliqua striata, suavis (different from the Russian, as I have it) have been good. White Czar is the purest white of all Violets and very desirable, highly fragrant. The old White (*albiflora*) was fine in April. *Viola odorata* and var. alba, or the common wild single blue and white sweet-scented Violets, are very interesting, and much finer under cultivation than in a wild state. Among the doubles New York was more floriferous than De Parme, but is not nearly so hardy; similar remarks applying to Marie Louise as to New York in point of hardiness, and Neapolitan is more tender than any other of the type. Belle de Chatenay, though double and a better white than Queen, has not done half so well. King and Double Russian are very similar, the former being larger and not so freely increased. *Parmensis plena* is nearly white, tinged or striped rose, and very double. Blandyana, though not always to be depended on for its stripes, is a fine Violet; and Double Red (*rubra plena*) is a pale red colour. Arborea and A. alba plena are interesting, but must be kept in a greenhouse in winter to do well. *Argenteaflora* is very floriferous, not flowering in winter, but it flowered in March in frames, outdoors in April, and will continue through the summer if the runners are not removed.—G. ABBEY.

#### IXIAS AND SPARAXIS OUT OF DOORS.

HAVE any of your readers succeeded in growing these bulbs in the open garden? For four years I have endeavoured to do so, but without much success. I planted small bulbs as soon as I could obtain them in autumn or early winter; they soon started and they were protected, one season with leaf soil, another with cinders, and each time with a handlight. The second season I had a moderate display of flowers from some of the bulbs. I tried again, but the severe winter of 1879-80 cut them down again. However, in the autumn of 1880 I found not only had some of the bulbs survived but had produced several small ones. Last autumn I procured *Ixias*, *Sparaxis*, and *Babianas*, and planted them on the 30th of August, and on the approach of frost covered them with ashes and a handlight. They all grew vigorously and appeared most promising in February and March, but the last frost in April cut them all down to the ground; and I feel that it is hopeless to expect any bloom from them this year, but I see that some of the old bulbs which were left in the ground from previous years are growing. My experiments have not been successful, and still I think these beautiful flowers may be grown in our gardens as freely as the *Gladiolus*.

Have any of your readers tried planting the *Ixias* and *Sparaxis* in the open borders in spring, and in what months? and if so how have they preserved the bulbs through the winter months? Perhaps someone can tell me what is the natural habitat of these bulbs, and what kind of soil they require.—G. O. S.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 22. NEW SERIES.

THE larger beetles in the division of the *Phytophaga* are, as a group, harmless compared with the smaller and prolific species,

several of which we noticed in our last article. Bulky and rotund is the familiar sluggish insect that is popularly called the "Bloody-nose Beetle" (*Timarcha lœvigata*), because it readily ejects from the mouth a drop of red fluid when it is touched. Being partial to the hedgerows this insect occasionally appears on those which surround some garden plots, especially if they have been allowed to fall into a neglected condition. From a hedge the beetles are wafted perhaps by the breeze, and descend upon some plant where a gardener discovers them, and has his suspicions aroused. The unlucky *Timarcha* is generally doomed to destruction, though it is not one of those beetles that does any appreciable amount of mischief. Indeed the matured insect—which is of deep purple, almost black hue, dotted with tiny punctures which seem to give it a velvety gloss—does not eat much. Probably the larva has a good appetite, but its preference is for the low-growing plants in mixed hedgerows, where it hides judiciously, since the soft fat body might offer a temptation to hungry birds; though it is said (by those, I presume who have made experiment) that the juices secreted by both the larva and beetle are so bitter as to prevent the birds from meddling with them.

In the genus *Chrysomela* are reckoned nearly twenty British species, most of them of moderate size, globular in form, and brightly coloured, golden tints predominating, hence the name. Some of the species are injurious to trees, upon which, during seasons favourable to their increase, both larvæ and beetles are found in swarms. Like the preceding they have usually the power of emitting a dark (often strong-smelling) fluid either from the mouth or from the joints of the legs, that is apparently designed to keep off enemies. One curious circumstance connected with the history of several *Chrysomelæ* is, that the liquid they secrete has long had the repute of acting as a specific for pains in the teeth and jaws. A finger had to be well moistened with this and gently rubbed upon the part affected. If the cure is not to be ascribed to fancy there must be something of a sedative

Fig. 89.—Larva of *Chrysomela populi*.

nature in the fluid, which is possible; for the belief has certainly prevailed many years, and over a large area; one species indeed has been named *C. odontogicus*, but it has no claim to power more than its relatives possess (fig. 89). *C. populi* resorts to the Poplar and Sallow, a pretty insect, bronzed and red, capable of flying briskly if so inclined, but generally noticeable by day in the act of crawling upon the twigs. The larvæ are greyish, short-legged, and stout, abroad at times in sufficient numbers to strip whole branches of their leaves, but they do not affect the tree's life. Upon the Alder is found the blue beetle, and the green tubercled larva of *C. Alni*, while the Aspen is greatly infested by *C. tremulæ*, black and chestnut, with a preference for the soft portions of the leaf, all the fibres being cautiously avoided.

The Tortoise beetles are singularly formed; *Cassida viridis* is one of the commonest of these, occurring plentifully amongst Thistles. In gardens it has been taken upon the Artichoke. When these beetles are not in motion they draw the head and limbs completely under the thorax and wing-cases, which in colour nearly resemble the herbage, and thus escape capture unless the seeker is well acquainted with their habit. The larva of this species is flat, covered with spines, and it bears upon the tail a forked apparatus, which is characteristic of a *Cassida*. Few of the genus are taken in gardens, however, except as stragglers.

We have now reached the last section of the Coleoptera, the least of all the sections, and which from the three-jointed tarsus or shank is designated that of the Trimeræ. In this there are various small species, some of which are scarcely observed even by entomologists. The only important group to us is that which contains the ladybirds of popular phrase. These beetles are deserving of all the encouragement we can give them in our gardens and houses, as the persistent foes of aphides. Mr. Staveley and others have referred to them as if they were the principal destroyers of this blight; but useful though they are, we cannot allow them quite as much honour, the number of aphis-eaters being considerable and fluctuating with the season. No doubt in the autumn of most years the ladybirds and their larvæ appear conspicuously amongst the flocks of aphides; but during the spring, as I have already pointed out in this Journal, just at the time when the aphides are increasing rapidly and preparing for their May migration, the beetles in question are often to be seen in a somewhat inactive condition. Our cold spring has a depressing effect generally upon the *Coccinellæ*, but unless it is very moist the aphides are unaffected by it. The beetles hibernate, moreover,

and when in April they come forth to deposit eggs they have not quite recovered from their long sleep. As soon as the new brood of larvæ is hatched they begin to feed voraciously upon the aphides and considerably reduce their numbers.

The commoner species of the genus *Coccinella* are known to everybody. The body is flat below and rounded above, wing-cases rather soft, and antennæ short. One of their peculiarities is a tendency to vary in colour and markings, and in some species the forms and shades are so numerous that they present a puzzle to naturalists. For example, in the familiar seven-spotted species (*C. septempunctata*) not only do the spots vary in size, but one or more will be absent, and specimens are now and then taken that are without spots altogether. These, like some species of one family previously mentioned, have a propensity to discharge a fluid from the joints of the legs, which has not an agreeable odour. Ladybirds, or Ladycows our ancestors called these insects, under the belief that they were under the special protection of the Virgin, though this was before the value of the beetles and their larvæ as aphis-killers had been recognised. The name Ladycow may be presumed to bear reference to the fluid secreted by the species of *Coccinella*.

The larvæ of this species are of similar appearance, though differing from each other in size, being blackish or brown and freckled, with small heads, thickening towards the tail, by which they secure themselves to a leaf or twig while they feed (fig. 90). They also change to pupæ on the plants where they have fed, and these pupæ are sometimes destroyed on the supposition that they contain the germ of an injurious insect. *C. bipunctata*, the Two-spotted Ladybird, is of great service to the Hop-growers, but the species is so widely distributed that we find it everywhere upon plants infested with aphides. There are many varieties of this species, and a dozen or more species of about the same size which occur here and there.

Fig. 90.—Larva of a Ladybird (*Coccinella*).

One of these has a large number of spots (*C. 22-punctata*). Another species that is well known is *C. septempunctata*, exceeding the former in size, though still a small insect: this also appears in all our gardens, yet not in the abundance that is so notable with the two-spotted species. In average years there is one brood of each species, the beetles emerging towards the close of summer. The migrations of *Coccinellæ* have been often remarked upon in our periodicals: these are chiefly noticeable during August, and in *C. bipunctata* and *septempunctata*. Newspaper accounts, with their usual vagueness, have described the swarms of ladybirds as being "miles in extent;" and the appearance of hosts upon the coasts of Kent and Sussex, as in 1869, has led to the plausible supposition that they can cross the Channel in a favourable wind. To these journeys they are doubtless prompted by aphis movements.—J. R. S. C.

## ELECTRICITY AND VEGETATION.

(Continued from page 330.)

GLASS AND SHADING.—It is a well-known fact that most, if not all, flowering plants under glass do best when situate as close to the glass as practicable, and the reason generally assigned for this is that they are thus brought nearer to the light. But this is not altogether the correct explanation: it is not so much the light itself as certain results produced by the light upon the glass. There is a small electrical toy obtainable at the toyshops which affords an excellent illustration of what these effects may be. A small shallow box of deal, fitted with a sliding pane of glass for a lid, has inside a number of little figures cut out of thin paper lying loose upon the bottom. Now, directly the glass is excited by friction with a piece of leather or flannel, the figures are electrically attracted and start up, jumping and dancing about from the glass to the box until the whole of the electricity shall have been discharged. It is recognised in scientific circles that it is impossible even to lift a single finger without producing electrical disturbance; whilst Judge Grove practically demonstrated at the lecture table that a ray of light falling upon a specially prepared instrument charged it with electricity. Hence it would be utterly impossible that our bellglasses, our framesashes or lights, and our glass roofs, should escape this electrical influence, not only from the action of light, but also from the friction of the wind and every passing current of air.

On placing a bellglass upon a flat surface of earth it at once, by its non-conductivity, separates the enclosed air from that outside, and joins it electrically with the negative state of the earth with which it is in contact. Now, it has been explained that roots

are as a rule produced chiefly under this negative condition, and hence it is that such a covering facilitates and accelerates root-formation and the germination of seeds, &c.; whilst as soon as the green appears it is absolutely necessary to give air, or in other words to restore the confined atmosphere from its negative to its normal positive condition, otherwise the growths become sickly. Let these facts be applied to glass coverings on a larger scale, and the result will be identically the same. On referring to the figures 1, 2, and 3, page 355 of the previous volume, illustrating the chemical effects upon the metal as being greatest at A, fig. 1, where the positive and negative elements meet, we have an analogous proceeding with that occupying the opposite surfaces of the glass—the one positive and the other negative—and hence the nearer to the glass the greater the electrical attraction, and consequently the drawn effects occurring from distance. But this is only one side of the question. By exposure near to the glass the sides and undergrowth of a plant as well as the top are brought under the electrical influence, and thus become induced to form a sturdy and bushy growth instead of the weaklings similar to the too thickly placed seedlings of a seed pan or the too thickly planting of trees in a wood or plantation. Thus theoretically, the lower the glass be extended downwards, and the more open and exposed the situation, the better ought it to succeed. Here, too, we have an explanation of the effect of placing a sheet of glass close over freshly sown seeds either in the open or in pots. The first advantage is, that it keeps up a damp negative atmosphere, and next that it brings the electrical influence close down upon the surface of the soil. In the former case I find that laying a sash-frame down upon the fresh-raked earth, and sowing the seeds within the several compartments made by the impression of the frame, is very much the most successful way of effecting their germination.

These facts lead us to the consideration of a most important subject which few practical men seem to be agreed upon—namely, the best means of shading and the extent to which it can be most satisfactorily resorted to. It must, however, be understood at the outset that there are two opposite conditions involved in the result of shading, one the weakening of the intensity of the light, the other the lessening of its quantity, but in both cases it is an essential and indispensable point that the chemical and some other properties of the light be not destroyed or deteriorated. A case in point will give a good illustration of the reality of such an occurrence. On one side of a conservatory, in consequence of its being overlooked from the adjoining premises, the glass was kept painted with whiting; but this was rather troublesome from its oft-required renewal, and hence it was suggested that by mixing the whiting with drying oil this might be obviated. It was at once put into practice, and with such a promising appearance that it was had recourse to in several other instances. Putty thinned with raw linseed oil and a little dryer gave the surface much the look of rough sheet glass, and seemed to obstruct but little light, yet the ultimate result was anything but what would have been expected.

Along the entire side so treated extended a shelf filled with large old scarlet Pelargoniums which had occupied the same position for a number of years and had always done well previously, but this spring the greater part of them proved to be dead or dying, and this was at first attributed to the frost; but when a small frame as well as two pots covered by bellglasses similarly duded, the former filled with small plants of Ferns, the others with bulbils, were found to have shared the same fate, it became an irresistible conclusion that it was caused by some deleterious action of the light. But the most remarkable fact remains to be stated. In a small greenhouse devoted chiefly to Roses, but having an 18-inch shelf in front, the first three rows of panes over this had the inside of the glass duded in the same way; and although the seedlings, &c., for the rest of the summer did not do satisfactorily, nothing was thought of it until the succeeding spring on the Roses beginning to break into leaf, when the truth became most incontestably apparent. Two strong shoots of the Cheshunt Hybrid had been carried up to the top of the house; and the singular part is, that on the stem more than 2 feet long under the duded glass there was not a single side shoot, whilst at the commencement of the clear part of the roof the branches began, and now form a dense mass up to the top, every joint having its shoot and bud; but since the glass has been cleaned a few weakly shoots without buds have made their appearance. A few panes of glass immediately over a Triomphe de Rennes previously smeared with common whiting and left so through being inaccessible for the oil has acted without similar results, and is a fair contrast in the effects, whilst it proves that the quality of the light is of infinitely more importance than its quantity or its intensity. Now it is an essential condition that some portion of the glass, how-

ever small, should be left clear and clean, forming interstices between the shading material. This is Nature's principle of shading; for all plants and shrubs growing under trees receive their portion of sunshine through the spaces arising between the leaves and branches, and it is sunshine rather than diffused daylight against which shading is required. Practically, I have found a trellis of laths most effective, and far more satisfactory than any kind of textile fabric. It is considered that a horizontal slit admits more light through it than a vertical one, and certainly my experience leads me to believe it; but when only a moderate degree of obstruction is desired, a diagonal or lozenge-shaped opening gives apparently the best results, otherwise a kind of Venetian blind formed of laths or rods may be made so as to roll up when not required. For a temporary rough shading outside a roof or frame a small quantity of clay, made into a cream with water and sprinkled with a brush or put on with a syringe, is much better than whiting, as the first shower effectually washes it all away, which it does not with the latter; and clean glass I hold to be a desirable point.—W. K. BRIDGMAN.

#### FRUIT HOUSES.

*Vines.*—Late Vines started in February or early March are commencing flowering, and to insure a good set maintain a minimum temperature of 70°, and shake the rods several times a day to distribute the pollen. The best plan, however, is to take pollen from those Vines that afford it abundantly, such as Hamburgs, and apply it with a camel's-hair brush to the stigmas of all shy-setting kinds, such as Muscats. A somewhat lessened supply of atmospheric moisture will, if accompanied with a circulation of warm air, aid the setting. Resort as little as possible to stopping or removing laterals whilst the Vines are in bloom; but as soon as the fruit is set pinch frequently, as it is inadvisable to allow the laterals to extend greatly and afterwards be obliged to remove them in large quantities. During bright weather very little fire heat will be necessary if the houses are closed early, as with sun heat and plenty of atmospheric moisture the temperature may rise to 90° or 95°, which will do more to advance the crop than three times as long firing in dull weather. These remarks only apply to Vines in full growth, as those that have fruit nearly or quite ripe will be better kept cooler. Ventilate early in the morning. Afford copious supplies of tepid water or liquid manure to inside borders where the Grapes are swelling; and for borders where the soil is light and porous water may be necessary, as the rainfall of late has been considerably under the average. If any is supplied it must be at a temperature of 85° to 90°. Where Grapes are ripening maintain a constant circulation of warm rather dry air, but do not entirely withhold moisture, or it is likely the foliage will suffer and be attacked by red spider. There is no better remedy for this pest than painting the hot-water pipes thinly with flowers of sulphur mixed with skim milk. Attend to stopping and tying the Vines in succession houses, allowing no more foliage than can have full exposure to light and air. Vines struck from eyes early in the year and grown in pots or turves may now be planted out, giving a good watering at 95° to 100°, mulching the surface with a couple of inches of short manure, maintaining a humid atmosphere, and affording shade during bright sun until the Vines are established.

*Melons.*—Directly the fruit is cut in the earliest house and the plants are required to give a second crop, cut back the old stems to promising growths at the base. Remove some of the surface soil and supply fresh lumpy loam, watering with weak liquid manure at 90°. Maintain a rather close and moist atmosphere, and if the plants are in good health they will soon produce another crop of fruit. If the old plants are very much enfeebled by carrying the first crop, or if they have been infested with red spider, an entire removal of the old compost must be made, and the house thoroughly cleansed. Beyond covering the rubble over hot-water pipes with turves, only hillocks

or ridges should be formed, and flattened at the top so as to give a depth of soil of 10 inches, and when this is warmed plants may be placed out at 30 to 36 inches distance apart, giving a good supply of water at a temperature of 90°. Train with one stem, not stopping until the plant has run two-thirds the distance allotted to it, and then take out its point. Remove every alternate lateral; if those retained do not show fruit at the second or third joint pinch out their points, and fruit will show freely upon the secondary laterals. Supply water as required to prevent flagging, and maintain a genial condition of the atmosphere by damping available surfaces in the morning, and syringing about 3.30 P.M. Ventilate from 75°, maintaining the temperature at 80° to 85° with sun heat through the day, closing at 80°, but do not allow the temperature to advance much above 90°. When the flowers are expanding discontinue syringing, damping the house in the morning and early afternoon of bright days. When three or four pistillate flowers are expanded fertilise them, stopping the shoots one joint beyond the fruit, and continue this daily until four to six fruits on a plant are set and swelling, then reduce the fruits to the number required: very strong plants may carry six, and proportionately less according to their vigour. Very little growth will be made if the plants have a full crop, but all laterals must be kept closely stopped. Every encouragement must now be given to swelling-off the crop, pursuing the treatment as advised prior to setting, watering occasionally with tepid liquid manure. Support should be given to the fruit in good time, and when ripening has commenced supply water only to prevent flagging, and omit the syringing. The above *résumé* may be useful for those having houses or pits which can be put to this use.

*Cucumbers.*—The nights have been cold, and necessitated the continuance of fires; but the days have been bright, requiring great care in ventilating. Morning syringing is not desirable, but abundant atmospheric moisture must be secured by damping, and the syringing should be done early in the afternoon. Careful attention will require to be given to shading, so as to prevent flagging, and yet employ it no more than is absolutely necessary. Copious supplies of liquid manure will be required, and surface-rooting should be encouraged by removing any loose surface soil and supplying fresh lumpy soil. Remove exhausted growths, stopping the shoots one or two joints beyond the fruit, and thin where necessary to prevent overcrowding. Night coverings will still be necessary for pits and frames, and lining to the sides of the frames, &c., for the maintenance of the top heat. Any frames or pits at liberty may have the beds renovated for young Cucumber plants, which will afford fruit through the summer.

#### PLANT HOUSES.

*Stove.*—*Tabernaemontanas* are growing freely, and should receive more water. These useful flowering plants are often grown in too much heat, as they do not require so much as *Ixoras*. The latter are producing their flowers, and should if required for conservatory decoration be prepared for the change by affording them all the light possible with moderate ventilation. *Bougainvillea glabra* intended for the conservatory should be moved from the stove before the first flowers have attained their full size. *Allamandas* may be employed in a similar manner. Other stove plants intended for conservatory decoration or exhibition should be gradually subjected for a few days to a little lower temperature with plenty of light. Any that have been plunged in bottom heat must be removed from it some weeks before they are taken from the stove, but when required for such purposes or for affording cut flowers the plants ought not to be placed in bottom heat. *Dracenas* grown in quantity for conservatory or room decoration should be transferred to cooler quarters. See that they are kept free of red spider, which is a serious disfigurement to the foliage if its progress is not arrested. Tuberous *Begonias* that were started early and grown on in this structure should also be gradually hardened, similar remarks applying to *Gloxinias*. Seedlings of either of these plants that were sown early should be potted singly, grown on in a genial temperature near the glass with shade from powerful sun, and if well attended to in summer they will make fine decorative plants by autumn. Small specimens of such plants as *Allamandas*, *Bougainvilleas*, *Clerodendrons*, *Gardenias*, and other free-growing plants that were potted early and have filled the pots with roots should be shifted into pots about two sizes larger, accord-

ing to the vigour of the plants and the purpose they are intended for. All twining stove plants and climbers should be examined once a week, so as to keep their young shoots from becoming entangled.

*Celosia pyramidalis* vars. are fine for summer and autumn decoration of the conservatory, and up to the end of the year in warmer quarters. Sow in gentle heat, and pot off the plants obtained singly when large enough; keep them rather close until established, when they will succeed in an intermediate temperature. Pinch out the first flowers, and keep the plants near the glass to induce a sturdy habit. Syringe to keep down red spider. Pots 6 or 7 inches in diameter will be large enough for useful decorative plants. Whenever aphides or thrips are seen the house should be fumigated.

*Ferns.*—Such useful Ferns as *Adiantum cuneatum*, *A. formosum*, *A. pubescens*, *A. gracillimum*, *Pteris serrulata*, *P. umbrosa*, *Lomarias*, &c., may be grown in quantity for the conservatory, decorative purposes, and cutting. Continue potting young plants, which are usually abundant in ferneries and stoves. Place the plants in small pots, and when established let them have a position where they will make stout growth; for though the fronds are paler in colour, if grown in plenty of light they are much more enduring, lasting double the time that those grown in a shaded and close atmosphere do. By attending to potting the seedlings two or three times a year a stock will be maintained of a size suitable for decoration or shifting on. Most Ferns are in active growth, and require frequent and copious supplies of water. Any in small pots for the size of the plants may have liquid manure once a week, and if care be taken to have it clear and weak it will not only improve the size of the fronds but enable a fine growth to be made without increasing the size of the pots. Tree Ferns employed to decorate structures where the temperature is cooler and drier than the fernery must not be removed whilst making the growth, or the fronds will be injured.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

##### KITCHEN GARDEN.

THE cold bright dry weather recently experienced, although unfavourable to the active growth of vegetables, has offered good opportunities for the extermination of all weeds, and thereby saving much labour that would otherwise be necessary. Frequent hoeings, besides destroying weeds, are very beneficial to the advancing crops, and will also to a certain extent prevent the soil cracking. Where the seedling Broccoli, Kales, Savoys, and other similar vegetables have been destroyed by insect pests (and this has happened to two sowings in some localities), it is advisable to sow the remainder of the seed in boxes, and place them in frames or under handlights in the open. The plants thus obtained must be pricked out when in rough leaf and before becoming drawn, choosing showery weather for the operation, and giving the preference to a border the soil of which is fine and light. The plants of this sowing may be pricked out about 4 inches apart each way, and as they can then be lifted with a good ball of earth, not much time will be lost. Treat in the same way any plants that are crowded either in boxes or seed beds.

Peas for the late crops ought now to be sown, Hair's Dwarf Mammoth, Veitch's Perfection, and Premier being suitable varieties. Excellent tall late Peas are *Ne Plus Ultra*, *British Queen*, and *Williams' Emperor of the Marrows*, giving the preference to the first mentioned. In dry localities, or where the soil is poor and thin, it is advisable to prepare trenches as for Celery. These may be 18 inches wide. The first spit of soil being thrown on each side, a liberal quantity of good manure is forked into the bottom spit, half of the first spit is returned to the trench; the whole is then made firm, the seed sown and covered with more of the soil first thrown out. The Peas thus have a greater depth of soil and abundance of manure to root in, and being in a trench can be readily and heavily watered as required. In some gardens by no other means can the attacks of mildew be prevented.

Lettuces ought now to be sown where they are to remain. By sowing frequently on well-enriched ground and thinning early and

freely the plants are less liable to run to seed, besides being of very superior quality. The Paris White Cos or any of its varieties are most suitable.

Plants of Brussels Sprouts and Veitch's Autumn Cauliflowers that were raised under glass and pricked out in the open or in frames should, when of good size, be permanently planted. Both are valuable crops, and the former especially cannot well be put out too early. The Cauliflowers may be planted among the widely planted early Potatoes, but the Sprouts deserve a clear quarter, which should be tolerably rich, deeply dug, and then trodden firm. The rows may be placed 3 feet apart and the plants at least 2 feet asunder in the rows, it being a great mistake to crowd them. When planting any of the Brassicas always render the soil firm about them; they will more readily become established.

If Strawberries have not already been mulched with fresh manure it should no longer be neglected. Finish off with a little clean litter for the fruit to rest on. Where manure or straw cannot be obtained the grass from mowings may be substituted; it, however, rather encourages the depredations of slugs. The plants in newly made beds ought not to be allowed to bear fruit unless they are strong and well established. Rows of excellent Lettuces may be grown between them, and the Strawberries next season will well repay for the self-denial.

#### VINERIES.

Vines in cool houses are now making rapid progress, and will require close attention. Crowding-in the growth and overcropping are mistakes frequently made by amateurs, which not only detracts from the value of the current crop but also gradually impairs the Vine's constitution. If the main rods are evenly furnished with spurs, one lateral only should be retained on each spur, selecting the strongest and pulling out the remainder. If the rods are thick stop the retained laterals one joint beyond the bunches; but if the rods are a good distance apart, say 4 feet, then stop at the second joint beyond the bunches. When the growth has stiffened somewhat will be the time to gradually tie down the laterals to the wires. As there is a danger of these being twisted off, especially if strong and the manipulator inexperienced, it is advisable to delay the final disbud-ding till the tying-down is safely accomplished, which of course gives a second chance. Where the house is not yet furnished the leading growth of the rods must be carefully trained in the required direction, pinching off tendrils and stopping the lateral growths to one joint as required. These leading shoots should not be fruited, and later on it will be advisable in the case of prolific Vines to reduce the number of bunches.

As most of the bedding plants will now be gradually shifted out of these structures the temperature may be increased, which will much benefit the Vines, assist to develop the bunches, and also quicken the growth of any heat-loving plants that may be grown for summer decoration. No very regular temperature can be maintained without fire heat, neither is it necessary. Close the ventilators early, say at 4 P.M., at which time it may be done safely, and freely syringe the floors, walls, and staging, and also the Vines if red spider be troublesome, using perfectly clear and tepid water, and by these means create a warm temperature and humid atmosphere, which will last through the night. On clear mornings open early, or the foliage will be burnt. Open when the thermometer has run up to near 70°, and only admit sufficient air to keep it near to that temperature. The roots must not be neglected, as so much depends on them. Inside borders especially require frequent and heavy watering, as well as a mulching of half-decayed manure. The latter should be given to the outside borders, where it will serve to enrich the soil, besides encouraging surface-rooting. If considered unsightly lightly cover with garden soil. These borders ought not to be occupied with either flowers or vegetables, all these tending to drive the Vine roots down into the border—a very frequent cause of the fruit shanking, especially when the borders are badly drained. If conspicuously situated an edging of either Verbenas or Petunias will help to relieve the bare appearance of the border, and will not much interfere with administering heavy supplies of liquid manure later in the season.

## THE BEE-KEEPER.

### REMOVING STOCKS AND ARRANGING AN APIARY.

EVERY member of a newly hived natural swarm before starting off in quest of booty carefully notes its position and bearings, flying for some seconds with its head towards the alighting board, and in like manner every young bee as it commences the duties of life outside the hive makes itself acquainted with its position. But this knowledge once gained suffices, and in all subsequent excursions it simply sallies forth, returning with unerring accuracy to the point left. The removal of the hive only two or three paces will often altogether prevent the finding of it, when the insects fly helpless, homeless, and lost around the too-well remembered spot to die. This power which the bee possesses of imprinting locality upon its little brain (cephalic ganglion) is essential to its well-being, as in normal conditions the proper hive must be entered or the life of the mistaking intruder would pay the forfeit. But the bee-keeper is sometimes forced as a consequence to allow notions of order and symmetry to continue to be violated, for in some circumstances we know of no certain means by which stocks can be arranged without inconvenience and loss; but on the other hand there are conditions which being observed make the operation safe, although the attached trouble is often considerable. Let us first, then, endeavour to explain the best plans for moving hives, and then point out the principles which should guide us in placing them.

As regards moving stocks, the case which presents the least difficulty is that in which a removal of a short distance may be accomplished in stages. If several stocks stand upon the front edge of a lawn, and it is desired to place them at the back of it, all in the evening may be drawn 1 or 2 yards nearer to their future resting place. The succeeding day being fine, the bees flying freely will easily find their new position, to which they next day will return to again discover their hives a yard or two on the march, and so by degrees they can be without any loss drawn to the spot of the bee-keeper's selection. If the hives stand in a line the line can only be moved very short stages in the direction of its length, or the second hive would come quite into the position before held by the first, and so on for the rest. Much confusion would certainly follow this, while the encasement of queens from numerous mistakes would be quite likely. If, however, the line of hives were moved backwards, each stock retreating as it were from its own alighting board, then 2 yards at each stage might be ventured on. If many hives stand together in the centre of an open space, so that the insect village is the general guide to the returning foragers, it is clear that all may be moved many yards if only the mutual relations of position be duly preserved.

But it is the rule that re-arrangement cannot be effected in this simple manner. A road, a river, a shrubbery stands between the present and future position, or the change must be made at once; quarter day is arriving, and the bee-keeper's own removal to a new spot not far enough away to prevent the bees coming back necessitates some device for their safety. The only perfectly reliable plan is to send the whole of the colonies to a new position a mile or a mile and a half away, and by leaving them about three weeks, they will probably forget the former station. They may now be brought home and placed like natural swarms wherever we elect; but inconvenience and expense make this plan unacceptable, while every other yet suggested has some drawback. For instance: If in the evening the hives be closed with perforated zinc (taking care that ample ventilation be given), and then placed in a darkened and cool room and allowed to remain three or four days, the bees will become so demoralised by the imprisonment that they will note their position when freed on their new stands and will almost invariably return to them.

Less damage would be caused to the stocks by merely moving them to their new position early in the morning, smoking them well and then driving the skeps, throwing the bees down in the front of their hives on the new stand and letting them run in as a natural swarm. The bees from frame hives would simply be shaken on to a board at their hive door. Before attempting this plan, which is not reported as being with all stocks quite successful, it would be well to gather the hives into little closely placed lots of three or four each, and at the time of removal stand a hive with a comb containing brood on the vacated spot to gather up the stragglers, which may be brought home in the evening and started as a nucleus or swarm according to number. The fright the bees have already experienced in having lost their home will add to their caution, and all, or nearly all, will remain.

A device more simple than any of the foregoing is sometimes quite successful, and consists in placing a wide cover in front of the hive door so as to cut off the daylight within, and yet give the bees entrance and exit between the back face of the cover and the front of the hive. When the bees have become thoroughly accustomed to this, take the stock to its new quarters in the morning, remove the cover, and smoke well. Each bee before leaving the hive learns the entrance of daylight and the general outlook that the stand is changed, and notes the station in consequence. But the principles which should guide us in placing our stocks now demand attention, for undoubtedly the desire to move the bees has often for its origin that love of regularity and trimness which may be most prejudicial to the success of our operations. Some years since I was asked to visit in the south of England an apiary, the property of a wealthy gentleman who had, notwithstanding the advantages of superior appliances, failed to secure results at all equal to those which seemed to fall without effort to his own tenantry, amongst whom, to his great horror, the sulphur-pit reigned supreme as the only means of clearing bees from the honey stocks. The owner, a man apparently of most orderly mind, introduced me to his bees, which were housed in a straight line of hives all precisely alike in shape, size, and colour, faultlessly clean, and arranged upon substantial pedestals with stone tops, all of which were accurately equidistant with about 2 feet interspace. The hives, moreover, were backed by a long regular wall which formed the side of a kitchen garden, while the trees nailed against this seemed especially trimmed to disprove the assertion sometimes made that no two things in nature are alike. In front ran a path wearying by its length and as straight as an arrow. When we first caught sight of the apiary it looked not unlike a huge brown caterpillar, each segment of the body of which was represented by a stock, and I recognised at once some reason for the failure complained of, for had all been devised with an idea of puzzling and confusing the bees the arrangement could have been pronounced perfect. It is obvious enough that the dead similarity in hives and surroundings which I have just described must make the task of each worker in selecting its own proper home so difficult that uniform success in it is not attainable, and as a consequence an unusual and dangerous interchanging of inhabitants amongst the hives is continually going on, which will lead from well-understood causes to robbing and disaster. But the more serious danger is not with the workers but with the young queens. These, when they leave the hive for the purpose of meeting the drone, fly in and out several times and mark the station with great care; but in the circumstances upon which I have animadverted, and indeed in many apiaries, is not the picking-out of the right hive at the return of the expectant mother an exploit almost as difficult as the selection of a given note on the keyboard of a pianoforte? and should the bewildered insect, now the hope and promise of the colony, through our misguided notions enter the wrong hive she is immediately butchered, and the stock to which she belonged must, unless bee-mastership come to the rescue, die out or fall a prey to robbers. Let us, then, avoid long lines of similar hives, unless characteristic landmarks, such as trees or shrubs, rise amongst them. Let variety in colour if not in form come to our aid, and we shall then know less of robbing, while our young queens will not suddenly and mysteriously vanish.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

### THE IRISH COTTAGERS' HIVE.

BEING very much impressed with the novelty of Mr. Lyon's hive for cottagers I endeavoured to construct one with the following results. I obtained two boxes from my grocer, which are sent to this country containing soap; they are made of pine, the sides being over half an inch thick, and the ends are nearly an inch thick; they have a bottom and lid, the joints being secured. One I prepared for a body box and the other for a cover. The hive when finished with the cover on resembles Abbott's "Irish hive," being shed-roofed. The body box holds nine frames and a dummy; I have them on zinc slides, with distance pins, which are shoemaker's brass tacks of the largest size. This only cost me 1s. 2d., but had I paid for all the materials I should have had my hive for 2s. 2d. To encourage others I may say that my hive is superior in utility to some hives that cost 10s. As the frames rest on the ends, the first thing I had to do was to take part of one of the lids to make two pieces to raise the two sides high enough for the zinc slides and frames on the ends, this being done by nailing them on. I nailed the zinc on with shoemaker's rivets, and a very thin piece is nailed on to cover the ends of the frames. These are all of one scantling, being cut out of a half-inch board of clean spruce 8 feet long by 9½ inches wide. This

board only costs 5d. retail. With a lock saw I cut the frames up the centre for comb foundation; I cut a 5-inch slit in the end for entrance, with a 4-inch alight board in the centre, and sloped off at the ends and nailed it to the end. The hive when uncovered has the appearance of one sold by Messrs. Neighbours. The sides project half an inch; the piece to cover the frame ends and the light board is exactly the same shape. The cover is the same size as the body box with plinths all round to go down over; it is the same height at front, but slopes 3 inches at the back, having two bars on the roof made from a part of itself, giving it quite a neat appearance. Two coats of green paint with oak varnish covers and beautifies all.—COMBER, *Co. Down.*

### TRADE CATALOGUES RECEIVED.

James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Plants, including Novelties for 1881 (Illustrated), and List of Bedding Plants.*

William Bull, King's Road, Chelsea.—*List of New and Beautiful Plants (Illustrated).*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Bedding and Border Plants.*

R. Pennell & Son, Lincoln.—*Catalogue of Miscellaneous Plants.*

J. Linden, Ghent, Belgium.—*Illustrated Catalogue of New and Rare Plants.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**Seedling Pansies** (*W. J. M.*).—Although the flowers were sent in a tin box and were packed in moss the latter was quite dry on arrival, and the Pansies were so much shrivelled that it was quite impossible for anyone to form an estimate of their merits. The dried petals of the dark self appear to possess great substance, but as to its form and colour we are wholly without the means of forming an opinion.

**The Gardeners' Royal Benevolent Society** (*J. L. W.*).—The object of the Society is the granting of substantial annuities to gardeners who are incapacitated by age or infirmity from following their vocation, also to widows of gardeners who have been left without means of support. The annuities are granted for life, and many recipients are now enjoying them. The number of annuitants elected yearly depends on the funds at the disposal of the Committee, and a most laudable endeavour is being made to increase those funds. You are quite eligible to become a subscriber and annuitant, and you can obtain all particulars you need by writing to the Secretary, E. R. Cutler, Esq., 14, Tavistock Row, Covent Garden, London.

**Bulbs in Lawn** (*Mrs. Wilks*).—Your gardener is quite right; the lawn must not be moved until the foliage of the Crocuses and Snowdrops shows signs of decay; in fact, it should commence withering before it is cut off. Your display of flowers next year depends wholly on preserving the foliage fresh and healthy as long as possible. To remove it now would seriously weaken the bulbs.

**Warts on Vine Leaves—Grapes Blistered** (*Bishops Waltham*).—Although your general treatment is correct we should admit air earlier, immediately the temperature commences rising in the morning. On some morning, perhaps a Sunday morning, the house has been too long closed, and then too much air has been admitted at once, causing too rapid evaporation from the leaves and fruit. We cannot inform you how often the Vine border should be watered, as this depends so much on the weather; and further, you do not inform us whether the roots are in inside or outside borders. We can only advise you to apply water copiously when it is required, so that every particle of soil is moistened; surface sprinklings are dangerous when applied with the object of conveying moisture to the roots, though not objectionable for promoting a genial atmosphere during the afternoons of bright days.

**Double Daisies** (*M. H.*).—When the flowers "turn single" the fact indicates either poverty of soil or neglect in dividing the plants. After flowering has ceased the plants should be taken up and divided, each portion having two or three crowns, to be planted 6 or 8 inches apart in rows a foot asunder. The soil for the nursery bed so formed should be enriched with manure, and the position cool and shaded, but not the shade afforded by overhanging trees; a border on the north side of a wall or building is very suitable for Daisies in summer. If the soil is sufficiently fertile for growing good Lettuces it will grow the Daisies well. The plants should be watered copiously during hot weather, and the ground kept free from weeds. We have grown thousands of Daisies in the manner described, and have never failed in having strong plants and large double flowers.

**Water Melons** (*A Fourteen-years Subscriber*).—They require practically the same treatment as ordinary Melons, and may be grown in houses or frames. We have grown them successfully by having strong plants ready for planting in May, by which time the frames that had been employed for forcing Potatoes were at liberty. The soil was removed and a few barrowfuls of fermenting materials mixed with the old bed, the soil replaced, and when gently warmed the Melons were planted. They were then watered, pruned, and ventilated as

for ordinary Melons, and in due time fine fruits ripened; but they were not by any means equal in flavour to the best named varieties of Melons grown under precisely the same treatment. If seeds are sown at once in heat, and strong plants raised ready for planting in frames about the middle of June, you may with good cultural attention expect fruit in the autumn. You cannot expect a satisfactory crop in the open ground in your district.

**Flower Garden Plans** (*R. Parker*).—Some numbers of this Journal containing plans have been forwarded to you. Further information with additional plans are contained in the Manual of Flower Gardening, published at this office, price 4d., or post free 4½d.

**Raising Bulbs from Seeds** (*A. K.*).—Prepare some light sandy soil and place it in well-drained pots or pans, which should be plunged in moderate heat under bell-glasses or a small propagating frame after the seeds have been sown. Do not allow the soil to become dry, and on the other hand supply water judiciously, as the seeds are very liable to decay in too much moisture. The time that will elapse before the plants produce flowers depends so much upon the treatment they receive that it cannot be determined; it may vary from two to four years. But the chief point is to secure the thorough maturation of the bulbs each season after growth is completed; this should be effected by withholding water and freely exposing the plants to the sun.

**Tacsonia not Flowering** (*W. M.*).—As you say the plant is in excellent health the non-production of flowers may be due to excessive luxuriance. Thin the plant out well, shortening all the strongest shoots, and if you have been supplying liquid manure discontinue the practice for a time, only affording sufficient water to prevent the leaves drooping. Is the position the plant occupies too shaded or damp? Plants raised from seed do not flower so freely as those raised from cuttings.

**Peach Growths Injured** (*A. Young Gardener*).—Assuming that all the trees are in the same house and border, we are unable to account for the injury to the growths of one tree except on the supposition that there are lenses in the glass and the growths have been scorched by the sun; or if this is not the cause of the injury, it may be the result of a deficiency of calcareous matter in the soil. The remedy for this is to remove a good portion of the existing soil and add fresh loam containing a sixth part of lime rubbish or chalk, the soil to be made very firm. The growth would then be more short-jointed and firmer than appears to be the case at present, and the tree would be in a better bearing state.

**Heating** (*W. F.*).—We think you have misapprehended the nature and object of the system to which you refer, and of which you do not state you have had practical experience. For certain purposes of heating it is excellent, for others it is not needed. No form of apparatus is the best for all purposes and positions. We will make inquiries respecting the other mode of heating to which you refer, and possibly inspect it, the excellent horticulturist whom you name being well known to us.

**See-ling Gloxinias** (*H. B.*).—The superior forms of Gloxinias that are now certificated by the leading authorities are so fine that many that are sent us as good from different parts of the country are small and inferior in comparison; yours, however, do not come under this category, for the flowers are large, of good substance, and the colours are pleasing. But although we pronounce the varieties worthy of preservation, we doubt if certificates would be awarded to any of them by the Floral Committee of the Royal Horticultural Society; still your flowers are very good.

**Polyanthuses** (*W. C.*).—The flowers you have sent represent a great variety of double and single forms, most of which are effective border flowers, while some are more curious than beautiful. The laced flowers have a rather clouded appearance, the colours not being defined with sufficient clearness to meet the approval of advanced florists. The double Primrose is very similar to one that was certificated last week, and is a good variety.

**Seedling Pelargonium** (*T. Canary*).—A single pip and leaf are quite insufficient for forming an estimate of the merits of a Zonal Pelargonium, the habit of the plant, size of trusses, and freedom of flowering being essential properties that a variety must possess to be regarded as superior. All we can say is, the colour of your flower is rich and the petals well formed and of good substance, but we are acquainted with varieties similar in colour, although yours may be distinct from them.

**Origin of Pelargonium Mrs. Pollock** (*J. S. B.*).—This beautiful Tricolor Pelargonium is one of the many seedlings that have been raised by Mr. P. Grieve, who gives 1858 as the date when Mrs. Pollock was obtained, and he thus described the parentage of the variety in the issue of this Journal of May 9th, 1867:—"The seed-bearing parent of Mrs. Pollock was a variety called Emperor of the French, and the pollen parent Gold Pheasant. The seed parent of Gold Pheasant was also Emperor of the French, and the pollen parent Golden Tom Thumb. The seed parent of Golden Tom Thumb was an old variety called Cottage Maid, and the pollen parent Golden Chain. The seed parent of Emperor of the French was Cerise Unique, and the pollen parent was Attraction. The result of this cross was three distinct varieties produced on one plant—viz., Emperor of the French, Empress of the French (a marbled-stemmed variety like Cerise Unique), and the Silver Tricolor variety called Rainbow." It may be further mentioned that the varieties Cerise Unique and Attraction were raised by Mr. Kinghorn, and the latter is said to have been the first Silver Tricolor Pelargonium produced.

**Plants Unhealthy—Select Varieties** (*Pelargonium*).—Had you sent us a portion of one of the stems that "turn black" it would have enabled us to arrive at some conclusion on the matter; at present we are absolutely without any data to guide us in forming an opinion as to the cause of injury. The Calceolarias of which the "lower leaves turn soft" have received a check at the roots, probably by neglect in watering, or perhaps improper watering. We have seen many plants similar to yours that have been regularly watered; but the very regularity of watering has been deceptive, for while the surface soil has been moist enough that at the bottom of the pots has been dry. This is a greater source of failure than perhaps any other operation in the routine of plant culture. The soil in which Calceolarias are growing must always be moist, and the plants usually thrive much better when the pots are stood on slates or moist ashes than on the dry shelves of a stage. *Hoya carnosa* will grow and flower well in a greenhouse where the temperature during the winter does not fall below 45°. Let your plant have all the sun possible, keep the foliage clean, and water freely yet judiciously until the middle of August, when the supply should be gradually reduced, keeping the soil comparatively dry, yet by no means dust dry, throughout the winter. Hexagon netting placed over the ventilators will exclude many sooty particles that are injurious to plants, and will not materially prevent the admission of fresh air. You will find it advantageous to use the syringe regularly in keeping the foliage clean, and

without cleanliness your plants cannot be kept healthy. *Six Good Show Pelargoniums* are—Cicely, Artist, Purple Gem, Ruth, Prince Leopold, and Charles Turner; *Six Decorative Varieties*—Duchess of Bedford, Mermerus, Dr. Masters, Queen Victoria, Rubens, and Beauty of Oxtou; *Zonals*—Commander-in-Chief, Livingstone, Henry Jacoby, Miss Hamilton, Fanny Catlin, and Jeanne d'Arc. *Fuchsias*—Lord Falmonth, Model, Improvement, Beauty of Trowbridge, Avalanche, and Mrs. Cannell.

**Names of Plants** (*W. M.*).—The pink flower is *Anomatheca cruenta*; the orange flower is *Diplacus glutinosus*, and the yellow flower is a *Verbascum*, but the fragments were insufficient to enable the specific name to be determined. (*Jones & Son*).—Very much withered, but it is probably *Phlox subulata*. (*E. E. W.*).—*Euphorbia amygdaloides*. If you only want a handbook of the British flora there is a cheap and reliable work published at this office which would suit you. It is *The Handbook of British Plants*, by Notcutt, price 3s. 6d.; and if you add to this Bentham's *Illustrations of the British Flora* you will find figures of the several plants that are referred to in the other work. Bentham's book is published by Lovell Reeve, and is not costly. If you require a work with coloured illustrations the one you name will answer your purpose. (*S. B. & T. H.*).—Orchid flowers require very careful packing, as they are not only very liable to shrivel but are frequently crushed in transit through the post. A small tin box with a little damp moss as a packing medium would insure the blooms arriving in a recognisable condition, but match boxes and others made of thin cardboard are quite useless. (*A Reader*).—1, *Doronicum caucasicum*; 2, *Ruscus racemosus*. (*G. G.*).—1, insufficient; 2, *Pyrus amygdaliformis*; 3, *Symphoricarpos racemosus*. (*B. J.*).—*Oncidium concolor*.

**Removing Stocks** (*H. B.*).—You will find the information you require in an article published in the present issue.

**Hive Construction, Cork-packed Hives, &c.** (*N. Howitt, Croydon*).—The query you submit respecting hive construction shall receive early attention, but it cannot be answered usefully without three or four woodcuts. Careful reading of the article in our issue of March 24th will give you much that you require, while Mr. Cheshire will be happy to show you cork-packed hives at his apiary if you previously make an appointment with him, but Mr. Cheshire does not deal in hives as some of our correspondents have erroneously supposed. The super tray or rack requires covering with some non-conductive cover, but cork packing would be here alike inconvenient and unnecessary. It is not only possible to keep hives as warm with distance tacks as with broad shoulders, but broad shoulders render it impossible to make the hive so non-conductive as with enclosed frame ends. The ease of manipulation is greatly against the broad-shouldered frames, as such cannot be moved without a most irritating wrench and jar which does much to set the bees about the operator's ears. Your last query is practically answered in a reply to another correspondent in this issue, which see.

**Flat-bottomed Foundation—Feeding Bees with Honey** (*H. F.*).—The maker to whom you refer supplies a foundation in which the two faces are not kept in mutual relation. Feeding with honey which has been removed by the extractor in order that sections may be filled will not pay, with one exception—viz., if you have at the close of the season a residue of sections unfinished, and which cannot be finished unless feeding be resorted to, it will pay to feed extracted honey to get them capped and in condition for the market. Of course in this case break up the comb of the sections (as they cannot satisfactorily be kept through the winter), and so bring down the value of their contents to that of extracted honey, or extract from store combs and market your comb honey. Although clearly the latter course here is the right one, yet the waste is so considerable that for bulk the sale of the extracted honey as such is the more remunerative.

**Section Boxes in Rear of Hive—Frame Across Entrance—Sections for Woodbury Frame** (*Idem*).—We do not use sections in rear of hive except where the frames are hung across the entrance, and even then we think the greatly increased labour of the plan is in no way compensated. The most advanced and largest honey producers of America are very much of the same opinion. Comb is perhaps built more quickly at the rear of the hive, but it is not so promptly capped, while it is much more liable to be stained by pollen. We have frames across the entrance in some of our hives. We think it assists weak lots in winter, but it increases the risk from robbing. Six of the 1 lb. section boxes 4½ each way would fit a hive taking Woodbury frames.

**Foul Brood—Space Between Frames and Bottom Board of Hive** (*D.*).—Foul brood may exist in a hive without causing any very strong smell to be emitted. In its earlier stages the smell is often of an acid character, because there is probably present in the saccharine matter fed to the grubs that kind of fermentation known as lactic, by which lactic acid, the acid of sour milk, is produced. As the disease progresses decomposition of the bodies of the larvae gives origin to a smell more akin to that of ordinary putrefaction, faint and nauseous, and quite unlike the odour of a healthy stock. The only certain guide is to examine the combs, when, if many covers of brood cells are found pierced irregularly, while here and there the brownish residue of decayed grubs is seen, you have the evidence of the advanced condition of the pest. This subject has been fully treated in back numbers. Consult those of June 26th, October 2nd and 9th, 1880. No book has, so far as we know, been written by Mr. Abbott. We suppose you refer to "Modern Bee-keeping," the author of which is Mr. Cheshire, who wrote it gratuitously for the Bee-keepers' Association, especially to assist cottagers. Bees when crowded build comb in any space which approaches three-eighths of an inch, while in less than a quarter of an inch they are likely to insert propolis to stop the gap. Distances standing between these the bees leave open and use as passage way. The bottom bar of frames should therefore be a full quarter from the floorboard, which gives the bees ample room, as they can pass through three-sixteenths easily, while openings of five-thirty-two inch will not stop them.

**Removing a Section Tray—Handling Bees—"Doubling"** (*Buzz*).—A super or section tray or rack may be removed during the time of its filling without much inconvenience; and if the space allowed to the queen at the time the supers were put on was not sufficient to keep her going, it may be very wise to make the attempt in order to add one or two empty combs or sheets of foundation in the hive centre. This is one of the most reliable means of stopping swarming. You ask whether handling bees tends to improve their temper. The answer as we take it must depend upon the nature of the handling. If bees are so interfered with as to vex them sorely we imagine that handling makes them the more irritable. Quinby says that he has experienced that dosing with tobacco smoke makes them resent every new interference the more savagely; while Langstroth declares that opening a hive and sprinkling with syrup will, if persevered in, cause them to accept the hive opening as the prelude to a sweet shower, which they await with the gratitude which is said to be a sense of favours to come. This just accords with our experience. Our own bees are

scarcely ever angry. Yesterday we made an artificial swarm, shaking all the bees from their combs, inserted a queen from a nucleus, and reseeded the stock from another without any bees making any attempt upon our fingers, which we never cover. We lift the combs without jar and move quite gently amongst them. If they show temper we with smoker in hand tell them we are master, and go on quietly as before. We often wear a veil when operating amongst our hives, as they stand closely and bees are likely to get down the neck. Doubling consists in shaking a swarm of all the bees from some stock and placing all the combs of brood in an upper storey—i.e., a second hive without floorboard, which is now put over a strong colony. The bees hatch out and give the stock, which now possesses the progeny of two queens, an enormous population. They made the upper hive their super. Its combs are tough, as they have been used for breeding, and are therefore admirably adapted for the extractor. In fine seasons and good districts immense yields have in this way been obtained. A knowledge of the locality so far as the exact time of its greatest honey glut is desirable, as this should determine the best moment for doubling. In districts where Limes and Clover are found even in moderate quantity the harvests may be said to be two—May and the beginning of June (orchard and fruit crop honey), and early in July to near its end. Where Heather is found the flow continues till far into September. The doubling should be so timed as to get the brood hatched by the time extracting should begin. Two or three brood combs from three or four stocks may be taken instead of all from one if it be preferred.

## COVENT GARDEN MARKET.—MAY 18.

TRADE during the week and prices have been well maintained all round.

## POULTRY AND PIGEON CHRONICLE.

## CHANNEL ISLAND CATTLE.

As each of the Channel Islands export a large number of dairy cattle it is very important that each of these breeds, called by the name of the island in which they are reared, should be known not only by name but also by certain characteristics of form, colour, and milking capacity. In fact, we readily acknowledge the value of being enabled to discern the many points which are said to characterise the perfect animal; but who is to detect the excellencies, which we readily admit have been wisely acknowledged by the recording of pedigree or their absence? Very few buyers indeed can understand and are able to detect the various points of a choice and valuable Jersey cow. It is, however, a matter of great consequence to buyers of dairy cattle that they should have a direct way of obtaining the animals required without being subject to the statements only of interested dealers in or agents who purchase cattle on commission. Having acted in the latter capacity for many years we have constantly witnessed the ignorance and total inability of buyers in general to understand the points of excellence in the kind of animals they are seeking. Buyers, however, need not be afraid of being deceived if they will use ordinary care and caution by dealing only with the

importer, who will give a written record of the pedigree from the "Herd-book of Jersey Cattle." But what is better than buying of the importer is to purchase at the sales by auction Jersey cattle whose pedigree has been recorded ever since the commencement, the first volume of the "Herd-book" having been published in 1873.

There ought to be no risk in buying at auction animals of guaranteed pedigree bred in this country, and one advantage of so doing is that the animals bred here are inured to the soil and climate whereon they are reared. This leads to a very important point, inasmuch that all newly imported animals suffer in health and constitution more or less during the first year, but this difficulty may be much modified by careful management. The only way for the animals to continue in health and well-doing, and maintain their condition and milking capacity, is that they should be housed in a roomy box about 10 feet by 12 feet at night in spring and autumn, and entirely in winter, except an airing, when the boxes are fresh littered or earthed. We shall not here, however, extend our observations upon the management, having fully explained our system of housing which we recommend for dairy cattle in this Journal on September 16th, 23rd, and 30th, 1880; pages 270, 294, and 314.

The Channel Island cattle consist of Jerseys, Alderneys, and Guernseys; the former and the latter are the breeds chiefly imported. The number of Alderneys bred on the island is very small, and scarcely over one hundred are imported annually into this country. They may be said to be in most respects a modified form of the Guernsey, having been so much lately influenced by the use of Guernsey bulls, which they very much resemble both in form, colour, and richness of milk. The difference between the Jersey and the Guernsey has become very much more marked of late years, particularly in the head, horns, and nose. The Jersey is by far the smaller animal, finer in the bone, and neat in its general appearance. The horns are short and thin, being also more curled or crumpled; the face is finer, with a more docile countenance. The colours which prevail are the silver-grey and the fawn; in fact, these were the colours which prevailed at the London Dairy Show in October last, and it is fashionable now to breed them of a solid colour, the nose and muzzle being black, and surrounded by a mealy-coloured rim. These must be understood as the chief characteristics of the Jersey and the Guernsey; the latter having usually a flesh-coloured nose, and the colour of the body is nearly always marked with patches of white upon a lemon or light red colour. The Alderneys are sometimes black and white, but the pure-bred Guernseys are never so coloured. The Guernseys are also so much larger and coarser in their frame, and generally they carry more flesh, so that when fattened they arrive at a considerable weight—one-third more at least than the Jerseys under the like circumstances of fattening. With respect to other characteristics the Jerseys, since the "Herd-book" has been compiled, have assumed a self colour, an evenness of outline, and in most instances the tongue is required to be black, more particularly in the bulls and the silver-grey cows. We fail to see the point of this, for beyond fashion and a necessity of such a distinction we cannot see the advantage of insisting upon either of the latter points. We are induced to object to them in some instances, for it affects not only the colour of the hair, but the skin and its surface as well, and in these we do not find the yellow colour or scurf of the skin, so characteristic of the capacity of the animal to produce the richest cream and milk.

In regard to the quantity of milk yielded by the different breeds we by no means agree with Mr. John Thornton, who in the late essay, which has just appeared in the "Journal of the Royal Agricultural Society," wherein he says, "The yield of milk, too, is larger in the Guernsey, yet there is little if any difference in the

yield of butter; indeed, some contend that the Jersey will yield more butter." This is not quite satisfactory, when we state from our experience of more than fifty years, and from the general opinion of practical dairymen also, that the Guernsey cow gives less milk in quantity, but extremely rich in cream as compared with the Jersey, the latter giving a larger quantity of milk, yielding far less cream in proportion. In our opinion the error in this case is mistaking the Alderney produce in milk and cream for that of the Guernsey, for it is notorious that the Alderney cows will often give large yields both of milk and butter also, whereas the Guernsey are famous only for the immense yield of butter in proportion to the quantity of milk, and their disposition to carry flesh whilst milking, and fattening readily when dry or barren.

Although we have recommended farmers to purchase pedigree stock, still we prefer to purchase at auctions, because there is generally a record of both bulls or cows when they are descendants of extraordinary milking animals; but not so in the "Herd-book of Jersey Cattle," which simply records the produce of certain cows and bulls. They give no assistance whatever to the uninitiated in discovering the merit or defect of the animal recorded. We have recently inspected some imported Channel Island cattle just arrived; they were in three separate divisions—some Guernseys, some Jerseys, and a few Alderneys, each division containing individual heifers of great merit. One Jersey heifer, however, was beneath the average appearance in outline and correctness of form; but upon examination we pronounced her certainly the most promising as a future dairy cow, and we were immediately informed that she had just been sold to one of our best breeders and judges of Jersey cattle. In this animal we particularly recognised a point which we always insist upon as a necessary accompaniment of first-rate milking capacity—that of a thin spare shoulder top, and a narrow span on the back close behind the shoulder. There is another point which is fast gaining adherents as to its being a guide to good milking quality, and it is concluded that from the ways and forms in which the reversed hair above the back of the udder, now called the escutcheon, grew in these parts, that the good or bad milking properties of animals might be ascertained, even before they calved. We do not, however, consider this as any guide to an ordinary purchaser or dairyman, because even breeders and judges are obliged to study the matter in various ways before they can become qualified to judge by it. It may, therefore, prove a great deception if attempted by the uninitiated.

#### WORK ON THE HOME FARM.

*Horse Labour.*—Horses have lately been continued with good effect on the tillage of the land, not only in finishing off and drilling-in the Mangold seed, and in some cases the Swede seed, but also in the preparation of the land for the various root crops to be seeded later in the season. Only careless or incompetent managers can have Couch left on the fallows for roots, &c., this season. We find that wherever steam power was used at the early period, or, indeed, where the horse power is equal to the work required for all the preparations for root crops and fallowing work for all purposes, it is in a very forward state. Upon the heavy land farms, which have suffered so much on account of several unfavourable seasons, the fallowing ought now to be in a forward state if the plough has been constantly at work. In a dry time, such as we have lately experienced, the strong soils need not be dragged or worked fine by harrows or roller; because if the land is kept rough so much the better, as the weeds are sure to die, and the land will be thoroughly dried and can be worked fine whenever a sufficiency of rain occurs—in fact, after heavy land has been once thoroughly dried in the fallowing process it gives the best promise of future productiveness, especially for the Wheat crop to be sown next autumn. When we refer to the summer management of the root land it is a very different matter, for in that case we should not allow the land to become too dry; for where the land has been cleaned in March and April, then during the May month it should either be seeded for root crops or kept in a fine and moist condition. If the usual growth of weeds appear let the land be scarified and harrowed to destroy them, but not ploughed, because ploughing allows the precious moisture to evaporate and escape. This mode of treatment, even if the season should change to wet weather, as it did last year during the haying season, the plan recommended will be found to be correct. In case any Couch grass is left in the land

after the last ploughing it should not be ploughed again on that account, for we have now a patent self-lifting harrow, which will most effectually comb out the Couch without losing the moisture of the land. Again, in ploughing the Rye stubbles, or after any green crop, the ploughing and working down by harrowing and rolling should all be done simultaneously, and this may also include the drilling of the seed, which must be done as fast as the land is ready during the day. Upon small occupations, or those of several hundred acres, the one-horse drill is very useful indeed, for it will seed the land as fast as many horses' labour will get it ready, and secure the vegetation of the seed in the driest weather if the land is light and free-working.

*Hand Labour.*—At this time of year a man's labour will be continually required to go with the odd horse or horses, for in those cases where much fodder in the green state is supplied to cattle, it should be the work of one man to cut and of another to cart away the Trifolium, Vetches, Clover, or other green crops, such as Lucerne or even meadow grass which may be required for fattening cattle, dairy cows, or any stock in the boxes. We think it desirable, and it has been our own practice for many years, to employ the man who cuts green crops for other stock to cut that also which may be required for the cart horses. It is customary on some farms for the teamsmen to use the scythe and cut all the green fodder required for their horses, but we strongly object to it, as it is too often made the excuse for shortening the horse labour; and it is of special consequence when the horses are required to make a long day or days for completing any important operation within a given time. Live stock will now require a frequent change from grass land to the green crops upon arable land; and grass land should not be fed off too closely, as that paralyses the after growth. It is, however, another matter if the grass is grazed by the dairy cows in irrigated meadows, for in that case it cannot be grazed too closely, and then irrigated for a future crop, either of hay or after feeding. This brings us to the point of considering the importance of cutting grass for hay, especially if it is required for sheep or lambs. If for the latter the earlier the grass is cut and the finer and softer the herbage is the better the hay will be for them, for they under any circumstances cannot eat much in quantity, and therefore it is the more necessary that it should be of the best quality.

#### VARIETIES.

*EGG-EATING.*—We were asked the other day by a friend as to the best cure for egg-eating. We do not know of any certain remedy, but unless the habit be of long standing the following plans may be tried with a fair prospect of success. Boil some eggs hard, scoop out nearly all the inside, fill up with a mixture of mustard and the hottest red pepper you can get, and place these sham eggs in the nests. The culprits will eat them up, and probably conclude that eggs are not so nice as they thought. Or procure some delf nest eggs and shut the egg-eater up in a coop with them, when she will spend all her time in trying ineffectually to eat the sham eggs and thus get tired of the business. Keeping the laying nests very dark, and seeing that the hens have plenty of lime rubbish to peck at, also sometimes aid a cure. If none of these methods succeed, and the hen is not valuable, it is best to kill her before she teaches her companions the bad habit. If the hen be valuable, a nest with a sloping false bottom made in such a way that the egg as soon as laid rolls under the false bottom of the nest out of reach of the hen may be used. The nest is padded so that the egg may sustain no injury, and a nest egg fixed on the false bottom completes the arrangement.

— *THE HATCHING SEASON.*—We hear various accounts of the results of the season's work. Some of our friends, and we regret to say that they are the majority, have doleful tales to tell of their want of success. From hens and incubators alike the return in chickens has been but a small per-centage of the eggs set. Others again are more fortunate, and some few have had extraordinarily successful results. We shall be glad to hear from others of our readers how they have fared.

— *LORD BEACONSFIELD'S PEACOCKS.*—The two favourite Peacocks of the late Lord Beaconsfield were sent on Saturday last from Hughenden Manor to the Queen at Windsor Castle by Her Majesty's desire. After their arrival Her Majesty, Princess Beatrice, and Prince Leopold drove to the Royal aviary to see the birds.

— *AGRICULTURE IN IRELAND.*—We are informed that agricultural prospects have improved greatly within the last two or three days. Heavy showers, with intervals of warm and brilliant sunshine, fell on Saturday and Sunday, and the result has been to give a great stimulus to vegetation. The cereal crops look healthy, but will

probably be later than in average seasons—a remark which applies also, but with still greater force, to the Potato crop.

— **AN ESTIMATE OF AGRICULTURE.**—Agriculture, says the "American Cultivator," is an occupation which can be so contracted as to make the farmer a mere machine, or it can be so expanded as to make him one of the greatest and most intelligent of his race. Pursued as it was in former years, a toil of degraded drudgery, we cannot consider it strange that the farmer was placed at the bottom of the ladder among his fellow men, and that he should have been considered hopelessly unprogressive. But the agriculture of to-day is one of the most intellectual avocations of man; it ennobles and enlarges the intellect as no industry can. The science of agriculture embraces every other science, and the logic of events in connection with the growing and ripening of crops trains the mind to a system of reasoning which cannot be surpassed in many of the professions. In our halls of legislation we hear the pleas of the lawyer, the oratory of the man of letters, yet the arguments of both are frequently demolished by the plain solid common sense of the sturdy farmer. What a pity it is that we do not have more of the latter class of wisdom at our State and national capitals!

— **DAIRY FARMING.**—An imposing array of noble names appears on the prospectus of an association for promoting a knowledge of dairy farms. By means of a limited company it is proposed to buy land, establish a dairy farm and school, and by first-rate tuition inculcate profitable methods of dairy farming in this country. Farmers' sons and others are to be received as apprentices. The concern, it is hoped, will be self-supporting, but the mainspring of the scheme seems to be a desire to improve the profits of English farms. Philanthropy, however, cannot be said to be the only motive, for the vice-presidents whose names appear are landlords; and what improves the condition of farmers can but be of advantage to those to whom farmers pay rent.

— **DEATH OF MR. TOWARD OF OSBORNE.**—Sir John Cowell, by command of the Queen, attended the funeral of the late Mr. Andrew Toward, which took place at Whippingham Church last Thursday. Mr. Toward was for thirty-nine years land steward at Osborne to the Queen and Prince Consort, by whom his long and faithful services were highly valued. He had, under the direction of the Prince Consort, executed the entire laying-out of the grounds, gardens, roads, and plantations at Osborne. He was universally respected, and died in his 87th year at Amherst Lodge, Carisbrook, where Her Majesty had repeatedly visited him, and saw him last two days before she left Osborne. Mr. Toward had been for many years at Bagshot in the service of the late Duke and Duchess of Gloucester.

— **EMIGRATION TO AMERICA.**—A recent telegram from New York states that 6521 immigrants landed there on the 10th instant, the largest number ever received in one day in May. The number landed last week was 16,841, making about 130,000 since January 1st. The Immigration Office is taxed to its utmost capacity, and is unable to furnish the classification of nationalities. A rough estimate places the proportion of Irish at about one-tenth. There is a brisk demand for labour in all parts of the country, and the demand for farm labourers exceeds the supply.

## POULTRY AND PIGEONS

### PRACTICAL SCIENTIFIC BREEDING.

GENERAL PRINCIPLES.

(Continued from page 389.)

A QUESTION often asked by beginners in the poultry yard is this, "How many hens should be allowed to run with each cock?" It is a question which is more easily asked than answered. So much depends upon the season of the year, the age and vitality of the birds, the size of the run, and the particular breed kept, that anything like a general answer is very difficult to frame. It is, however, a matter of such importance that it cannot be overlooked, and we shall endeavour to be as explicit as possible. For very early hatching—that is to say, for the January and February

chickens, we should under ordinary circumstances allow but two hens to the cock in the more sluggish, and four in the more active breeds. As the season advances the number may be doubled in each case. These rules must, however, be departed from if the male bird be either very vigorous or very old, or if the run be very limited or very large. A valuable old bird should be mated with but one or two pullets, and the number should not be increased as the season advances. A very vigorous bird will require a larger number of hens, or those with him will be injured and there will be a failure of chickens. A very limited space, again, will decrease the vitality of the stock, while an unlimited run will have the contrary effect; and both these points must be taken into consideration, and the number of hens increased or decreased accordingly.

We have known instances at farm houses where as many as forty hens have been running with a couple of cocks, and almost every egg hatched; but then the birds were mere mongrels and had an unlimited run, and we should not recommend that in the case of prize-bred poultry more than fifteen hens should under any circumstances be mated up in one yard.

In selecting a breed young fanciers should bear in mind that in these days of close competition it is necessary that birds should have every reasonable advantage in regard to suitable space and locality. Success is often merely a question as to how far in-breeding can be carried without an undue deterioration of the strain. Fowls which thrive best in a large run can no doubt for some time be bred with fair success in a confined space; but when it comes to be a question how long fresh blood can be dispensed with, the man who has ample space for his birds, and whose locality is most suitable for the breed he keeps, has the immense advantage of being able to keep the vitality of his strain at the highest possible point, and thus carry out his plans to their legitimate end without being forced to cross in some foreign and perhaps undesirable element. Every circumstance of space and locality should be carefully considered. The amount of run available, the aspect, the soil, and the nature of the surface, all have their share in success or failure. Dorkings are not found to thrive on a heavy clay soil. The feather-footed sorts are unsuitable for rough or uneven ground, or for long grass. Game and Hamburgs require ample space. Spanish require warmth and a southern aspect. The list might be increased indefinitely, but these instances are enough for our purpose, which is merely to illustrate the statement that the circumstances of the fancier and the necessities of the breed he selects should as far as possible coincide. Much may be done by care and intelligence to supply artificially what is wanting in natural advantages, but it is useless to handicap oneself in a contest, when by the exercise of reasonable foresight an even start may be secured.

One other matter claims a passing notice as exercising an influence upon the vitality of the strain. Whatever be the breed selected the proper housing of the birds is of primary importance. The essentials in this respect are dryness of ground surface, cleanliness, thorough ventilation, and freedom from extreme cold or draught. Nothing so thoroughly undermines the constitutions of fowls as continual standing about on a damp surface, and confinement at night in a close vitiated atmosphere is almost equally detrimental. The larger the covered houses and sheds are the better it will be for the birds, provided that the above points be attended to; but no amount of house room or shedding will compensate for neglect in these particulars. Roup and liver disease follow in the train of wet floors and deficient ventilation; and even though these evils may not develop at the moment, the seeds of them are sown and they bear fruit in after generations.

(To be continued.)

### PRESERVING FOOT FEATHER.

WE have frequently been asked how the feathers which grow on the legs and feet of Sultans, Cochins, and Brahmas can be kept from breaking or wearing, and assuming that ragged appearance which in the show pen contrasts so badly with more perfect foot feathering. To all who keep or contemplate keeping such fowls the subject is of the greatest importance, as in competition good foot feather is a weighty point. Some people have no difficulty in keeping them perfect, others cannot do it without much preparation and care. The whole matter depends on the run. On a hard rough run the foot feather will never be satisfactory, but with smoothness and softness under foot the feathers will always be good. Heavily feathered feet are much more easily kept in condition than scantily furnished feet, and as much feather is the proper thing attention should be devoted to breeding for it. Sand or very fine gravel makes an excellent run for feather-footed fowls, and short grass is equally good.

Sawdust may also be used, but ashes, unless in a very fine powdery state, are bad, as rough sharp ashes cut the feathers quickly. In small confined runs the sand, or whatever may be used, should be 4 inches or more in depth, and it should always be kept loose on the surface. Cleanliness is very desirable in such places. When the droppings adhere to the feathers they soon cling together and form a hard mat, and when in this state they are most easily broken. For this reason fowls in confinement should have their feathers looked to occasionally to guard against accumulation of the kind.

Many will now be beginning to look to the foot feathering of their chickens intended for the autumn exhibitions, and the main thing with them is to have a soft run. Apart from this there is no artificial way of keeping the feathers perfect, but in the kind of run we have indicated they will grow quickly without much danger of being damaged.

Perhaps it may be well to point out that show fowls of these breeds have not the feet feathers always in exhibition trim; but when there are no shows on they are often allowed to run rough, and they are only put on their soft walk a few weeks before being shown, and if there are any broken quills they are generally drawn out to give place to a fresh batch of quick-growing young feathers. Dorkings with gouty feet and feather-legged fowls do well on the same kind of run, softness of the run being advantageous in both cases.—J. MUIR.

#### AMERICAN TURKEYS.

THE Standard recognises six different varieties—the Bronze, Narragansett, White, Black, Buff, and Slate. All of these originated from the North American wild Turkey, and all possess valuable qualities; but on account of its great size the Mammoth Bronze is perhaps the most profitable variety to raise for market. Well-grown males of this variety will weigh from 18 to 22 lbs. alive when six months old, and the hens from 10 to 14 lbs. at the same age. The Bronze Turkeys do not reach maturity until the third year, and we frequently see adult gobblers that weigh anywhere from 35 to 45 lbs., and adult hens that weigh from 18 to 25 lbs.

The main colour of the plumage of the thoroughbred Bronze Turkey is a dark bronze that looks almost black in the shade, but in the sunlight the back and breast glitter like burnished gold. Each feather on the back terminates in a narrow black band which extends across the end. The wing feathers are pencilled evenly across with bars of white or grey, and when the wings are closed the wing-coverts form a broad bronze band. The tail feathers are black, pencilled across with narrow bands of light brown, each feather ending with a broad black band, with an edging of white or grey. Legs are large and strong, dark in young birds, but approaching a pink or flesh colour in adult birds. The hen closely resembles the gobbler, except that the plumage is not so brilliant, and the feathers generally have an edging of white or grey; clear brown or black wings; back of tail clear brown, black, or grey. White feathers in any part of the plumage are counted as disqualifications, and no honest breeder will sell such birds for breeding stock.

The White Turkey, generally called by breeders the White Holland, is not so common as the Bronze variety, and has not yet received the attention at the hands of breeders that its merits demand. The White is not so large as the Bronze variety, but I am inclined to think that this is more the fault of breeders than of the breed. M. T. Kelly of Bloomingdale, Ind., once owned a pair of White Holland Turkeys that were hatched on the first day of July, 1873, and on the first day of December, 1874, weighed 63 lbs. This shows what skill in breeding will do. I am confident that if breeders would take the same pains with the White that they have with the Bronze variety, such weights would not be exceptional.

As table fowls I certainly think that the White Hollands are superior to any other variety. Their flesh is whiter, more tender and juicy, and they look more tempting when dressed than the dark birds. Some breeders claim that the dark-coloured birds are hardier than the white, but such has not been my experience. Other breeders claim that the White Hollands are not so much disposed to ramble as the Bronze, but I never could see much difference in this respect. Turkeys are Turkeys, and so long as any of the wild Turkey nature remains in them they will wander and hide their nests.

The entire plumage of the White Holland Turkey is of a clear snowy white, and this, contrasting beautifully with the rich scarlet of the head and the jet black beard of the male, renders it an object of attraction in the show room and in the poultry yard.

The Narragansett is an old and a popular variety wherever its merits are known. In Southern New England this variety is raised extensively for home consumption and for the city markets. Of late years farmers have crossed this breed with the Bronze, until now these cross-bred birds rival the Bronze in size.

The Narragansetts are generally called a grey bird, but when thoroughbred they should be of a metallic black, each feather ending in a broad, light steel-grey band. Carelessness in breeding has "mixed" the plumage so that in many flocks the feathering is uneven, or splashed with black or white, but they can be bred true to feather. These birds of mixed plumage are not standard birds, and if one cares for looks I should not advise breeding from them.

The Black, Buff, and Slate are smaller varieties than either of those that I have described, and need no particular description, as the name sufficiently indicates the colour. The Slate is sometimes called the "blue" Turkey, and, barring the size, is a good variety.—FANNY FIELD (in *American Prairie Farmer*).

#### PROPERTY IN HOMING PIGEONS.

A DECISION of much interest to Pigeon fanciers was given in the Birmingham County Court on the 9th inst., by Mr. J. Motteram, Q.C., in the case of Stanley v. Birch. The plaintiff claimed £5, the value of an Antwerp Pigeon shot by the defendant while flying over his grounds on its way home to Castle Bromwich from Aston, a place some five or six miles distant, where it had been tossed. His Honour in giving judgment entered into an elaborate review of the legal authorities bearing upon the case, and stated the questions for decision as follows—1, Whether the plaintiff could be said to have a property in the Pigeon, which was admittedly tame and reclaimed; and if so, then, 2, Whether by the act of taking the Pigeon away from its home for the purpose of training it, and there releasing it, the plaintiff lost his property in the bird, and thereby his right to bring the action to recover damages for the killing of it by the defendant—whether, in fact, the Pigeon, in consequence of the plaintiff's act, lost its character of a tame Pigeon and became *feræ naturæ*. His Honour, not without much hesitation and with some doubt, held that there could be property in a Pigeon, and that the mere taking the bird from its home and releasing it for the sole purpose of training it did not amount to an abandonment of the owner's property in the Pigeon. The plaintiff was therefore awarded a verdict for the £5 claimed and costs.

#### OUR LETTER BOX.

**Hops** (J. D., Wills).—The book to which you refer is probably a small work by Mr. Whitehead, entitled "Hops from the Set to the Skylights." It contains full particulars of the culture and preparation of Hops, and is illustrated. It is published by Effingham Wilson & Co., Royal Exchange, London.

#### REMARKS.

8th.—Bright, fine, and warm.  
9th.—Bright and fine, with fresh cold wind.  
10th.—Cool, overcast first part of the day, latter part bright and fine; moonlight evening.  
11th.—Cool, but fine and bright throughout.  
12th.—Fine sunny morning; overcast hazy afternoon; fine evening.  
13th.—Very fine and bright throughout; quite warm.  
14th.—Fair, but rather overcast and hazy.

Mean temperature nearly the same as in the previous week, and not very different from the average for the middle of May; but the range of temperature very great, that of the air being from 31.2° on the morning of the 11th to 74.1° on the afternoon of the 13th. The average daily range was 26.3°. The barometer was very high on the first four days, but fell rapidly on the 13th and 14th. No rain during the week.—G. J. SYMONS.

### THE PHYLLOXERA AND ITS ERADICATION.

HERE can be no question as to the destruction this insect is capable of effecting in vineries, and perhaps few subjects have received less attention from gardeners. This may be attributed to the fact that the evil wrought by the insect in this country has been comparatively limited. Like many gardeners, I confess I was entirely ignorant of the appearance of the Phylloxera and the conditions of the roots and foliage when attacked by it, until it was explained to me by a friend, who on inspecting the Vines under my charge found that they were infested with the pest. I have since wondered why some of those who have had Vines similarly affected should keep the matter such a profound secret. This appears to have been the case in many instances, as I have since learnt. I feel convinced that if those who have had experience with it had endeavoured to bring such a serious matter publicly before gardeners and amateurs, a sharp look-out would have been kept, especially when planting purchased Vines. Had I known in 1878 the appearance of the roots when attacked with the Phylloxera, I should not have had to contend with it in 1880.

My object in bringing forward this subject at the present time is to draw attention to the importance of carefully examining the roots of all Vines about to be planted, not only with the unassisted eye, but with a powerful lens. When attacked the extremities of the fibres present a knotted form that can be readily seen. This character being absent is not sufficient to indicate that the Vines are clean, as many insects may be present and have not had time to form this peculiar knotted appearance. I have found roots free from this, yet with numerous insects. In such cases the lens will prove of the greatest service in finding the insects, as they are very small and most difficult to see, especially on young growing fibres, as they much resemble them in colour. When, however, the insects become fully grown or are about to deposit their eggs, they are considerably larger than at any other time, and scarcely move. Just before they reach that stage they appear to seek a secluded place, if possible in the crevices of the old bark upon the roots. I could not find in one instance an insect with eggs at the extremities of the roots, or upon any of the young growing fibres. From my observations the females all appear to die after laying their eggs.

It has been stated that within the knots or galls upon the roots the young insects exist in different stages of growth. I am, however, inclined to doubt whether this is really the case,

as I have opened hundreds of the galls and neither found insects nor eggs, while upon the foliage every gall contained insects in a semi-dormant state or with eggs. The winged insects were very scarce, as I was only able to discover two, and these differed considerably, being probably in different stages of development. The insects were found in the greatest numbers where the soil was somewhat dry, especially under the pipes, but where it was rather wet few insects were found. In the vineries on another estate in the western counties, where the Vines had to be destroyed a short time afterwards, the roots had access to both inside and outside borders, and on the roots in the latter not an insect could be found, while on those in the former these destructive creatures were swarming. From the above facts I inferred that the Phylloxera did not like a wet soil, and on experimenting further found that when they are plunged into cold water life soon becomes extinct. Portions of roots were placed in a tank of water, and in several instances the insects entirely disappeared, in others when taken out after being in the water twelve hours and still adhering to the root were dead, and the vitality of the eggs remaining upon the root appeared to have been destroyed. I think that if affected pot Vines were plunged into water for some time they would be cleansed. This I do not wish to assert is certain to exterminate the Phylloxera, as I had no opportunity of testing this point further than with portions of roots. If this proved satisfactory with Vines in pots, it is questionable if a Vine border could be saturated to a sufficient extent to destroy the insect without the remedy proving injurious to the Vines.

Doubtless a thorough clear-out of the Vines and the contents of the border is the most satisfactory in the end, especially if there are other vineries in the same garden, but where there is only one vinery the Phylloxera can be stamped out without destroying or removing the soil from the border. The Vines and every particle of roots from amongst the soil and drainage should be searched for and burnt. There can be no doubt that the insects will die in time when they can obtain no food; but care must be exercised that every portion of root is removed, or the insect will continue to live as long as any nourishment can be obtained. The soil in the border should be turned over several times and a little hot lime mixed with it, and the pest will, I feel confident from my experience in the subject, soon disappear.

When the soil is removed from a large border and subjected to a burning process, much labour is entailed and some difficulty experienced in burning it, especially if it has been in the border for a long time, unless a quantity of wood can be obtained. The burning process I do not consider necessary if plenty of hot lime and some salt can be mixed with the soil. The border here was cleared and the soil carted to the farm for top-dressing. Some weeks after I examined the heap of soil and could not find a trace of the Phylloxera. The drainage was removed and placed in a heap in close proximity to a drain, the whole being covered with salt, and then thoroughly washed with a good force of water from a hose. This being done the heap was again covered with salt, and remained in that condition until early autumn. The brick and stonework of the house inside was first well washed with water and then with pure paraffin; at the end of a week it was again washed with salt and boiling water (for this latter excellent suggestion I was indebted to Mr. D. Thomson), the final washing being with

muriatic acid and water and the house well painted. The bottom of the border, which was bricked, was taken up and relaid, running hot lime between the crevices of the bricks. Some time afterwards, to be sure the house was thoroughly clean it was tested by placing a clean Vine in it, but no trace of the insect was again to be found. The drainage was again replaced and the salt process repeated, and the house employed during winter for forcing and growing French Beans.

The house here was attacked in the centre, and the Phylloxera appears to remain upon one Vine, or in one portion of the border until all the roots are devoured, then spread to contiguous Vines. Two or three Vines at each end of the house were clean, while in the centre of the house every root was covered with knots. Temporary Vines had been planted near the back of the border to fruit at the top of the house for a season or two. A space of 18 inches between the two borders was left, and the insects had not reached the temporary Vines.

I cannot think the Phylloxera establishes itself in vineries so mysteriously as many suppose without obtaining affected Vines in the first place, or wood for eyes from such Vines. The insects move so slowly that it appears impossible for them to travel from one district to another. The wind might carry them, but this appears rather impracticable, as the insect will only live a short time exposed to sun and air. If young fibres are exposed, which quickly shrivel and dry-up in the sun, the insects will not live so long as if a stronger root is exposed that remains fresh for a greater length of time. Apart from the roots they only live at the longest about thirty-eight hours. From various experiments I am thoroughly convinced that the Phylloxera will not attack the roots of any other plants.—WM. BARDNEY.

#### SPRING FLOWERS.

"Spring's delights are all reviving,  
Verdant leaflets clothe each spray."

SPRING in its almost full maturity is upon us, daily growing more beautiful, and swiftly merging into early summer. From the opening of the first Snowdrops and Crocuses we have at first daily, and now almost hourly, additions of floral beauty till "spring's delights" culminate in the regal richness of the Rhododendron and the softer tints of Kalmias and Azaleas, the first flowers of which are just open, and from which we shall turn with lingering regret to greet the first Roses of summer in "leafy June."

That old friend of my boyhood, *Omphalodes verna*, has been very beautiful with its abundant clusters of deep blue flowers. Its great beauty and easy culture have often been pointed out in the Journal, and I am glad at length to see high praise awarded it and a discussion of its merits and culture in a contemporary. Runners taken off and planted now soon make large clumps—so large that some care is required to keep it within bounds. It is planted here with Solomon's Seal, *Pæonies*, and other perennials, among which it rambles unchecked, spreading almost as fast as *Lily of the Valley*.

*Myosotis sylvatica*, *Silene*, and other annuals are now in full beauty. The culture of these useful and easily managed plants has long ago been explained, but failures are still by no means uncommon, and they are generally found to arise from a mistaken idea that seeds of all sorts should be sown at the same time. It may, therefore, be useful to state once more that *Myosotis* for spring beds should be sown the third week in June; *Eschscholtzia* a fortnight later; *Silene* the third week in July; *Saponaria calabrica*, *Alyssum maritimum*, and *Iberis* the third week in August; *Nemophila*, *Collinsia*, *Limnanthes Douglassii*, and *Lasthenia californica* a week later. Sow in drills in a garden border of rich light soil, prick out into nursery beds as soon as the plants are large enough, and transplant to the beds immediately after the summer plants are cleared off. Give especial care to plant *Nemophilas* and *Saponarias* in light porous soil well elevated above the common level and drained.

*Lily of the Valley* is now in full beauty. Every garden should have a few patches of it. My best bed is on a low bank shaded by trees and thinly planted with shrubs, among which the pretty little *Lily* has spread far and wide with surprising rapidity. It loves good soil, and is certainly worthy of it. Break up the soil and insert the plants in small clusters a foot apart; keep down weeds for two or three years till the plants meet, but do not dig among them, and the bed once established will last for a lifetime.

The dry weather caused *Daphne pontica* to shed its flowers sooner than usual this year. It thrives and soon grows into large specimens in a light sandy soil. *Daphne cneorum* is now laden with its pretty pink flowers, which "scent the air with sweet perfume." To have it in perfection it must be planted in sweet wholesome fibrous peat—not wet black sour peat from a sodden bog. The *Andromedas*, too, are opening their pretty white Heath-like flowers. The robust *A. formosum* has been in bloom for some time, but I much prefer my favourite *A. Catesbæi*, which is not yet in full beauty.

Let us turn from the shrubs to the rockery, and the eye is at once arrested by the long trailing growth of *Lithospermum prostratum*, studded thickly with deep blue flowers. The plants are large, for they have been left undisturbed for five or six years. Some are growing singly, but two are intermingled with a variegated *Honeysuckle*, and the beauty of the flowers is much enhanced by its delicate yellow foliage. Upon the low rock beds there are several plants of *Azalea amœna*, that are just now masses of deep pink blossom clustering so thickly upon the branches that the foliage is quite lost to view. There are several lovely pink cushions of *Phlox frondosa*, and equally attractive white masses of *Phlox Nelsoni*.

*Saxifraga pyramidalis* is throwing up its bold flower spikes that will ere long become lovely tapering cones of white flowers a foot or two in height. This fine *Saxifraga* gives numerous offsets, which should be taken off and planted singly in order to secure fine spikes of bloom. Most of the minor *Saxifrages* contribute their little cluster of white flowers, and *S. muscoides rubra* is a red sparkling gem. A charming soft downy cushion of *Thymus lanuginosus* is studded with pretty little pink flowers. It is extremely dwarf, hardly rising an inch above the surface of the soil in which it is planted, but it has spread its velvety growth upwards over two large masses of rock, clothing them so beautifully that is now one of the most attractive of the rock plants. This plant and the aromatic *Thymus corsicus* were given me some five years ago by a friend who has since gone to his rest, and they have spread with equal rapidity, but the former is decidedly the more ornamental.

I have not devoted the rock beds altogether to alpine plants. There are plenty of them in little nooks and trailing over the rocks, but they are broken up into groups and colonies by plants of bolder aspect, such as *Erica carnea*, which has been very beautiful but has now done blooming, *Azalea amœna*, *Rhododendron ferrugineum*, *Erica Foxii*, so remarkable for its compact globular outline and tiny flowers, *Kalmia nana*, *K. glauca*, *Andromeda polifolia*, and *A. polifolia angustifolia*, both having pale pink flowers and forming pretty dwarf bushes.

As we go from the rocks past the pond containing the hardy aquatics we see *Aponogeton distachyon* in full bloom; it is often called the Water Hawthorn from the sweet scent of its singular pure white flowers. Along the side of the pond there are other white flowers springing upwards from stout trailing stems into spikes of great beauty. The unopened flower buds are charmingly tinged with pink, but the expanded flowers are quite white, and are most curious from the fact of the entire inner surface being thickly set with delicate filaments. This is the Bog Bean, *Menyanthes trifoliata*. It is one of our loveliest native plants. I found it growing in a bog on Ashdown Forest, among which also grew thousands of *Drosera rotundiflora*, *Asphodel*, and Bog Cotton. In its wild state the Bog Bean is not very attractive, but under cultivation its foliage and blossom become very ornamental.

There are many other spring flowers worthy of notice, for all are beautiful. The Mountain Ash is just opening its sweet flowers; the grand old Lilacs are laden with huge clusters; the Laburnums will soon wave their golden arms, rich with a wealth of floral beauty that imparts a peculiar and most attractive aspect to the garden. Soon will the Gueldres Roses give us their huge white snowballs again, and the Weigelas put on their vernal display of pink and white blossom that in the distance is not unlike Apple blossom. Apple blossom! is it not glorious this spring? The pyramids are very beautiful, but they are altogether eclipsed by the huge old standards at the farm, unpruned and wild-like, but so picturesque!—EDWARD LUCKHURST.

LOW *versus* HIGH NIGHT TEMPERATURES FOR MUSCAT GRAPES.—At page 383 a correspondent remarks that Mr. Simpson has not had justice done him in the matter of low night temperatures for Vines, which he has for a long time advocated. In going through the houses lately at Wortley when the Muscats were setting I noticed on a slate (one of which is hung in every house) the following figures for the men's guidance—Day temperature, with sun, 80° to 90°; dull days 60° to 65°; night 50°. In a Black Hamburg house, where the bunches were well out

but not in flower, the temperatures were—maximum, 75° to 80°; minimum, 45°. Mr. Simpson told me he gradually raised the temperature up to that period. The Muscat bunches that were set were crowded with berries, and this in a temperature 25° below what was advocated at one period. The saving of fuel alone, I was informed, was very considerable. I also noticed the houses were not so dry as one usually sees them when the Vines are in flower, as they are regularly syringed on bright afternoons during the flowering period, and the Vines were all in the best possible health.—G. S., *Sandbeck Park*.

### ASPARAGUS.

I BELONG to what the trim and starched modern professors of gardening of the present day might describe as the patriarchal school of cultivators, and my views on Asparagus may not possibly be accepted by all readers. Such a hard-headed veteran as myself, who does not believe that the great Potato exhibitions have been of substantial benefit, may fairly be regarded as "fossilised" from the point of view of the advanced order of beings who are ever thirsting for something new, and cannot rest if not engaged in revolutionising something or other. Yet, antiquated as my notions may possibly be deemed, I have yet a strong inclination to see and to grow garden produce, both flowers and vegetables, of the best quality. Flowers I conceive are grown to give pleasure to the eye and mind, vegetables to afford gratification to the palate and to afford sustenance to the body; therefore, however large and "noble" a Potato may be in appearance, if it is not of superior quality when cooked, I hold that ground and labour have been wasted in growing it; and if a dish of such tubers were to be awarded fifty prizes by the fanciers, the value of the variety would not be increased in my estimation. It would fail in the one great object for which Potatoes are required, and its charm is then gone for me.

Asparagus, like Potatoes, is grown to be eaten, and in my experience excellence of quality should be the chief object of culture, because it is certainly the point most valued by all the consumers (and they have been both numerous and critical) that it has been my lot to provide for. If we produce heads of Asparagus weighing half a pound, and yet only about an ounce and a half at the tips can be eaten, we are, I respectfully submit, like the man in the boat, progressing backwards, for we are extracting a maximum amount of the soil's most valuable constituents in the production of a minimum quantity of food, the bulk, or nearly seven-eighths of the whole, finding refuge in the swill tub. And I am not sure that it is not wasted even there, making a double waste, for I have seen hungry pigs refuse to eat the white tough ends that have been cut from the heads.

Now, as a gardener I am quite unwilling to expend my labour in growing produce of the kind referred to; and if I were an employer I should most decidedly object to any fancy process of culture by which such results are achieved as being economically unsound. Large heads I do not object to, provided they are not too large for an average-sized mouth, and I am not sure that I object to them even then; but my employer does, for he has told me so, and warned me not to overstep the mark in that important respect; but the greatest possible portion of those large heads must be such as human beings can eat, and not such as pigs refuse, for this is not what I call good gardening.

Asparagus, so far as I understand it, and judging also by the estimate of quality as decided by connoisseurs, is never so good as when it is grown so quickly by the aid of good soil and warm genial weather that the heads can be snapped off like glass near the surface of the soil. The produce is then buttery, juicy, and delicious, while it is also at the same time of the greatest possible medicinal value, inasmuch as the peculiar crystalline alkaloid, asparagine, is then developed—at least so an eminent scientific man has informed me, who has given much attention to the subject, prompted, I believe, to a great extent by the gout.

I have not been impelled by the same painful stimulant to refer to the subject in hand now, but was led to think over the matter after reading in the last week's Journal a note about an Asparagus competition that is to be held next month. I have not one word to say against this. If it will encourage the production of a greater amount of Asparagus of superior quality from a given piece of ground than before, it will be of great general advantage; but whether this end will be accomplished will depend, in my view of the case, to a great extent on the judges, and the principles by which they are guided in giving their decisions. The matter, it seems to me, is of too great importance to be dealt with on mere "fancy" grounds. We are told that "the prizes will be given to the largest Asparagus, provided it be in all other respects unobjectionable." The importance of this condition depends

wholly on the interpretation of its qualification. What is to be understood by the term "unobjectionable?" Everything depends on that in arriving at a sound rational common-sense judgment.

I can grow Asparagus far better than write about it, and am more at home in digging a piece of ground than in attempting an exercise in logic; but I cannot help thinking that as Asparagus is not grown as a flower to gratify the eye, but to be eaten, that the bundle of heads which contains the greatest weight of stalks that cannot be eaten by man or pigs is the most objectionable, and the bundle containing the least amount of waste is the most meritorious. Medium-sized green heads and stalks, what may be called the best English-grown produce, contain decidedly less waste than the huge white blanched stalks with red tips grown on the French system; and yet the former that contains the greatest proportionate amount, or even the greatest actual amount of eatable produce would under some adjudicators have slight chance of winning a prize against the "largest" heads grown on the blanching system and which contain a much less weight that can be eaten. Or to put it another way, when the resources of the ground have been applied in the fullest manner for the production of food, the cultivator gets no prize, while if the soil has been exhausted or manure employed in growing a maximum amount of waste the cultivator is honoured. The Judges at Tunbridge Wells have a difficult task to perform, and unless they take a practical, not a mere fanciful, view of the whole subject they will run the risk of giving prizes to what really amounts to soil-exhaustion, while those cultivators who turn its resources to the best account will be left out in the cold. It is not the farmer who grows the most straw and the least grain that is doing the best for himself and the land, for waste and weeds are synonymous, and both, or either, lead to bankruptcy; and what cannot be utilised of garden produce is as much waste in the garden as weeds are on the farm.

Sixty heads, each 6 inches in length and as thick as a man's thumb, of well-grown Asparagus, every particle green, and two-thirds of it tender, represent better and more economical cultivation than the same number of blanched and Frenchified heads 8 inches long and as big as the paws of a prize tom cat, if three-fourths of each head, as is often the case, is waste. But it may be asked, Why not grow the green heads and stalks as large as the white? I know there are some people who call themselves horticulturists who betray their ignorance by making this proposition, and have led gentlemen who do not profess to study these matters to think it is practicable, to the discomfort of their gardeners. It is not practicable nor possible. No gardener, no Frenchman, can grow stalks of Asparagus 9 inches long, and green and crisp throughout, so large and heavy as the white tough stalks of the same length. A law of Nature is against him. So long as the growths are covered with soil they increase in thickness as they advance in growth, but the moment the stems are above ground they commence diminishing in thickness, and the cultivator can no more prevent this than he can prevent the trunk of a Larch tree tapering to the top. This was stated some time ago by a writer in the Journal, and it is perfectly true. It is right that gentlemen should know it, then they can decide whether they will sacrifice quality for size or not, and instruct their gardeners accordingly. I have been instructed on this matter, and the circumstance may as well be stated.

Some years ago my employer brought me some wonderful Asparagus from France. He did not say he desired me to grow some of the same kind, but I fancied it was my duty to try the blanching system. In due time I was able to send some huge white heads in the London hamper with the usual supply of the ordinary green produce; and I confess I was not surprised to receive the following order:—"Don't send any more of that big French Asparagus, as neither my family nor friends like it so well as the other, and there appears to be so much waste about it."

Let those who like the large blanched produce have it by all means, but let them count the cost of its production by weighing the waste, and what it represents of the soil's resources. I am amongst a large number who are like the waiter in *Punch*, who after remarking "how universal is the love of sparrow-grass," sententiously observed, "I don't enjoy it so much myself now they're grown such a size and such a colour. I like my grass green, as seems more natural."—A COUNTRY GARDENER.

A NEW PRODUCT FROM BIRCH BARK.—A French inventor has recently patented a method of improving indiarubber and gutta percha by the addition of a distillate of Birch bark. By distilling the outer layers of the bark he obtains a dense black gummy matter, which possesses the properties of ordinary gutta percha with the additional quality of resisting both the action of air and the strongest corrosive acids. He claims also that by

adding a small proportion of the Birch bark gum to gutta percha or to indiarubber (one twentieth part will suffice), the durability of the rubber or the gutta percha will be greatly increased, the new mixture not being acted upon by the air or by acids.—(*The British Mail*.)

### READING HORTICULTURAL SOCIETY.

MAY 19TH.

IN some respects the spring Show held at Reading on Thursday last has scarcely been surpassed by previous exhibitions of the Society at the same period of the year, for though the number of exhibits has been greater, the general freshness and health of the plants has not been excelled, and in several of the leading classes admirable examples of cultural skill were noticeable. Flowering plants were in point of numbers well balanced by those grown chiefly for their foliage, and the tasteful arrangement produced an effect that was bright, but agreeably toned by the Palms, Ferns, and similar plants in the last-mentioned classes. As usual the picturesque Abbey Rhns was selected for the Show, and the day proving fine induced a very large company to assemble.

**STOVE AND GREENHOUSE PLANTS.**—Several very satisfactory collections were contributed in the classes devoted to these plants, but in the principal class there was no competition though the prizes were liberal. The only exhibitor of twelve specimens was Mr. Lees, gardener to Mrs. Marsland, The Wilderness, who was deservedly awarded the first prize for healthy well-flowered plants. The most noteworthy were the following—*Mussaenda frondosa*, about 4 feet in diameter, not formally trained, but extremely vigorous, and bearing a very large number of its bright yellow tubular flowers accompanied by large pure white bracts. This well-known and beautiful stove shrub is rarely seen in better condition than that staged by Mr. Lees; in fact it is by no means a common exhibition plant. *Franciscea calycina* major was also well represented with flowers fully 4 inches in diameter, and of the rich purple colour that characterises the variety. *Clerodendron Balfourianum* was healthy and well flowered; *Erica Cavendishiana*, notable for the deep colour of the flowers; *Rhynchospermum jasminoides*, vigorous, but with few flowers; *Vinca alba*, *Azalea Bernhard Andreas*, *Erica depressa* major, and several others completed this satisfactory collection. There were two competitors in the class for six specimen stove and greenhouse plants; Mr. Hope, gardener to the Hon. R. Boyle, Purley, securing the chief prize with *Plumbago capensis* profusely flowered; *Lantana splendens*, 5 feet high, trained on a balloon-shaped trellis and remarkably healthy. *Tecoma jasminoides* was rather rough, but *Bougainvillea glabra* and *Tabernaemontana coronaria flore-pleno* were creditably shown. Mr. Bennett, gardener to M. Lonergan, Esq., Cressingham, was adjudged the second place with neat specimens, among which a good specimen of *Azalea Fjelder's White* was notable. In the amateurs' class for four specimens Mr. Mortimer, gardener to Major Storer, Purley Park, was the only exhibitor, securing the second prize for moderately good examples of *Plumbago capensis*, *Rhynchospermum jasminoides*, and *Bougainvillea glabra*. For a single specimen Mr. Ashby, gardener to W. Fanning, Esq., obtained the chief award with *Rhododendron Michael Waterer* bearing numerous large trusses of flowers. Mr. Armitage, gardener to N. Clarke, Esq., followed with an evenly trained *Tetradlea verticillata*; and Mr. Baskett, gardener to W. J. Palmer, Esq., took the third position with *Tabernaemontana coronaria* 5 feet in diameter and very healthy, though the flowers were not quite sufficiently advanced.

**Azaleas.**—The principal collection of Azaleas formed a bank at the lower end of the tent, the enormous specimens from Mr. Bennett—for which the chief prize in the open class for nine was awarded—particularly attracting attention. These were of pyramidal form, some exceeding 6 feet in height, well clothed with foliage and flowers. The best were *Etoile de Gand*, *Stella*, and *Flag of Truce*, the last-named being in especially satisfactory condition. Mr. Lees secured the second position with a less even collection, but including some fine specimens; *Souvenir du Prince Albert* was flowering profusely, Vivid brightly coloured, and *Admiral Napier* a very large plant—even larger than most of Mr. Bennett's, and also satisfactory in other respects. Mr. Armitage was third with much smaller but neat plants. Mr. Lockie, gardener to Lord O. Fitzgerald, Windsor, and Mr. Mortimer were the prizetakers in the amateurs' class for four Azaleas in the order named, the former showing neat well-flowered specimens of medium size, *Duchesse Adelaide de Nassau*, *Blushing Bride*, and *Roi d'Hollande* being the best. The others were not trained, but fairly good. In the class for six Azaleas in 8-inch pots three neat collections were staged, Mr. Lees taking the chief position with even well-flowered plants, including *Roi d'Hollande*, *Hermine*, and *A. Van Geert* in first-rate form. Mr. Lockie was a close second with rather smaller specimens, Mr. Armitage securing the third prize with a less even contribution.

**Pelargoniums.**—These were not so numerous as they have been at some previous shows, but moderately good plants for the season were staged by several exhibitors. For nine show varieties in 8-inch pots Mr. Ashby gained the first prize with well-flowered healthy plants,

the best being *Duchess of Edinburgh*, *Ruth*, *Triomphe de St. Mande*, *Alchemist*, and *Prince of Pelargoniums*, all useful and well-known varieties. Mr. Mortimer followed with fairly good plants, among which *Empress Eugenie*, *Red Gauntlet*, and *Lady of the Lake* were particularly noteworthy for the size and substance of their flowers. Mr. Burgess, gardener to Colonel Clayton, Maidenhead, was accorded the third position for neat examples of *Maid of Honour* and *Spotted Gem*, and others nearly as good. This exhibitor also sent the only collection of six Fancy varieties, for which the chief prize was deservedly awarded. *Fanny Gair*, *The Shah*, *East Lynn*, and *Pilgrimage* were finely represented, all the plants being even and the flowers brightly coloured.

**Roses** were neither numerous nor generally in very satisfactory condition, only one really first-rate collection of plants being staged. In the open class for six specimens, distinct varieties, Mr. Lees was awarded the principal prize; but though his plants were healthy they were rather rough, and except on *John Hopper* the blooms were not of such substance and form as might be desirable. Mr. Tranter, Upper Assenden, was second with plants of medium size and well-developed foliage. *Dupuy-Jamain* had some good blooms, and several other varieties were fairly represented. In the amateurs' class for four Roses Mr. Lockie was the most successful exhibitor, and very well he merited the prize awarded him, for the plants were by far the best in the Show. They were even, vigorous, with fine foliage, and several bore really handsome blooms; *Madame Hippolyte Jamain*, *Oxonian*, and *Madame Thérèse Levet* being the varieties best represented. Mr. Baskett followed, his plants being taller and not so compact. *La France* had several flowers of good substance.

**Gloxinias and Calceolarias.**—The chief prize for six *Gloxinias* was secured by Mr. Baskett, who exhibited large handsome specimens in 8-inch pots. The foliage was remarkably fine, the flowers large, of good form, and bright colours. The plants, it was stated, had been raised from Messrs. Sutton & Sons' strain of seed. Mr. Durman, gardener to W. Workman, Esq., was second, also staging plants bearing good flowers. Mr. Mortimer followed with fair examples. The best six *Calceolarias* were contributed by the last-named exhibitor, who well deserved the prize accorded him. The plants were compact, even, with abundant well-formed brightly coloured flowers, the only defect being the slightly yellowish foliage; with that exception the plants were very satisfactory. Messrs. Lockie and Bennett secured the remaining prizes in the order named with moderately good plants. *Fuchsias* and *Ericas* were not numerous nor in excellent condition.

**Orchids.**—Very liberal provision is not usually made for Orchids at Reading, nor is the display extensive, yet in the five or six small collections staged at the last Show there were several pretty little specimens of considerable merit. For three specimens Mr. Pound, gardener to G. May, Esq., Caversham Warren, was first with a robust example of *Dendrobium thyrsiflorum* in a small basket, and bearing three fine trusses of flowers; a handsome variety of *Dendrobium Falcoueri* with large richly coloured flowers, this was also in a basket and very vigorous—there could not have been much less than a hundred flowers and unexpanded buds; *Vanda suavis* was represented by a small plant of a good variety bearing four trusses. The second position was secured by Mr. Baskett with *Oncidium sphacelatum*, *Odontoglossum citrosum*, and *Dendrobium thyrsiflorum*, all neat and healthy. An extra prize was accorded to Mr. Atkins, gardener to Col. Lloyd Lindsay, M.P., Lockinge Park, for *Cattleya Mossiae*; *Dendrobium nobile*, fine variety, well flowered; and *Cypripedium barbatum*. The best single specimen was *Dendrobium Falcoueri* from Mr. Pound, a fine example of a beautiful Orchid. It was growing on a Tree Fern stem about 2½ feet high, and had abundance of richly coloured flowers. Mr. Hope took the second prize for a healthy *Dendrobium thyrsiflorum* with over a dozen trusses of large flowers.

**FINE-FOLIAGE PLANTS.**—The chief class was that for nine specimens, and two satisfactory collections were staged. Mr. Mortimer was a good first with large well-grown specimens, of which *Cissus discolor*, *Croton Weismanni*, well coloured and healthy, *Alocasia macrorrhiza* variegata, variegatum, clearly and distinctly marked, *Latania borbonica*, *Alocasia metallica*, and *Yucca aloifolia* variegata were the most notable. Mr. Bezan, gardener to H. T. Simonds, Esq., Caversham, was second with healthy examples of *Maranta Makoyana*, *Croton variegatus*, and *Cissus discolor*. In the amateur class for four specimens two collections were also staged—namely, by Messrs. Lees and Hope, who were awarded the first and second prizes in that order. The former had a vigorous *Pandanus Veitchi*, a large well-furnished *Cycas revoluta*, *Croton Weismanni* of good colour, and *Latania borbonica*, very large. The most noticeable plants among Mr. Hope's were *Cissus discolor* and *Pandanus Veitchi*, both admirably grown.

**Ferns.**—Mr. Mortimer was again to the front with nine Ferns, staging the large healthy specimens which have often obtained similar honours, and been approvingly noted in these pages. *Adiantum cardiochlaena*, *A. concinnum latum*, *A. gracillimum*, and *Gymnogramma chrysophylla* were in unusually fine condition with abundance of healthy fronds. These Ferns constituted an imposing group arranged on one of the mounds sloping to the centre of the tent. Those from Mr. Bezan, who was placed second, were much smaller but healthy, the best in his collection being *Adiantum trapeziforme* and *A. punctum*. Mr. Lees was the chief exhibitor of four

specimens, including a very fine *Platyserium alcicornis*, such as is seldom seen at exhibitions. Mr. Hope was a close second with clean and even plants, *Adiantum cuneatum* being particularly fine. For a single specimen Mr. Bezan secured the first prize with a large *Alsophila australis*, Mr. Mortimer following very closely with a similarly large and remarkably healthy *Davallia Mooreana*, 5 or 6 feet in diameter and bearing some uncommonly large fresh fronds. These two plants were nearly equally meritorious. The only collection of *Selaginellas* was that from Mr. Mortimer, who exhibited his customary neat conical specimens for which the first prize was deservedly awarded.

**Groups.**—These formed an important feature in the Show, and were generally bright. For a group to occupy a space 10 feet by 12 there were five competitors, the most successful being Mr. Baskett, who had a tasteful arrangement of Roses, *Dielytras*, Azaleas, *Spiraeas*, and *Gloxinias*, with sufficient fine-foliage plants to tone the brightness imparted by the others. Mr. Bennett, who was second, had a group containing rather more colour, Zonal *Pelargoniums* and *Cinerarias* rather too strongly predominating. Mr. Burbidge, gardener to B. Simonds, Esq., was third with a neat collection, chiefly noteworthy for the fine *Richardias* and the edging of *Adiantum gracillimum*, *Isolepis gracilis*, and *Selaginellas*. Extra prizes were obtained by Mr. Powell, gardener to F. J. Blandy, Esq., and Mr. Mayne, gardener to Miss Moon, both staging attractive groups, but the first-named was rather too formal, and the last too thin. Mr. Pound was the only exhibitor of a smaller group (6 feet by 4), which included several fine *Dendrobes*, especially *D. Falconeri*. Two groups of *Rhododendrons* were exhibited by Mr. Ashby, gardener to W. Fanning, Esq., Whitechurch, and Mr. Bennett, the former including plants with fine trusses of blooms representing some of the best varieties. Groups of hardy plants were also shown, but not of any remarkable merit. Messrs. Lees and Bennett were the chief prizetakers.

**Cut Flowers.**—Mr. Bennett contributed the finest collection of twelve bunches, and easily won the first prize; some of the most noteworthy in his stand being *Brugmansia Knightii*, *Dendrobium Pierardi*, *Begonia nitida alba*, and *Gloxinias*. Mr. Atkins was second, staging very neat blooms; the *Eucharis*, *Tacsonia exoniensis*, and *Rhododendron Gibsoni* being unusually fine. In the amateurs' class Messrs. Mortimer, Hope, and Burgess were the chief exhibitors, the first-named having handsome blooms of *Pancreatium fragrans* and *Dendrobium Devonianum*. Cut Roses were represented by three collections from Messrs. Tranter, Lees, and Lockie, who were awarded the prizes in that order. The premier blooms from Mr. Tranter included some fine examples of *Maréchal Niel*, *Madame Victor Verdier*, *Emilie d'Hausburg*, *Souvenir d'un Ami*, and *Richard Wallace*, all fresh, of good substance and form. The other exhibitors also contributed fair blooms—*Madame Bravy*, *Jean Pernet*, and *La France*. Mrs. Owen Knox of Caversham sent a handsome collection of twelve Fancy Pansy blooms, very even and brightly coloured. Bouquets, buttonholes, and ornamental stands of flowers were numerous as usual from various lady residents of the town. Mr. Phippen carried off several prizes; and Mr. Millen, gardener to the Marquis of Donegal, Hampton Park, was also successful.

**FRUIT AND VEGETABLES.**—Strawberries were not abundant, but several of the collections included some remarkably fine fruits. Mr. Mortimer was adjudged the first prize for a dish of thirty-six fruits, the variety being *President* in extremely fine condition, very even in size and of excellent colour. Another box of the same variety from Mr. Mortimer, containing fifty-four fruits nearly as good as those in the class, was highly commended by the Judges. Mr. Hope followed with the same variety. Peaches were shown by Mr. Fowle, gardener to Sir H. St. John Mildmay, Bart., Dogmersfield, and Mr. Ashby, those from the former being well ripened and of good size. Grapes were poor, the best being a neat bunch of Black Hamburg from Mr. Ashby. Mr. Atkins obtained a certificate of merit for fruits of *Melon Hero* of Lockinge, finely netted, neat in form, and excellently ripened. In the Society's class for the best brace of Cucumbers there was close competition. Mr. Lockie was placed first with *Masterpiece*, even, handsome, and bearing fine bloom. Mr. Atkins was second with *Improved Telegraph*, not quite so even, but very good examples. There was also very keen competition for Messrs. Suttons' prizes, the premier award being secured by Mr. Howe with a brace of handsome Cucumbers, the produce of a plant raised from seeds obtained from a cross between *Freeman's Yard Long* and *Telegraph*. They were long, even, and bearing good bloom. A certificate of merit was awarded for the variety, which was named *Challenger*, and is described as very prolific. Mr. Lockie was second with fine examples of *Model*; and Mr. Ross, gardener to C. Eyre, Esq., Welford Park, was third with *Tender* and *True*.

Collections of vegetables were shown by Mr. Lockie, who was first with good Asparagus, *Model* Potatoes, *Enfield Market* Cabbage, &c. Mr. Read, gardener to F. Wilder, Esq., Purley Hill, was a good second. In the class for Peas the first prize was awarded to Mr. Burbidge for Suttons' new variety *American Wonder*; and in Potatoes Mr. Lockie was first with *Woodstock Kidney*, very fine. Other vegetables, such as Cauliflowers, were also fairly represented.

The chief miscellaneous group was from Mr. C. Turner of Slough, and comprised a number of handsome young Azaleas and *Pelargoniums*. Certificates of merit were awarded for the beautiful double white *Azalea indica Madeleine*, previously noted in this Journal, and for the tricolor *Pelargonium* Mr. Henry Cox with neatly formed richly coloured foliage. Mr. Tranter contributed a box of un-

commonly fine *Maréchal Niel* Roses, for which an extra prize was deservedly awarded. They were of good size, excellent form, and great substance, being very creditable to the grower.

#### BOUVARDIA ALFRED NEUNER.

THE double *Bouvardia* represented in the annexed woodcut is of American origin, and has been described by Mr. Meehan as possessing considerable beauty. The flowers are said to be pure white and completely double, as shown in fig. 91, which has been forwarded to us by Messrs. J. Carter & Co. of High Holborn, who state that they have been appointed the sole agents in England of the American firm now sending it out. Should the plant prove equal to the representation, it will undoubtedly be valuable for

Fig. 91.—*Bouvardia Alfred Neuner*.

decorative purposes and affording a supply of flowers that would be well suited for bouquets. We may add that it is said to be a sport from *Bouvardia Davidsonii*, and was certificated by the New York Horticultural Society early in the present year.

#### ROYAL WESTERN HORTICULTURAL SOCIETY.

MAY 17TH AND 18TH.

THIS Society last year discontinued their spring Show for want of sufficient means, but it is now reconstituted, and by the energy and tact of the new executive a display was collected in the spacious building, St. Andrew's Skating Rink, Plymouth, worthy of the town and neighbourhood, and the best this old-established Society has ever held.

Many special prizes were offered, and among them were the following:—The President's prize, E. C. Baring, Esq., of ten guineas for dinner table, 4 feet 6 inches by 10 feet, completely and fully laid for ten persons; the Mayor's prizes of three guineas for table decoration, a vase or ornamental stand; the borough member's prize of five guineas given by P. S. Maccliver, Esq., M.P., for twelve stove and greenhouse plants, six in bloom; the borough member's prize of five guineas given by E. Clarke, Esq., M.P., for the best collection of Azaleas sent out since 1874; the Chairman's prize of ten guineas given by W. Derry, Esq., for twelve Roses in pots; and a silver cup, value three guineas, given by C. R. Barden, Esq., for the best specimen plant in bloom. The schedule contained fifty classes, the majority of which being well represented, and completely crowding a large hall 166 feet long by 109 feet broad.

Messrs. Lucombe, Pince & Co. of Exeter contributed a group of miscellaneous and decorative plants which is acknowledged to be the best that was ever seen at Plymouth before; amongst others were some grand examples of *Bougainvillea glabra*, *Stephanotis floribunda*, *Allamanda grandiflora*, *Anthurium Schertzerianum*, *Crotons undulatus* and *interruptus*, a large collection of Azaleas including the best varieties; Ferns, Palms, and decorative plants, including a couple

of boxes of the beautiful Tea Rose Niphetos. Stove and greenhouse plants were largely contributed by the Earl of Mount Edgcumbe; Sir J. Amory Heathcote, Bart., M.P., Tiverton; H. B. Mildmay, Esq., Flete; E. C. Baring, Esq., Membland; E. Allen, Esq., Ivy Bridge; R. Parson, Esq., St. Austell; and W. Derry, Esq., Plymouth. The collection from Sir J. Amory Heathcote were admirable examples of cultural skill, and worthily deserved the first prize and extra certificate of culture awarded to them. The same contributor staged some most excellent specimen Azaleas, in each case gaining first honours. Mr. J. R. Challice, nurseryman, Plympton, gained the borough member's prize for the best collection of Azaleas sent out since 1874. Pelargoniums, Calceolarias, Mignonette, Petunias, Begonias, and Gloxinias were freely contributed, and the chief prize-takers in these classes were Admiral Curme, Lord Francis Cecil, Messrs. Mildmay, Allen, Hamilton Whiteford, J. Watts, Amos Groombridge, and Derry. Roses, of which there were two classes—one for twenty-four varieties not to exceed three of each variety, and the other for twelve varieties and the same conditions—were contributed by Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston; Mr. Smith, St. Austell; and Messrs. Curtis, Sandford & Co., Devon Rosery, Torquay. In the class for twenty-four Mr. Moorman was awarded the first place, and Mr. Smith the second; and in the smaller class Messrs. Curtis, Sandford & Co., first, and Mr. Moorman the second prize.

Vegetables were abundantly exhibited considering the earliness of the season, and were especially good; Grapes, Strawberries, and Gooseberries were represented in the fruit classes, while Cucumbers formed an extensive display.

The weather on both days was bad, the only two unsettled days during the present dry spring, nevertheless there was a fair attendance of visitors. The arrangements were admirable, and the long list of exhibitors as well as visitors are indebted to Messrs. Walling and Bond, the Hon. Secretaries, for their particularly courteous and attentive demeanour to all.

### THE MARÉCHAL NIEL ROSE.

FEW places have made more rapid progress in Rose cultivation than Reigate, and few places, I venture to say, have more really practical admirers of its favourite flower. This was manifested at the last National Show by the large number of prizes taken by members of our Association.

Amongst these members, as amongst all Rose-growers, there are still various opinions, however; not as to the grandeur of this Rose, the Maréchal, when in perfection, but as to the uncertainty of producing it in that state. "It is so very precarious," say some. "It is useless to attempt to grow it without protection," say others. Then, again, "It will not bear coddling." Under these circumstances it struck me that to state how it is grown in perfection may be useful to its many admirers, and do something to convert those "who have their doubts about it." The other day I saw it in "cold house" without any special pretensions or favour, except a southern aspect, grown by one of our members, Mr. Badger, in such beauty and profusion which would at once excite admiration in any lover of the Rose. On some four or five plants there must have been not less than eight hundred blossoms in every possible stage of beauty. These plants had had no artificial heat; of course good soil, as much fresh air as possible, and the usual steps had been taken to keep them clean. The result was one which any Rose-grower or lover would be pleased to obtain, and I hope these few lines may induce at least some to enjoy a like success in the cultivation of this beautiful Rose.—JOHN PAYNE, *Treasurer, Reigate Rose Association.*

### FLORAL EXHIBITION AT THE ALEXANDRA PALACE.

THE first of a series of special exhibitions was held on Friday and Saturday last, being on this occasion devoted to table and floral decorations and Roses in pots. The Clematises from Messrs. Jackman & Son of Woking also remained on view, and with groups provided from the Palace gardens a pleasing display was produced under the careful superintendence of Mr. J. Forsyth Johnson. The lessees offered very liberal prizes in twelve classes, in some of which a much keener competition might have been expected considering the value of the prizes. In many of the arrangements of the tables also there was considerable room for improvement, several exhibitors employing too much material, overloading the tables and producing a heavy appearance, others having too many brightly coloured flowers and insufficient foliage to tone the rather glaring effect produced. However, these were the exceptions, for the majority of the winning exhibits were fairly tasteful and satisfactory. Originality in this as in many other artistic works is not too common, and the great attractions of decoration, simplicity of design combined with effectiveness, are frequently lost sight of by those who employ their time and attention in such work.

The most imposing feature of the Show were the groups of Roses in pots from Messrs. G. Paul & Son, Cheshunt, the only entries in the

two classes devoted to Roses, and which well merited the premier prizes awarded for them. The large specimens were in admirable condition, fresh, healthy, and vigorous, the foliage fine, the blooms numerous and generally of good size and substance. Charles Lawson was particularly fine, the colour being very bright and the flowers large; Dr. André, Victor Verdier, and Madame Victor Verdier were similarly attractive. On each side of the large specimens the small plants—i.e., those in 10-inch pots, were arranged. These were also in creditable form, Duchesse de Vallombrosa, Perfection de Montplaisir, Madame Thérèse Levet, and Madame Lacharme being the varieties most noteworthy. Some of these had over two dozen blooms each. A short distance from the Cheshunt Roses were the Woking Clematises in a circular group. The plants were healthy and well trained, but as they had been shown for some time the flowers were rather past their best. Some good varieties were represented, the best single purples being Robert Hanbury, Princess of Wales, Marquis of Salisbury, Blue Gem, and Lady Caroline Nevill; double purple, Countess of Lovelace; single white, Maiden's Blush; and double white, Lucie Lemoine.

The tables occupied a considerable space, and were arranged in lines in the central transept. In the class for a dinner table set out for twelve there were five exhibitors, Messrs. Dick Radclyffe & Co., High Holborn, securing the first prize. In the centre of the table were three elegant glass stands, which contained chiefly Rhodanthes and Grasses at the top, below these being white Azaleas, Spiræas, and scarlet Bouvardias, the base being occupied with Anthurium Schertzerianum, white Azaleas, scarlet Pelargoniums, Spiræas, Ferns, and Begonia foliage, a few sprays of Lygodium scandens being twined round the columns of the stands. Near the sides of the table were small buttonhole glasses, and the fruit comprised Grapes, Apricots, and Peaches. Mr. Sutton Abbott, Nightingale Lane, Wanstead, was second with a somewhat similar arrangement, but containing several Ixias, Chrysanthemum Etoile d'Or, and Eucharises, the fruit being Cherries, Figs, and Apricots. Mr. J. R. Chard, Floral Dépôt, Clapham Common, was third, Fuchsias having been much too freely employed in his stands. There were also five entries in the class for a smaller table (for six persons). Mr. W. L. Buster, St. Mary's Cray, Kent, was placed first with a neat arrangement. The central stand contained flowers of Delphinium cardinale, Narcissuses, Grasses, Azaleas, and Ferns. Messrs. D. Radclyffe and Mr. J. R. Medland, Chelmsford Road, Woodford, followed closely, neither being of remarkable merit.

Bouquets were numerous. For a bride's bouquet there were five entries; Miss Annie Williams, Sutton House, Upper Holloway, being awarded the first prize for a very neat arrangement of white Azaleas, Tabernaemontana coronaria flore-pleno, Gardenias, Stephanotis, Lily of the Valley, and Adiantum cuneatum. Mr. W. Brown, St. Mary's Grove Nursery, Richmond, was a very close second, his bouquet being somewhat similar, but containing Bouvardias in addition. Messrs. Jones & Son, 7, Shoplatch, Shrewsbury, were third, Eucharises and Stephanotis chiefly characterising their design. For three bridesmaids' bouquets Messrs. Jones & Son were first and Mr. W. Brown second, both exhibiting well. Ball-room bouquets were contributed by four exhibitors. First, Messrs. Jones & Son, Shrewsbury, with combinations of Myosotis, Odontoglossum cirrhosum, Azaleas, and Eucharises in one; Maréchal Niel Roses, Oncidium concolor, and Bouvardias in another; and Lælias with Dendrobies in a third. Mr. A. Stuart, 84, Seven-sisters Road, was second; and Mr. W. Brown third. Flower stands were not very remarkable, though the competition was good. Messrs. Stuart and Buster and Miss Williams were the prizetakers. Mr. W. Brown was first with six buttonholes, chiefly Orchids and Rosebuds; Miss Williams was a close second; Miss E. M. Baines, Palmer's Green, taking the third and an extra prize for neat arrangements. Baskets were contributed by Miss Williams and Messrs. Medland and Stuart, who secured the chief prizes.

One exhibit that was not for competition deserves notice; this was a collection of artificial flowers from the Flower-girls' Brigade, 12, Clerkenwell Close, E.C. Some of these were admirably executed, Camellias and Narcissus flowers especially. Several really attractive bouquets were included in the stand.

### THE GOOSEBERRY CATERPILLAR AND CURRANT SHOOT GRUB.

ON page 188 of our issue of March 10th of the present year appears a reply from an entomologist to the letter of a correspondent, "COMBER," on the Gooseberry caterpillar. In reference to what appears on the page quoted we subsequently received the following letter, which may be appropriately published at the present time, seeing that we are on the eve of the caterpillar season.

"With all deference to your entomologist, I think his very full description of the Gooseberry caterpillar will not assist your correspondent 'COMBER;' but if 'COMBER' will refer to your issue of July 24th, 1879, page 76, he will find what he requires in your reply to 'W. D. M.' The plan of handpicking there recommended I have found the surest way, having practised it for many years and never failed to keep my trees free of this pest after the first

appearance; but allow me to supplement your reply to 'W. D. M.' by adding that when he discovers any leaves perforated, which is the first sign of the larva having come to life, to pull all such leaves off and destroy them. If 'COMBER' desires to test this plan he will not regret the time given in going over the trees, as so much depends on getting quit of the first hatching.

"As a guide for him to know the insect (*Nematus Ribesii*, or Sawfly), if he will refer to page 431, vol. xxii., or page 515, vol. xxv., of our Journal, he will find a full description with wood-cut illustration of the same. I have looked over the Journal since 1870 and find questions asked respecting this destructive insect in almost every volume; and the remedy given, with one or two exceptions, is to dust the trees with hellebore powder, which, being a poison, I think is not very desirable to use.

"P.S.—If 'COMBER' wishes to see what has been written in our Journal respecting the insect in question let him refer to the following vols.—viz., vol. xviii., page 404; vol. xxi., page 16; vol. xxii., pages 431 and 510; vol. xxiii., page 67; vol. xxiv., page 477; vol. xxv., page 515; vol. xxvi., page 516; vol. xxvii., page 14; vol. xxviii., pages 436, 472, and 435; vol. xxix., pages 91 and 136; vol. xxxi., page 68; vol. xxxvii., pages 76 and 295; vol. xxxviii., pages 317 and 422.—K. K."

We are obliged to "K. K." for his diligent research; and as all old readers have not preserved the back numbers, and as we have had many new subscribers of late, we reproduce the figure of the sawfly and remarks referred to, also the figure of the

Fig. 92.—Gooseberry Sawfly.

Current fly and grub, in reply to "A KENTISH INQUIRER," who desires some particulars respecting them.

"The green caterpillars which so soon strip off a Gooseberry bush's leaves are the larvæ of a sawfly. The cross lines show the natural size of this sawfly. This insect, which has been named by entomologists *Nematus trimaculatus*, *Nematus Ribesii*, *Tenthredo Grossulariæ*, and *Tenthredo ventricosa*, comes forth in the course of April. Its body is yellowish brown; its antennæ nine-jointed and brown; the crown of the head, eyes, three large spots divided by a light line on the back, and a large spot on the breast, are all black; the body or belly is orange; the wings reflect the colours of the rainbow; and their nerves, with a large spot on the front edge of the fore wings, are brown; the legs are brown also. The female lays her eggs along the principal nerves on the under side of the Gooseberry leaves, and less frequently on those of the Red and White Currant. The eggs are hatched within ten days, and the arrival of the caterpillars may be known from the leaves being eaten through into numerous small holes. These caterpillars are pale green, with one ring at each end yellow; the head, tail, feet, and rows of spots on their sides being black. Successional broods are hatched from the beginning of May until October, but it is during May and June that they are usually most abundant and destructive. Some of these descend into the earth from cocoons, and bring forth fresh flies at the end of the summer; but the later broods of caterpillars remain in their cocoons throughout the winter, and give birth to the earliest spring swarm of sawflies."

We have also received the following note from our entomological correspondent supplementary to his remarks on page 188—

"To what has been already stated in regard to the caterpillar of *A. grossulariata* I wish to add a remark accidentally omitted—viz., that it will occasionally feed upon a variety of plants in a garden, should scarcity of food lead it to wander from the species it prefers. I have found it upon the Rose, but usually it is reluctant to travel far. Another circumstance about it that is notable may be added—the insect is common 'in the open,' feeding often enough along the hedges and the borders of woods. Hence in country places gardeners are exposed to the arrival of moths into enclosed grounds which have not been bred there. Comparatively little damage appears to be done by the caterpillars during the autumn, hence they commonly escape notice then. Miss Ormerod

of Isleworth recommends forking up the earth and sprinkling in lime as the best remedy for this and the sawfly also."

As to remedies, we know that the plan recommended by "K. K." of promptly gathering all the perforated leaves is a safe one, but too tedious for many cultivators in this reduction-of-labour period. For preventing the caterpillar Mr. Diggles wrote as follows last March on preventing the Gooseberry caterpillar. "Boil some white hellebore powder in water and place it in a tub or garden engine, adding sufficient boiling water to syringe all the trees; when it is cold apply it on a dry day, to dry on the leaves as soon as the trees are in leaf immediately after blooming, and before the fruit has grown. One application is sufficient for the season, and does not injure the fruit. One pound of white hellebore powder is enough for sixty trees, and is best applied with a hand syringe. I have tried this plan for years and found it to answer." And Mr. William Taylor thus refers to his mode of extirpating the pest—"Hellebore powder, I observe, is strongly recommended by some of your correspondents for destroying caterpillars, but I will not run the risk of poisoning my employers, who eat Gooseberries very freely. The only safe and effectual remedy tried for caterpillars inside the Gooseberry house was fir-tree oil, and that was applied four times during the season, drenching the bushes all over by means of a syringe with a bent nozzle, at the rate of half a pint of the oil to three gallons of water. It is rather expensive to use in so large a way, but I do not expect to have so much trouble again, and I am in hopes of getting rid of the enemy altogether. One dressing was given after the Gooseberries were ripe, and that did not injure them, although applied during sunshine, the taste passing off in two or three days; but some Currants in the same enclosure were injured by using it on them after they were ripe, though it did not harm them in the earlier stages. I find that different samples of water make a very great difference to the efficacy of this insect-killer: that which is soft and has been exposed a long time to the air being the best, while hard water is almost useless. As a rule, I think the whiter the water turns when the oil is put to it, the more efficacious it is likely to be." Mr. Laxton shakes the bushes violently, or rather strikes the branches sharply, so as to dislodge the caterpillars; and when they are on the ground he covers them with soot, thus destroying the pest and manuring the trees by the same operation.

THE CURRANT-SHOOT GRUB.—Everyone acquainted with old gardens must have frequently noticed that one or more of the branches of the Currant trees tenanted them have suddenly withered and died without any apparent cause. In such cases, if the wood of the branch be split down the centre the pith will be found all consumed, the tube where it had been blackened, and nothing remaining but the excrements of a caterpillar, which may also be caught at his work of destruction if the examination is made so soon as the branch first shows symptoms of withering. This caterpillar is fleshy, whitish, with four yellowish brown spots near its head. It is the larva of the Currant fly (*Sphinx tipuliformis*, *Sesia*, or *Ægeria*, or *Bombecia tipuliformis*). The parent moth is beautiful, and may be seen at the end of May and early

Fig. 93.—Currant-shoot Grub.

in June during hot sunshine, either settled on the leaves of the Currant, or flying around the flowers of the Syringa and Lilac. It is about three-quarters of an inch across the wings when these are quite opened; the prevailing colour is bluish black, with various parts yellow; the antennæ black; the breast with a yellow line on each side; the abdomen, or lower part of the body, has three yellow rings round it in the females, and four in the males; the fore wings are barred and veined with black; it has a brush of fine scales at the end of its abdomen, which fan it can expand as it pleases. The Red, White, and Black Currant, and we think the Gooseberry, are all liable to its attacks. It lays its eggs in April in openings of the bark of a young shoot, and the caterpillar immediately it is hatched penetrates to its pith, and eats its way

down this until it reaches the pith of the main branch. The only remedial measures are to kill the moth whenever seen, and to split down the withered branches and serve the caterpillars similarly.

## NOTES AND GLEANINGS.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held last Tuesday, Major F. Mason in the chair, the following candidates were duly elected Fellows of the Society—viz., Miss Florence May Baird Smith, Colonel Blundell, Mrs. Bosman, Mrs. T. T. Bucknill, Alexander T. Cory, Dr. R. T. Daniell, Viscountess Folkestone, Sir George Macpherson Grant, Bart., M.P., Viscountess Harberton, R. Nasmyth Irving, H. Heming Johnson, Mrs. Henry Kent, Arthur Kimble, Mrs. Bonnor Maurice, Archibald Milman, William Pawley, J. Mostyn Pritchard, and Reginald Yorke, M.P. Major Higginson, R.H.A., and Mrs. Higginson, were elected guinea members.

— ON the old rockery at Kew one of the finest Forget-me-nots we have seen is now flowering; it is named MYOSOTIS DISSITIFLORA VAR. SPLENDENS, and is similar in habit to the well-known typical form, but is rather taller and more robust. The flowers are, however, considerably larger, some being half an inch in diameter, and the colour is an extremely bright clear blue. If the plant referred to is not an unusually healthy example, the variety is a valuable acquisition not only for the border or rockery but for growing in pots, as some specimens in the greenhouse at Kew well indicate.

— A NORWICH correspondent, "D. C.," writes as follows in reply to "G. O. S." concerning IXIAS:—"I would observe that, being natives of the Cape of Good Hope, they require a light open soil. Plant as late as possible and very early in December 6 inches deep in light soil. Do not cover them at all either with handlights or any other protection; they will come up quite soon enough without any assistance, and unless any unforeseen circumstance takes place every bulb will stand the spring, and by early summer they will be in perfection. Take them up in the autumn and lay them on the shelf of a hot greenhouse or in the sun, which is the temperature they undergo in their native habitats, where they enjoy a long period of rest. I have not lost a bulb this long trying cold weather."

— MR. W. CHARLEY writes as follows concerning PYRUS MAULEI—"On seeing 'W. K.'s' article in your last issue (page 393) I was rather disappointed that Pyrus Maulei was not included. Last autumn it was recommended to me, and I planted it in a shrubby border. This spring it has been covered with flowers and has been greatly admired. The tree is 5 feet high, the branches are pendant, and I think it deserves a better situation than a shrubby border. When it can be moved with safety I shall plant it out as a specimen."

— A LIST of PLANTS FOR DISTRIBUTION BY THE ROYAL HORTICULTURAL SOCIETY has been published, and it is stated that the Council are desirous that the privileges of the Fellows should be exercised to the utmost legitimate extent, in order that the cultivation of the most approved varieties of fruits should be promoted throughout the country for the public benefit. In former years plants were distributed by ballot, but on investigation the Council found the result was not satisfactory, as rare and valuable plants frequently fell into the hands of those who had not the proper appliances for their cultivation. Fellows are now entitled to select for themselves any plants which they

may desire to cultivate, and which, being the legitimate property of the Society, the Council are enabled to distribute. Every application must be in writing, and not more than one specimen of any variety or species can be supplied. Four-guinea Fellows and forty-guinea Life Fellows are entitled to select thirty plants, and two-guinea Fellows and twenty-guinea Life Fellows half that number. The list should be marked and signed by the Fellows and sent to the Superintendent, Royal Horticultural Society's Gardens, Turnham Green, who will forward the plants as may be directed, provided they are still in stock. Should any of the plants selected have been all distributed, others of a similar character may be substituted. The plants included in the list will be ready for distribution about the beginning of July, and will be distributed in the order in which the applications are received.

— THE CALCEOLARIAS AT BEDFORD HILL HOUSE, BALHAM, the residence of J. Brand, Esq., are extremely fine this year. The plants, about four hundred in number, as arranged in a house 100 feet long, have a remarkably rich effect. By careful selection and fertilisation Mr. Rapley has succeeded in establishing a strain of undoubted merit. The plants are not more remarkable for their large flowers of good form and varied colours than for their firm stout branching habit. Many of the plants need no stakes, and the growths have not once been stopped, yet the plants are as compact and sturdy as the most exacting cultivator could desire. Many of the flowers are 2½ inches in diameter, a yellow self of great smoothness exceeding that size, and the dark selfs and spotted forms are in all respects of superior quality.

— WRITING respecting GARDEN RANUNCULI, the Rev. C. Wolley Dod observes:—"Your correspondent in his notes on these last week omitted to mention one very ornamental plant, the double Ranunculus repens. This name may frighten gardeners who know it only as a most pernicious weed in wild shrubberies or new plantations, but it is easily kept within bounds on a border like other running plants by doubling back the runners to their parent, and so forming a compact mass of flowering heads. It bears flowers twice the size of those of R. acris on stalks half their height, and produces them freely."

— THE ROYAL HORTICULTURAL SOCIETY OF LIEGE announce that their twenty-eighth Exhibition will be held on the 24th to the 28th of July this year. Two hundred and six classes are provided for all the usual horticultural exhibits, 422 prizes being offered, consisting of gold, silver gilt, and silver medals of a total value of 11,265 francs. The chief distinguishing features are the number of classes for special exhibits, such as particular genera or families. These are arranged in the schedule under their great botanical divisions of Cryptogams, Gymnosperms, Monocotyledons, and Dicotyledons. Some of the most remarkable classes, or rather those which we are best accustomed to see in English exhibitions, are the following—Ten Gymnogrammas, six Platyceriums, twelve Cycadaceous plants, forty Caladiums, forty Marantaceous plants, a collection of Musaceous plants, and similar collections in Iridaceæ, Amaryllidaceæ, Bromeliaceæ, and Liliaceæ, with special classes for such Orchids as Cypripediums, Cattleyas, Vandas, Phalaenopsis, and Masdevallias. Other natural orders provided for are Piperaceæ, Euphorbiaceæ, Melastomaceæ, Myrtaceæ, Crassulaceæ, Apocynaceæ, Asclepiadaceæ, Solanaceæ, and Gesneraceæ. Bouquets, fruits, and garden implements have also several classes devoted to them.

— DURING the past and present week a great number of visitors interested in Orchids and rare plants generally, have inspected what was announced as a COLLECTION OF ODONTOGLOSSUMS AND MASDEVALLIAS AT MR. BULL'S NURSERY

AT CHELSEA. The display not only includes a rich assortment of the two genera indicated, but numerous examples of other Orchids, and these, arranged with great taste with ornamental-foliaged plants, form an exhibition of remarkable diversity and unquestionable attractiveness. The grand avenue of Cycadaceous plants and Tree Ferns in the winter garden forms a fitting approach to the brighter house beyond, in the centre of which are large specimens of the imposing Anthuriums Veitchi, Warroqueana, hybrida, and insigne, and a fine plant of the stately Aralia concinna. Around these and on the side stages intermixed with Asparagus plumosus, small Palms, and Sarracnias, are the Orchids. These include upwards of thirty forms of Odontoglossums, many of the varieties of *O. Alexandræ* being of great merit, and *O. Pescatoria grandiflora* of striking excellence, as also are many of the varieties of *O. vexillarium*, of which the number of plants is very great. Thirty forms of Masdevallias represented by numerous plants are also flowering, an example of *M. Russellianum* having 130 flowers. The others consist of the choicest kinds in cultivation. *Cattleya labiata Warneri* and *C. Mendelli elegans* are most beautiful, and *C. Mossiæ aurantiacum* and the finely frilled *C. Lawrenceanum* are extremely rich. The varieties of *Lælia purpurata*, *Bryasiana* and *rosea*, also command attention. Epidendrums are represented by *bicornutum*, *vitellinum majus* *prismatocarpum*, fine, and *Parkinsonianum*, all of which are in excellent condition, and the curious *Nanodes Medusæ* is suspended from the roof. This is a brief outline of an extensive and beautiful display, which is not likely to disappoint visitors who are enabled to inspect it. The exhibition, for exhibition it is, remains open throughout the present week.

— WE are informed that the REIGATE ROSE ASSOCIATION will hold their annual Show on July the 5th in the grounds of the Priory, Reigate, the residence of Lady H. Somerset.

— MESSRS. SUTTON & SONS have now a beautiful display of CALCEOLARIAS AT READING, one of the houses in their nursery being entirely devoted to those plants, which are excellent in every respect—dwarf, compact, robust, with fine heads of flowers and healthy foliage. The colours are surprisingly diversified. All the brightest and most delicate shades characteristic of the Calceolaria are represented, with several very distinct and attractive tints—one, a soft rosy purple, being especially noteworthy. The markings on the corollas are also greatly varied, some being heavily blotched with colour and others delicately laced or netted. In symmetry of form, size, and substance of flowers there is little left to desire, and still further improvements are now being effected in the habit and colours; and, owing to the careful attention bestowed upon selection of seed-bearing plants, some advance is notable every season.

— THE usual monthly meeting of THE METEOROLOGICAL SOCIETY was held on Wednesday, the 18th inst., at the Institution of Civil Engineers, Mr. G. J. Symons, F.R.S., President, in the chair. D. W. Barker, B. Jumeaux, W. Oelrichs, H. Porter, W. Roper, and Rev. G. R. Wynne were balloted for and elected Fellows of the Society. The following papers were read—"Comparison of Robinson's and Osler's Anemometers, with Remarks on Anemometry in General," by Richard H. Curtis, F.M.S. The author in this paper gives a very clear statement of the present state of anemometry, and points out the defects in Osler's and Robinson's Anemometers, which are the chief forms of recording instruments used in this country. "Notes on Waterspouts Observed at Cannes in January or February, 1872," by the Hon. F. A. Rollo Russell, M.A., F.M.S. "On some Swedish Meteorological Observations in Connection with the Return of the Seasons," by Alexander Beazley, M.Inst.C.E.

— THE lessees of the Alexandra Palace announce the fol-

lowing Horticultural Exhibitions to be held during the present season:—June 10th and 11th, Floral Decorations and Pelargoniums; June 17th and 18th, Strawberries and Cherries; July 2nd, Rose Fair and Gooseberries; July 8th and 9th, Rose Show.

## ROYAL HORTICULTURAL SOCIETY.

MAY 24TH.

NOTWITHSTANDING the near approach to the Great Show, there was by no means any falling-off in the number of exhibits at this meeting; on the contrary, not only was the Council-room well filled, but the conservatory also contained several large and handsome groups.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. W. W. F. Dick, Esq., Thames Ditton House, Surrey, sent a twin fruit of Rollisson's Telegraph Cucumber, for which a letter of thanks was awarded. Mr. W. Wells, Earlswood Nurseries, Redhill, sent Wells' Improved Cucumber, a cross between Telegraph and Blue Gown. It is a handsome Cucumber, and said to be very prolific, but the Committee did not consider it a novelty and superior to others in cultivation. Mr. G. Bethell, gardener to Sir Richard Wallace, Sudborn Hall, sent a seedling Melon called Bethell's Conqueror, a pink-fleshed, yellow-skinned, and finely-netted fruit, but the flavour was not of superior quality. Mr. Bethell also sent a Tomato called Sudborn Hall Perfection, which was considered very similar to Hathaway's Excelsior. Mr. Henderson, The Gardens, Thoresby, sent a dish of a Fig called Adam, a large and handsome green Fig, but as the Committee were not allowed to taste it they could give no opinion upon it. A cultural commendation was awarded. Mr. Miller, The Gardens, Clumber, sent a dish of James Veitch Strawberry of fine quality. Mr. Z. Stevens, The Gardens, Trentham, sent a Tomato in a pot called Trentham Early Fillbasket. It was found to be inferior in flavour, but as it was stated by Mr. Stevens to be a good bearer it may be useful for market cultivation. Mr. H. J. Clayton, The Gardens, Grimston Park, Tadcaster, sent a dish of Tomatoes. The variety was selected from Kaye's Early Prolific. The dish of six fruit weighed 3½ lbs., and the flavour was good. It was very much corrugated and coarse in shape. A cultural commendation was awarded.

FLORAL COMMITTEE.—J. McIntosh, Esq., in the chair. Messrs. J. Veitch & Son, Chelsea, exhibited a group of new plants, containing the following in addition to the Gloxinias, which were certificated and described below:—*Serissa foetida flore-pleno*, a dwarf plant with small bright green leaves, and double white tubular flowers about half an inch in diameter; *Pleopeltis albidula squamata*, a dwarf Fern with pinnate or trifoliate dark green fronds, bearing small whitish scales; *Croton recurvifolius*, with short recurved leaves, dark green, veined with red and yellow; and *Astilbe Thunbergi*, which was certificated, and is described below. Mr. H. Cannell, Swanley, Kent, exhibited a plant of the fine double scarlet *Tropæolum Hermine Grasshoff*, and flowers of *Tropæolum canariense* "improved," a very pretty variety with regular bright yellow flowers, each of the petals being blotched in the centre with maroon. The useful double white *Campanula persicifolia alba flore-pleno* was also represented by flowers and plants. A vote of thanks was accorded to Mr. Cannell for the Campanulas. Messrs. Rivers & Son, Sawbridgeworth, sent several seedling semi-double Zonal Pelargoniums.

The General Horticultural Company sent several new plants, among which were the following:—*Rhodea japonica aurea variegata*, a distinct variegated plant, certificated at the second spring Show of the Royal Botanic Society, and described on page 375; *Pteris serrulata cristata compacta*, a dwarf and neat form of this well-known Fern; *Rivina humilis variegata*, with racemes of bright crimson berries, small white flower, and variegated foliage. It was more like a form of *R. laevis*. *Philodendron Wallisi*, very pretty, already described; and *Pteris tremula* var. *crispa*, which is distinct from the ordinary form of *P. tremula*, the fronds being slightly waved. Messrs. J. Laing & Co., Forest Hill, sent a plant of a Tuberous Begonia named Thomas Moore; the flowers were of a great size, the larger petals being 2 inches in diameter, of a scarlet tint. A vote of thanks was accorded Messrs. James Carter & Co., High Holborn, for a basket of Carters' Queen's Prize Mimulus with very large flowers, the corolla bordered with rich crimson and maroon. Messrs. C. Lee & Son, The Vineyard Nursery, Hammersmith, exhibited three specimens of *Yucca elegans*, a neat and graceful form with narrow dark shining green leaves, rather more than 2 feet long and gracefully curved. Messrs. Barr & Sugden, Covent Garden, contributed a pretty collection of Daffodil and Iris flowers. The double white form of *Narcissus poeticus* was largely represented, and many other choice varieties. The charming little *Hyacinthus amethystinus* and its white variety were very attractive, resembling diminutive Scillas. Mr. W. Brown, Hendon, exhibited four varieties of decorative Pelargoniums, named Harry Buck, very large soft cerise, dark blotch in upper petals; Robert Green, very neatly formed flowers, brilliant colour with a tinge of scarlet; Enchanter, rather rough form but bright scarlet tint; and Stentor, with upper petals heavily blotched with black. The plants were all in vigorous health, and a cultural certificate was awarded. The Rev. H. Harpur Crewe, Drayton Beauchamp, Tring, sent a flower spike of an *Eremurus*, a native of Cashmere; the floral portion was about 8 or 9 inches in length,

the flowers being white and resembling some *Ornithogalum*s. It was referred to the Scientific Committee.

Mr. G. Parker, Winkfield, sent a variegated Zonal Pelargonium named Marian Harper, with numerous trusses of small pink flowers. Mr. J. H. Hawley, Ranelagh Gardens, Leamington, also sent a variegated pink-flowered Zonal Pelargonium, and a semi-double scarlet Zonal named Sir Charles. Mr. W. M. Crowe, Upton, Essex, exhibited two varieties of Tree Carnations—one, bright scarlet and very free, named General Roberts, the other salmon tinged with scarlet. Mr. J. Fry, gardener to J. Baker, Esq., Haydon House, Eastgate, Pinner, was accorded a vote of thanks for a stand of *Gloxinia* blooms of Veitch's strain, diversified in colour and of good form. Mr. Maurice Young, Milford, Godalming, sent flowering branches of the Snowdrop Tree (*Halesia tetraptera*), figured in this Journal in 1879. Mr. P. Wallace, Winkfield, near Windsor, was accorded a vote of thanks for a stand of twelve florists' Tulip flowers in excellent condition. Sir Charles Strickland, Bart., Hildeby, Malton, sent a plant of *Lælia majalis* on a block, and bearing two large flowers. Mr. Abbage, gardener to J. S. Bocket, Esq., The Hall, Stamford Hill, sent plants of *Calanthe vestita major* and *Trichopilia suavis alba*, the latter being certificated.

There was a pretty display in the conservatory, one of the principal groups being that from the General Horticultural Company, Warwick House, Regent Street, chiefly comprising *Dracenas*, *Crotons*, *Gloxinias*, and Ferns; many novelties were also included, and the plants were all in admirable condition, but no award had been made for them when we left the Exhibition. Mr. J. Aldous, Gloucester Road, had groups of variegated Maples, Fuchsias, Pelargoniums, *Ericas*, and Mignonette, for which a bronze Banksian medal was accorded. Messrs. Osborn & Sons, Fulham, S.W., staged a pretty group of hardy plants, including several new and choice plants. In the centre was a basket of the new variegated Ivy, *Hedera helix madeirensis variegata*, the centre of the leaf very bright green, with a broad white margin. *Spiræa japonica aurea* was also well represented, with plants of *Primula cortusoides amena*, the dwarf Phlox frondosa, *P. divaricata*, *Camassia esculenta tardiflora*, *Scilla patula*, *S. campanulata*, and many other plants.

Calceolarias formed a brilliant display. Mr. W. Rapley, gardener to J. Brand, Esq., Bedford Hall House, Balham, had a large group of handsome plants in admirable condition, the flowers being of great size and very bright colours. Some were remarkably richly marked with crimson or maroon, and the large yellow self certificated was especially noteworthy. A silver Flora medal was accorded. A similar honour was adjudged to Mr. J. R. Bird, gardener to J. A. Causton, Esq., Lodgemore, Alleyn Park, West Dulwich, who also sent a handsome collection of Calceolarias, comprising some fine plants with a great diversity of colours. The group was margined with *Gloxinias* and *Adiantums*, arranged alternately. The *Gloxinias* were generally in fine condition, the flowers large, and colours rich. Mr. Charles Noble of Bagshot sent a pretty group of dwarf Clematises comprising a number of handsome varieties. A purple-flowered variety named George Eliot possessed a very distinctly marked and delicate fragrance. A remarkably handsome semi-double white variety was also shown named Lady Constance Kennedy, one of the finest varieties in commerce. Other varieties especially noticeable were Imogene, white; Pirate King, dark purple; Aurora Leigh, large French white; Mary Queen, white with a faint puce tint; Countess Gleichen, white faintly tinged with blue; Alonzo, fine purple; Undine, double purple; Aurora, double puce; Proteus, similar but larger; and Lady Wallace Campbell, double white. Several others were also very fine, one unnamed seedling having pale purple flowers  $8\frac{1}{2}$  inches in diameter, and of excellent form. A silver Flora medal was awarded. Mr. W. Brown, Hendon, had a pretty group of decorative Pelargoniums, very healthy and flowering profusely; but the most noteworthy feature of his group was a dozen plants of *Crassula jasminea* in 48-pots, the large white flowers being tied up in the market style, the heads being nearly a foot across. A highly attractive and interesting group of Cape Pelargoniums was contributed from the Royal Horticultural Society's garden at Chiswick, and an ornamental group of Azaleas, *Schizanthuses*, *Saxifraga nepalensis*, with an edging of *Adiantum gracillimum*, *Gloxinias*, and *Selaginellas*. Messrs. Hawkins & Bennett, Twickenham, sent a bunch of Lily of the Valley named Victoria; the bells were of great size, but probably that is due to their superior culture. Mr. Guyett, gardener to Mr. Perrett, Lynton House, Clapham Common, had a pretty group of miscellaneous plants, and was awarded a silver Banksian medal.

For the following plants first-class certificates were awarded—

*Gloxinia Lady Marriott*.—This and the two following were shown by Messrs. J. Veitch & Sons. An erect-flowered variety, with neat blooms spotted with crimson and evenly margined with white. *Fabiola*.—Fine flower, spotted on the throat; centre of corolla lobes soft crimson, broad white margin. *Brantane*.—Very distinct. Flower of good form, medium size; throat netted or spotted with purple, fading to violet and white; margin faintly dotted with a light shade.

*Astilbe Thunbergi* (Veitch).—A Japanese plant with large pinnate leaves; the pinnules elliptical, serrated, and 3 to 4 inches in diameter. The flowers are white, and produced in large spreading panicles or compound racemes, on which they are closely placed. It is an elegant plant, and will no doubt become a general favourite.

*Reseda odorata flore-pleno prolifera alba*.—Mr. W. Balchin, nurseryman, Hassocks Gate, Keymer, Sussex, obtained a certificate for this

very remarkable Mignonette. The flowers are globular in form, comparatively large, and very full of narrow white petals; and at the side of each flower a small shoot appears, which is said to become elongated and bear flowers successively after the old one has faded. The spikes are 3 to 6 inches in length and thickly clothed with flowers, which possess a strong and agreeable fragrance.

*Rubus deliciosus* (C. Lee & Son).—A beautiful hardy shrub, bearing abundance of large white blossoms something like a single Rose. The petals are broad, and though the individual flowers are of rather short duration they are produced so freely that the plant appears to be literally "a mass of bloom." A specimen at Kew in the herbaceous grounds is now remarkably fine, and well indicates the character of this valuable shrub.

*Calceolaria Cloth of Gold* (Rapley).—One of the finest varieties we have seen in regard to size of flower. These are a bright sulphur colour, and average from  $2\frac{1}{2}$  to 3 inches in diameter, being of proportionate substance. The plant shown was in a 48-size pot, and bearing several handsome trusses of flowers.

*Trichopilia suavis alba* (Bockett).—A pretty pure white variety of the well-known type. The lip is large with a dash of yellow in the centre, but otherwise quite devoid of colour, as are also the petals and sepals. Each plant was bearing several flowers.

*Clematis W. E. Gladstone*.—This and the two following Clematises were included in Mr. C. Noble's group in the conservatory, and were there observed by several members of the Floral Committee, who unanimously awarded certificates for them. The one named above has remarkably large and handsome flowers of excellent form and substance; some were fully 9 inches in diameter, the sepals being proportionately broad and of good form. The colour is pale purple, lighter in the centre of the sepals.

*C. Lady Constance Kennedy*.—Flower pure white and semi-double—that is, with two series of broad petals. Very free, and altogether a beautiful variety.

*C. George Eliot*.—Remarkable for possessing a very distinct fragrance, considered by many to faintly resemble Violets. The flowers are of medium size and excellent form; colour bright purple.

SCIENTIFIC COMMITTEE.—*Sarracenia Popei*.—In this species Mr. W. G. Smith remarked that the stigmas was quite closed, and the petals completely hid the stamens, so they could only be seen after the petals had arisen in the way described at the last meeting.

*Ontario Poplar*.—Dr. Masters exhibited an injured specimen, supposed to be affected by some insects, which, however, could not have caused the injury. Sir J. Hooker remarked upon the rapid growth of the Ontario Poplar, and that it was particularly liable to decay.

*Gynantherous Wallflower*.—Specimens of this well-known malformation were forwarded by Mr. Leipner from the Bristol College, in which the stamens are changed to carpels.

*Lilium Martagon*.—Specimens found growing near a wood of Pinus Pinaster, near Croydon, were sent by Mr. Stokoe, who raised the question whether it was wild or not at that locality, intimating that the seeds might have been brought by birds.

*Banksia Fruit*.—Dr. Masters exhibited a specimen from which seeds had been taken fifteen years old, which had germinated and grown into robust plants. They were raised by Mr. J. S. Cousins. Colonel Clarke observed that he has raised Peas after keeping them in pods for ten years.

*Cryptomeria elegans*.—Dr. Masters exhibited a specimen with cones.

*Coherent Buttercups*.—He also exhibited three Buttercup flowers coherent, though the flower stalks had not united immediately below them, though they were coherent at the base. Mr. W. G. Smith remarked that he once figured a Fir tree which had two leaders coherent into one.

*Primula Stuartii*.—Mr. M. Foster exhibited a flowering plant from North-west Himalayas. *Iris statella*.—He showed this species from the Botanical Garden of Palermo. It is allied to *I. italica* and *pseudopumila*, but ovary is distinct from both. The origin was unknown, possibly being a hybrid. It was received from Todaro. He also showed a bud of *I. erratica*, allied to but is smaller than *I. lutescens*. He exhibited a pod of *I. tectorum* full of seed, the result of self-fertilisation. Colonel Clarke remarked that Cowslips crossed by Primroses would often cause the ovary to swell, but there might be no seed formed—a fact long ago observed by others, as by Max Wichera on Willow, as recorded in the Horticultural Society's Journal. He also made remarks on the dispersion of *I. Evanesca*, that it only was found east of North America, from Florida to Lake Ontario; that it is found in China and Japan and as far as Nepal, but then ceases.

*Eremurus*.—A fine spike of white flowers was exhibited by Rev. H. H. Crewe of an unknown species of this genus from Cashmere. A botanical certificate was awarded. He showed the following species of Tulips:—*T. maculata*, *oculis-solis*, *spatulata*, *scabris-capæ*, *Didieri*, *viridiflora*, and *carinata*. Sir J. Hooker remarked that considerable doubt had been expressed as to whether any of the supposed wild species about Florence were not really escapes from cultivation.

A communication was read with reference to the proposed removal of the Herbarium of Florence from its present excellent site and building to a much more disadvantageous one, and a general expression was made as to the undesirability of the change.

LECTURE.—The Rev. G. Henslow took the Pelargonium as the subject of some remarks, as there was a fine display of species and rare varieties from the Society's Gardens at Chiswick. He alluded to the earliest species introduced in 1632, named *triste*, and called in John-

son's "Gerard" *Geranium indicum*. It was brought by Mr. John Tradescant. Linnaeus called the genus *Geranium*, but L'Héritier changed it to *Pelargonium*, as the structure of the flower differs considerably, being irregular, having the usually seven fertile stamens united by their filaments, and a long tubular neetary adherent to the pedicel; whereas *Geranium* is regular, has ten stamens, and no tubular neetary, but honey glands instead. He showed drawings to illustrate the vast difference between the original type and the latest improvement acquired by horticulturists. These began about the year 1812 in England, many species having been introduced before that date. Thus, before 1732 six species were grown at Eltham. In 1812, 102 species were in England, but after that date experiments by crossing began, and were published regularly by Robt. Sweet till

1830, the improvements being in size and colour, the long narrow petals changing to a round Rose-leaf-like form; veins disappeared, and a clear broad mass of colour appearing on the two upper petals. The present multitude of forms is now subdivided into groups, such as the large-flowered section, the Zonal section, variegated, and double-flowering varieties, &c. Amongst the many species and varieties exhibited was *P. inquinans*, which had given rise to the "Nosegay" scarlet forms, several Ivy-leaved white, double, &c., the crisped-leaved and seented group; but it appears difficult to trace back the origin of the large-flowered kinds to the original species which gave rise to it. A plant with pink flowers and variegated foliage, exhibited by Mr. Parker, was remarkable for the great tenacity of its petals. This appeared to illustrate the principle of "compensation,"

Fig. 94.—*CRATEGUS COCCINEA*. (See page 424.)

which the lecturer had more than once described, for the pollen was very scanty and inefficient, the loss in that direction being counterbalanced by the firmness and tenacity of the petals.

The lecturer next commented upon the corollas of *Geranium* and *Erodium*, which are regular, while that of *Pelargonium* was irregular. He suggested that the latter condition, which was for the most part found in axillary flowers and those which are situated to the side of plants, while regular flowers are terminal. The irregularity has probably been brought about by the visits of insects, and when irregular flowers are perpetually fertilised by artificial means they not unfrequently reassume their regular character. This is seen in *Pelargoniums* and *Gloxinias*. With regard to the structure of the

flower the lecturer entered into details, showing the peculiar differences in the methods of fertilisation both in *Pelargoniums* and in true *Geraniums*. Thus, while in the common scarlet, and especially the paler varieties, such as the pink Christine, the anthers mature simultaneously with and stand about the stigmas, so that it fertilises itself with great ease; other forms, such as the Oak-leaved or Lemon-seented, is strongly "proterandrous"—i.e., the anthers mature, shed their pollen, and even fall off before the five branches of the stigma are ready to receive the pollen, which they must do from another flower. In this instance the antherless filaments retire and hang down, while the stigmas now rise up and occupy the exact position maintained by the anthers previously. The lecturer then illustrated

similar conditions in *Geraniums*. Thus, in *Geranium pratense*, our largest-flowering wild species, both the sets of five stamens mature before the stigmas. In *G. pyrenaicum*, which has a smaller flower than the last, the first set are over before the pistil matures, which it does simultaneously with the second set of stamens. In *G. molle* it is the same, only the corolla is still smaller; but in *G. pusillum*, which has the smallest flower of any, the pistil matures first and the stamens afterwards. This condition is called "proterogynous."

Mr. Henslow then explained how, as he believed, this has come about. That whenever a flower has a large corolla, well-developed stamens, and much pollen it will be found to be proterandrous, simply from the fact that those outer whorls require so much nourishment that the pistil is delayed in its development. In proportion, however, as the corolla and stamens are relatively small then the pistil is enabled to mature more rapidly, and even to precede the development of the stamens, and thus become proterogynous. He next called attention to the honey nectary which forms a long tube adherent to the pedicel, and compared it to the "spur" of *Tropæolums*, in which plant it was free and not "adnate" to the stalk, a character which separated these so-called *Nasturtiums* from *Pelargonium*, both belonging to the same tribe of the family *Geraniaceæ*. The peculiar character of the fruit called for some remarks. The carpels separating in *Geranium* from a central beak-like prolongation of the axis by curling upwards, but in *Pelargonium* and *Erodium* the carpels twist also, forming a long spiral-like awn. This is extremely hygrometric and uncoils when moistened, the use being, as Dr. F. Darwin has shown, to enable such fruits to bury their seeds by the upper part catching amongst the leaves of plants, and so securing a *point d'appui* when the "awn" uncoils in wet weather, and screws its sharp-pointed fruit into the ground.

#### CRATÆGUS COCCINEA.

NEARLY two centuries have elapsed since this tree was introduced to our gardens from North America, and yet it is by no means frequently seen in gardens and pleasure grounds. We much fear that, owing to the crowding system of planting shrubberies that has been fashionable during the past few years, many deciduous flowering trees have not been permitted to develop in a natural manner and arrive at a satisfactory flowering state. Many deciduous trees that would have been objects of beauty if space had been afforded them have been crowded out and cut away to make room for some formal Conifer, as the best mode of rectifying errors in planting! We should like to see greater discrimination in planting trees in the positions that are most suitable for them, and to see more well-grown specimens of beautiful flowering trees associated with evergreens, and on the fringes of ornamental plantations. *Cratægus coccinea*, so named from its scarlet fruit, is a most distinct and attractive spring-flowering tree, and a good specimen never fails to command admiration. The figure on page 423 represents the character of the species. Both the flowers and foliage are large, and a tree 15 to 20 feet high, with its natural round head, forms one of the finest ornaments of the pleasure ground during April and May.

#### OLD AND NEW PEACH TREE TRAINING.

MR. SIMPSON, writing under this heading (see page 393), thanks "SINGLE-HANDED" for his information concerning old authors who have advanced the "extension system in Peach culture." After a little criticism on the illustrations in the "Gardener's Assistant" Mr. Simpson gives us a statement of the produce of "four young Peach and Nectarine trees planted in 1878." It is unfortunate that he did not state distinctly how many of the trees were Peaches and how many Nectarines, for the sake of getting a proper estimate of the results of each. I think he should have been more explicit in the heading, too. Might I ask him which is the old and which is the new system of Peach-tree training?

Mr. Simpson invites those who have been so long ahead of him in the cultivation of the Peach to furnish him with particulars referring to the fertility and training of the trees. I have made it a rule for the last thirty years or more to leave the young wood its entire length at pruning time. I thin and cut out all the weak and useless branches not required, and train the trees in fan shape. I disbud early in the season, and if the terminal bud is not strong and healthy I disbud to the next strongest. I often use lateral shoots to fill up when required, but not otherwise. In disbudding I leave all the shoots requisite on the upper side only, having them as near the base as possible. I have no difficulty in keeping the trees well furnished with healthy young wood to the bottom under this system of training; I believe it to be the oldest, and the shortening of the shoots to be of a later date. I am sorry I cannot oblige Mr. Simpson with the information asked for referring to the fertility of young trees, but I have often gathered from three hundred to four hundred fine fruit from a tree grown as stated, and on walls outside.

In conclusion I might say that the system I have shortly described has been practised to my knowledge in most places in this district for more than twenty years, and this controversy cannot fail to "amuse" many, though they lack the courage of appearing in print.—A. LINDSAY, *Ditton Park, Slough, Bucks.*

I HAVE much pleasure in giving my old friend Mr. Simpson the information he asks for in last week's issue respecting the fertility of Peach trees trained on the system I described in the *Journal of Horticulture* a short time since. In doing so I take this opportunity to inform him, that when I wrote the paper referred to I was not aware that he had published a book on the cultivation of the Peach. My paper was in the hands of the Editor of this Journal before a notice of his book appeared in any of the gardening periodicals. My sole reason for writing was to prove that what is now called the "extension system of pruning and training the Peach tree" was not new, as has been supposed by some. The system has to my knowledge been practised for years before Mr. Simpson was born, and practised by me for more than twenty years! Mr. Simpson will, I am sure, excuse anyone in possession of these facts being "amused" at the articles that have appeared on this subject lately, and say with the wise man of old, "There is nothing new under the sun."

In old-established gardens the building and planting of Peach houses are of rare occurrence, and it falls to the lot of few gardeners to carry out such work. A gardener might live in a place all his life and not have the opportunity of doing either, as Peach trees properly managed will keep in good bearing condition for a much longer time than that; so that comparatively few gardeners will be in a position to supply Mr. Simpson with the desired information respecting the fertility of young Peach trees grown in houses. Were I to speak of my experience as a young man, I might say I was never fortunate enough to be at a place where a Peach house was planted during the time I was there, and my experience was not confined to one or two places, but to many. I made it a rule to see as much as possible and to learn all I could, and never to remain longer in any place than two years.

It fell to my lot some ten or fourteen years since to plant a Peach house 60 feet in length, 14 feet wide, and 16 feet high. At the time of my taking charge of the place I found the house considerably out of order. The trees were trained partly on an old turn-over trellis and partly on a trellis on the back wall. I had the trees and trellises all taken out, the house repaired, and a new trellis put up close to the roof. After making a new border four young trees were planted. They grew rapidly, producing good crops of fruit, and in four years they completely filled the house, and have continued to bear heavy crops of fine fruit yearly ever since. I also had a new house built here six or seven years ago and planted with four trees, which filled the house and produced 112 dozen fine Peaches in three years after being planted. I might say that the fruits were not counted on the trees, but counted as they were gathered to send away.

In order to answer Mr. Simpson's question I instructed my indoor foreman and one of the young men in the houses to count the Peaches on one of those trees on Friday last. A Royal George was chosen. The Peaches have thoroughly finished stoning some time since, and are now swelling off for the last time. I had string run up the tree from bottom to top at regular distances, and I told my men to be careful in counting, and each was to count separately all the fruits in the enclosures. After careful counting it was found that the tree was carrying a crop of no less than twenty-eight and a half dozen Peaches.

A gardener of experience and ability, and one whose opinion I value much at all times on gardening and other subjects, called on me a few days ago. While looking at the Peach trees referred to he said they were without doubt four of the finest Peach trees for their age he had ever seen in England, Scotland, or Wales.—A. PETTIGREW, *Castle Gardens, Cardiff.*

#### HENRY JACOBY PELARGONIUM.

As bedding-out is now in full progress let me recommend all who are able to do so to try a small bed of this brilliant semi-Nosegay variety. It is in my opinion without doubt one of the most valuable forms for massing that has been introduced during recent years. The plant is of free growth, yet dwarf, and is very floriferous; the trusses are good, and the petals adhere to them better than those of many varieties do, while the colour is of the most glowing crimson imaginable. It is richer than Charles Smith, and the plant is dwarfer than Charles Schwind, both of which are valuable for decoration in or outdoors. Henry Jacoby is also equally valuable for cultivation in pots. Well-grown examples in 5 or 6-inch pots have a very rich appearance in

summer in greenhouses or on window sills; while for winter decoration, and for affording bright cut flowers in the dark days, I do not know of one variety to surpass it. Those who are fortunate in having a few plants of the variety in question will do well to increase the number, and those who do not possess Henry Jacoby will not err by adding it to their collections, as, unless I am mistaken, it will become a standard Zonal for general decorative purposes. It is comparatively new, yet is not expensive, and may be had from the leading florists. If I were in the trade I should work up a stock and advertise it, as I feel certain it would do me credit. This very promising variety was raised by Mr. Pearson of Chilwell.—A LONDON PARK MAN.

#### VINES FROM LAYERS.

THERE is not, in my opinion, any system of raising young Vines now practised and recommended which possesses so many advantages as layering. Vines may be raised from layers in half the time usually required to obtain them from eyes. Those now being raised from eyes have no doubt been growing for the last three months, and they will continue to need attention for the next five months, and by that time probably not one in twelve will be sufficiently developed to bear fruit next season. If cut back and grown on again for another year they may be expected to show some bunches about the time they are twenty-four months old, but when layered a crop may be had from them in half that time or less.

At the present time we have a few Black Hamburgh Vines in pots bearing six and eight bunches, and these Vines were not rooted at this time last year. At the end of May some of the strongest shoots left near the base of the established Vines were layered to afford Vines for fruiting in pots this season, and they have done so well with so little trouble that many of your readers might try the plan with advantage.

Most Vines produce shoots from the base of the stems during the growing season; many gardeners rub these off as soon as they appear, but if they are allowed to grow a few yards long they are well suited for layering the following season. Being near the ground they need not be trained amongst the other shoots, but be tied across from stem to stem. Such a shoot will be found to mature sound eyes, which will start strongly into growth the following spring; the shoots then formed will be strong and short-jointed, and when they are a few feet in height they will be ready for layering.

This operation is very simple. A number of 6-inch pots should be drained and filled with a mixture of loam and manure, and each of these must be placed directly under the Vine shoot which it is desired to layer. A small notch is then made underneath each shoot on the old wood, and this part is placed in the soil in the pot, and a short thick wood peg is placed over the rod immediately on each side of the young cane and fixed in the soil; this keeps them firm until roots have been formed, which will quickly take place if care is taken to prevent the soil becoming dry. The young growths are still sustained by the old Vine, and the layering gives them no check, but it is well to stop each one as they become about 6 feet in height. This is a good length for a pot Vine, and by taking the point out of them then it causes them to swell. The young Vines may be left attached to the old rods until the pots have become quite filled with roots, and after being separated for a few days they may be transferred to 10-inch pots, and with good attention they will form fine fruiting canes the same season.—A KITCHEN GARDENER.

#### ROYAL BOTANIC SOCIETY.

MAY 25TH.

THE first Summer Show of the year was favoured by excellent weather, and the result was not only a beautiful display but a large attendance of visitors. The exhibits filled the large marquee and the corridor, the arrangements being generally satisfactory. The following is a brief report indicating the chief features of the Show and the most successful competitors.

*Stove and Greenhouse Plants.*—These were well represented. In the nurserymen's class for twelve Messrs. T. Jackson & Son, Kingston, secured the first prize with large and healthy specimens, all flowering freely. Messrs. B. Peed & Son, Lower Streatham, were second with good specimens, including a fine *Statice profusa* and *Allamanda grandiflora*. In the amateurs' class for ten Mr. W. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley, was deservedly accorded the first prize for healthy specimens, including a very fine *Aerophyllum venosum*, *Tremandra ericæfolia*, and *Erica depressa major*. Mr. Tudgey, gardener to J. G. Williams, Esq., Henwick Grange, Worcester, was a very close second, also with large plants. Third, Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, with an even collection, *Aphelexis macrantha rosea* being

well flowered. For an amateur's six Mr. W. Chapman was first with fine specimens of *Dracophyllum gracile* and *Erica Cavendishii*, large, even, and well flowered. Mr. Tudgey was again a close second with smaller but neat plants; and Mr. J. Child, gardener to Mrs. Torr, Garbrand Hall, Ewell, was a good third. An extra prize was deservedly awarded to Mr. J. Hinnell, gardener to F. D. Davis, Esq., Surbiton. Messrs. J. Jackson & Son, Kingston, were first with handsome specimens; Messrs. B. Peed & Son second with healthy *Aphelexis* and *Heaths*; and Mr. Henry James, Castle Nursery, Norwood, third with small plants in the corresponding nurserymen's class.

*Orchids.*—A magnificent bank of Orchids was contributed in the two classes devoted to them. In the amateurs' class for twelve Mr. J. C. Spyers, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, was first with very beautiful specimens. The finest were *Dendrobium Bensonianae*, *Odontoglossum vexillarium*, *Cattleya Warneri*, with fourteen large flowers; *Cattleya Mendelli*, with twenty flowers; *Cypripedium niveum*, and *Calanthe veratrifolia*. Mr. J. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, Ilford, was a close second, a fine variety of *Dendrobium Wardianum* and a large specimen of *D. nobile* being represented. Mr. Henry Hcims, gardener to F. A. Philbrick, Esq., Oldfield, Bickley Park, was a good third, *Sobralia macrantha* being very fine. In the corresponding class for nurserymen Mr. B. S. Williams, Upper Holloway, was awarded the premier prize for a beautiful specimen of *Cypripedium barbatum* with over forty flowers; *Lælia purpurata*, very fine variety with twenty flowers; *Oncidium concolor*, *Epidendrum vitellinum*, and many others in fine condition; Mr. Henry James and Messrs. Jackson & Son followed, both staging good specimens.

*Azaleas.*—Many fine Azaleas were shown, and taking them generally they have rarely been in better condition. For an amateur's six Mr. A. Ratty, gardener to R. Thornton, Esq., The Hoo, Sydenham, was first with tall pyramidal specimens, well furnished with flowers. Mr. Child was second with smaller but equally well flowered plants. Mr. G. Wheeler, gardener to Lady Louisa Goldsmid, Regent's Park, was third with fairly good specimens. In the corresponding nurserymen's class Messrs. Jackson & Son secured the chief position with neat, healthy, globular-trained plants, Mr. C. Turner, Slough, following very closely. For six Azaleas in 12-inch pots Mr. Ratty was first, Mr. Child second, and Mr. Wheeler third. In the open class for twelve specimens Mr. R. Ratty was the most successful exhibitor, having bright and vigorous plants and securing the chief prize. Mr. C. Turner was a close second with well-flowered plants; and Messrs. Jackson & Son were third. An extra prize was awarded to Mr. Wiggins, gardener to H. Little, Esq., Uxbridge, for neat specimens.

*Fine-foliage Plants.*—As usual several fine groups of these were exhibited. For six specimens (nurserymen's class) Mr. B. S. Williams was first with a good selection of plants, Mr. Henry James following with small plants. In the amateurs' class Mr. H. Cole, gardener to J. Lawless, Esq., Exeter, was first with a handsome *Gleichenia rupestris glaucescens*, *Livistonia altissima*, and *Alocasia intermedia* among others. Mr. C. Rann was a good second with a fine collection, including two remarkably fine *Crotons*, *C. Andreanus* being particularly handsome. Mr. Tudgey was third with healthy examples of *Pritchardia pacifica* and *Kentia gracilis*. An extra prize was awarded to Mr. Wheeler for some good specimen Palms among other plants. For six exotic Ferns (nurserymen's class) Mr. B. S. Williams was first with handsome *Gleichenias* and other choice Ferns. In the amateurs' class for the same number Mr. G. H. Cole was placed first with fresh healthy specimens, *Davallia Mooreana* being especially fine. Mr. Douglas was second.

Messrs. Paul & Son, Cheshunt, were the only exhibitors of nine Roses in pots, securing the first prize for grand plants similar to those shown at Alexandra Palace recently. Mr. C. Turner was the chief exhibitor of six *Pelargoniums*, and was adjudged the first prize. Mr. Wiggins, Tottenham, was second for neat plants with very large flowers. Mr. J. Wiggins taking a similar place in the amateurs' class, followed by Mr. C. Hammond, gardener to F. Huntly, Esq., Stamford Hill.

Miscellaneous exhibits were numerous and of excellent quality. A silver-gilt medal was awarded to Messrs. James Veitch & Son, Chelsea, for a large and handsome group of Roses in pots arranged with small Maples. The Roses were in excellent condition, and were greatly admired. Mr. B. S. Williams, Upper Holloway, was awarded a silver medal for a pretty group of miscellaneous flowers and fine-foliaged plants, including several novelties. A large silver medal was adjudged to the General Horticultural Company for an imposing group of new and choice plants, chiefly *Dracænas* and *Crotons*, both remarkably well coloured. The margin of *Gloxinias* and *Adiantums* was also pretty. A silver medal was secured by Messrs. Wm. Cutbush & Son, Highgate, for a novel and effective group, comprising variegated Maples, *Abutilons*, *Myosotis*, white Daisies, Lilies of the Valley, and small *Heaths*. Some examples of *Erica Cavendishii* were especially notable for the vigour and the number of large flowers they bore. Messrs. Richard Smith & Co., Worcester, were awarded a silver medal for a collection of *Clematises* in fine condition, several bearing large flowers. Messrs. George Jackman & Son, Woking, contributed a handsome group of *Clematises*, comprising twenty fine plants, the flowers large and colours good. A silver-gilt medal was awarded. A silver-gilt medal was adjudged to Messrs. Paul & Son for a large group of Roses in pots—fresh,

healthy, and well-flowered. Many plants were certificated, and will be described next week.

### CARPET BEDDING.

THE design for a carpet bed, which is shown on fig. 95, is quite different in style to the one published last week. Provision is made for a large groundwork of green, which is always a pleasant relief for the brighter colours. A proposed mode of planting is

Fig. 95.

submitted, but the arrangement can be varied according to the plants at command. As will be seen, a choice of plants is afforded for some of the panels, any one of which will be suitable for the positions indicated.

1. *Alternanthera amœna*.
2. *Sempervivum montanum*, *Pachyphytum bracteosum*, or *Kleinia repens*.
3. *Leucophyton Brownii*.
4. *Pyrethrum* (Golden Feather).
5. *Mentha*, *Herniaria repens*, or *Veronica Loudoniana*.
6. *Alternanthera* of any kind.
7. *Meibomiaanthemum cordifolium variegatum*.
8. *Alternanthera amœna*, or any other dark variety.
9. *Echeveria secunda glauca*, or *Sedum glaucum*.

### THE FRUIT CROP.

I AM very glad to see that Mr. Taylor is interesting himself as to the amount of damage done to hardy fruit trees by excessive

winter frosts. All know of the damage done to shrubs and evergreens. It is my opinion that the damage is not so serious this year as last, the wood being in better condition; but it is a very great mistake to suppose that all Apples and Pears can stand 39° of frost during winter with impunity. But that some varieties can stand it I readily believe. Now is the time to make our observations. Understand, it is not the actual embryo fruit bud that is injured by severe frost in winter, but it is injury done to the wood that prevents the sap flowing to support the young fruit that results in the crop failing. The tender Pears I have no hope of, but the Hesse and such Apples as Lord Suffield I have little dread of. Let us all be careful observers, and be slow to be of that army always to the front with their variable excuses. To read some reports one would be led to think that Nature had made no provision whatever either against winds, rains, or other climatic changes. Here we have had rather severe frosts lately: but as all was dry Apples, Pears, and Gooseberries were not in the slightest injured.—JOSEPH WITHERSPOON, *Chester-le-Street, Durham*.

### KITCHEN GARDEN.

EVERY crop is in a very backward state, and yet the germination of seeds has been wonderful considering the ungenial weather. Every effort should be made to keep the hoe at work in dry weather between the rows of root crops, so that the growth may not be impeded by weeds. Sow late Peas in a well-enriched piece of ground. Ne Plus Ultra and Emperor of the Marrows are fine varieties. Continue to earth-up and place sticks to advancing crops of Peas as they become ready. Broad Beans also should be slightly earthed, and a successional sowing made. Sowing Beet must not be longer deferred, and there is yet time for Scorzonera and Salsafy. Another sowing of Scarlet Runners may be made between now and the beginning of June, also Dwarf Kidney or French Beans. Turnips owing to the dry weather have suffered from the Turnip fly, but this has been kept under by dustings of quicklime when the plants were wet with dew. A sowing of Cauliflowers should be made from the 20th to the 24th for late use, and for lifting to plant in frames to afford a supply in severe weather. As Potatoes advance in growth keep the soil drawn up to them, and if necessary, where they are planted wide, fork between the rows, and plant out Brussels Sprouts, &c. Seed of Sweet Basil, Sweet Marjoram, and other herbs may yet be sown on a sheltered border. Chicory for affording roots to be placed in a Mushroom house to give blanched heads for winter salading, should now be sown in rows 12 to 15 inches apart, thinning to 9 to 12 inches distance. Asparagus-cutting will be in operation daily, and if it be necessary to have recourse to cutting any that will be required for forcing, it must not be continued for a long period, or the roots will be so weakened as to be unfit for forcing next season. The planting-out of early crops of Celery may be proceeded with in beds 4½ feet wide, placing the plants across the beds 12 inches asunder, in rows 15 inches apart. Make successional sowings of Turnips, Spinach, Radishes, and Lettuce to insure the succession unbroken. Rhubarb should have all flower stems removed, and in order to secure a fine growth supply liquid manure liberally, and mulch with partially decayed manure. Seakale also should have any flower stems and any blanching material removed when the heads are cut, and the ground pointed over. Attenuated crowns may be cut back with advantage. Mulching or surface dressings 2 or 3 inches thick of partially decayed manure is a commendable practice, especially in light shallow soils, and is of great benefit to Peas, Beans, Cauliflowers, and other crops.

Supply water liberally to Carrots in frames, and draw out when ready every alternate one. Supply water and liquid manure to French Beans in pots or in pits abundantly, and keep the pods closely picked. Forward in pits or otherwise the growth of Capsicums, shifting them into larger pots as necessary, and keep them free from aphides. Harden Tomatoes in frames preparatory to planting them out of doors. Proceed with planting out ridge Cucumbers

and Vegetable Marrows, affording if possible the protection of hand-lights. As frames become cleared of early crops of Potatoes utilise them with Cucumbers or Melons.

#### HARDY FRUIT GARDEN.

The recent frost (12° during the night of May 12th), has not been so disastrous as might have been expected, for the soil was dry and the foliage more forward than when the blossoming occurs earlier. Growth is now rapid, and will necessitate prompt attention in stopping or removing the foreright shoots of Apricots, and side shoots not required for extension. Lay in young growths for filling vacant space or displacing parts that have become bare of spurs, which if not now bearing fruit may at once be cut out, or as soon as the fruit is gathered, and any attenuated spurs may be shortened to growth at the base. Keep a strict look-out for caterpillars. Attend betimes to thinning the fruit, leaving the finest and best situated for ripening. If the trees are in small borders and the soil is dry mulch with manure after giving a thorough supply of water, and assist trees carrying a full crop of fruit with liquid manure. Plums against walls will soon require attention; indeed disbudding foreright growths will need immediate attention, and any overgrown spurs may be cut back so as to encourage those better situated. Peaches and Nectarines are producing fine healthy foliage, and should as soon as practicable have the disbudding completed and the growth regulated as indicated in our last calendar. Promptly apply an insecticide if aphides appear, and apply flowers of sulphur should mildew be noticed. Cherries promise well, and should have attention in disbudding or stopping foreright shoots, and making provision for filling up vacant spaces. Carefully examine the foliage of fruit trees, destroying caterpillars if any exist, which soon disfigure both foliage and fruit. Nut bushes are frequently injured by caterpillars, this being a good time to search for and destroy them. An abundant crop of Gooseberries and Currants appears assured and so far are clean, but nevertheless frequently examine for caterpillars, and whenever they appear dust at once with freshly ground hellebore powder. Disbud and regulate the young shoots of Vines where they are trained to walls, and if mildew appear have recourse to sulphur. Do not overcrowd the growths, but train so as to admit plenty of air and light. Mulch bush and pyramid fruit trees with good manure, especially weakly trees in light soil, and if dry weather prevail supply water freely. Recently planted fruit trees should be mulched with short littery manure, and have a good watering. Strawberries should be mulched with littery manure, and in dry weather have copious waterings. Fruit for dessert should have the trusses supported with sticks, so as to keep it from the ground and insure superior quality by exposure to light and air, and if extra fine fruit is wanted thin them, leaving only the finest. Strawberry plants that have been forced and the fruit gathered should as soon as possible be planted out, firming the soil well about them, giving at least one good watering, and these if kept free of weeds and runners will produce an abundant crop of fruit next season.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—Desirable as are the very early Peaches they do not as a rule set well, and for size and quality are not comparable to the older varieties, such as Royal George, Grosse Mignonne, Noblesse, Violette Hâtive, Stirling Castle, and Late Admirable. Acquisitions, however, are Hale's Early and A Bec, which set well and finish satisfactorily; Early Grosse Mignonne is also valuable. In Nectarines Lord Napier is a capital kind, swelling to a good size and coming much in advance of Elruge and Violette Hâtive, which are unrivalled for forcing. Trees in the earliest house from which the fruit has been gathered should have the bearing wood cut out, so as to admit of that for next year's crop having the benefit of light and air. There must not be any deficiency of water at the roots, and syringing must be practised twice a day to keep down red spider. The trees started early in the year have the fruit well advanced for ripening, and any leaves overhanging the fruit should be drawn aside or shortened so as to admit of the fruit colouring. Still continue syringing in fine weather until the fruit commences ripening. Clear rain water only should be used; hard water leaves a deposit on the fruit and is a great blemish. In the succession houses tying down

the shoots and thinning the fruit will now be the principal routine required. Give the inside borders some liquid manure occasionally during the time the fruit are in their first swelling, removing the covering material from external borders, and if at all dry give a thorough watering with tepid water, and in the case of weakly trees or those carrying a full crop afford liquid manure at 80°.

*Cherry House.*—The fruit is now quite ripe, and when the whole crop is in that condition the object will be to preserve them fresh and plump for some time. Shading should not be resorted to unless prolonging the season of supply be very desirable, or the foliage or position of the trellis is such as to expose the Cherries to the direct rays of the sun: under such circumstances it will be beneficial. A free circulation of air should constantly prevail in the house, and in dry hot weather damp the borders occasionally. There must not be any neglect in watering, and as soon as the Cherries are gathered recommence syringing the trees. Trees in pots will require daily attention in watering, and do not remove them from the house until the buds are well formed; then stand the pots on a bed of ashes in a sunny position, surrounding the pots with ashes, which will prevent the sun's rays acting on the roots.

## THE BEE-KEEPER.

### LAW ON BUILDING DRONE COMB—OVER-SWARMING.

MANY thanks for your sound advice to me for introducing a Ligurian queen. That advice I followed, and made an artificial swarm out of the straw skep I told you of, and the new queen was accepted all right. I now desire to ask when I can make another swarm from the same skep. It has its old queen yet, and is very strong. The last one, on the 13th inst., was made by removing the old hive and putting the new one on the old stand. Would you advise me to drive the queen with them this time, or would you advise me to give them a comb containing Ligurian eggs from the one introduced on the 13th inst.? These are things I am thinking of, but would like to have your opinion. In fact, I would venture to suggest that questions as well as answers should be printed. It would greatly help readers to understand the answer and apply it to their own case.—COMBER.

[Our correspondent's suggestion that the publication of queries *in extenso* would often help the reader to understand the reply more fully, we take to be perfectly accurate, and we have in consequence sometimes followed this course. We believe, in addition, that interest would be increased and a new light thrown often upon practical apiculture were our correspondents occasionally to give us their experience in following our or any advice, even if it be but the relation of a failure. For, as in moral matters "by the faults of others wise men correct their own," so in matters practical the failure of others may often be the occasion of our success. But to our correspondent's query.

We know from long experience that great increase in numbers is decidedly inconsistent with honey yield, and should therefore recommend that the frame hive and the skep be both now devoted to surplus gathering. It is easy to multiply stocks during the summer, and the temptation thereto is likely perhaps to make us overlook the fact that in doing this we shall have actually to feed while others are getting supers filled, and that after all when autumn is closing we may find ourselves, even if we are more than beginners, with many weak stocks instead of a few strong ones. As winter draws nigh uniting would, in these circumstances, become necessary, and quickly our large number of colonies sinks to fewer than we should have possessed had we been contented with a normal rate of increase. "In all labour there is profit," says the wise man; but the profit with us would have to take the intangible form of experience, the gain of which would make us better managers in the future. In our hearing, not long since, an American owner of 350 stocks was asked how colonies were to be made most profitable. His instant reply, "Keep as few as you can," though brief, contained not a little wisdom. As many bees, but as few colonies as possible, is undoubtedly the line along which alone large profits can be made.

If the skep in question be strong in numbers, and our correspondent is anxious rather for stock than supers, a second swarm may be made not earlier than about a fortnight after the taking of the first, which was done, we must remember, by confining an

imported queen in a cage in a frame hive and then placing this hive on the stand of the skep, which going to a new station was made to yield up all its flying bees to form a swarm, of which the Ligurian queen became the head. One plan suggested, however, in our correspondent's letter would not answer. It is giving a frame of Ligurian brood in a hive and placing this upon the stand the skep is now occupying. Of course the flying bees would constitute a swarm as before, and would raise in due time a queen from the Ligurian brood. All seems at first sight as it should be, and some books actually recommend this plan for making a swarm, but it is utterly bad notwithstanding.

It is a law with the bee that in the absence of a queen only drone comb shall be built, so that in this case the whole of the cards made during the first fifteen or sixteen days would encumber the hive with that which could be only used for store or for raising an unnecessary horde of consumers. So perfectly uniform is this instinct, that should bees build comb during the time a queen is caged amongst them awaiting their acceptance, the size of the cells formed will determine whether they are friendly disposed or not. If the former, they, regarding themselves as possessing a queen, build worker cells; if the latter, in the determination to raise a queen and reject the one offered them, they build drone cells.

If our correspondent can provide the made swarm with combs, or can furnish their frames with foundation the objection vanishes, for foundation\* settles the size of the cell and prevents even queenless stocks from building any but those of worker size. If it be especially desired to raise a queen from the Italian rather than the English brood, the old plan may be repeated of removing the queen from the swarm and placing her in a cage on the stand of the skep. She would be accepted as before, while the first-made swarm would raise queen cells in sufficient numbers to supply several for use elsewhere, but without any egg-laying for twenty-five days it would be quite unlikely to yield any surplus. The queen may be driven from the skep, but the successors there raised would be black, while the other plan at the worst would give hybrids.]

#### ARTIFICIAL SWARMING BEFORE DRONES APPEAR —PREVENTION OF CASTING.

PLEASE let me know if I can take an artificial swarm if I have seen no drones issuing from the hive; also whether the hive is as likely to throw off a second swarm at the end of ten days after taking an artificial swarm as if they had swarmed naturally.—BRIXTON.

[Drones in our hives are not important if other stocks at not more than half a mile or so possess them. At this date drones abound, and unless your position is one of complete isolation so far as bees are concerned we should regard the question of drones at home as not worth consideration, except as seeming to show that your hives are weak and not ripe for swarming. When bees are getting ready for natural colonisation drones are always raised, and artificial swarming should conform as far as possible to natural conditions. A few years since we raised nineteen Italian queens at once; and though we did not possess a black drone while Italians were in strong force with us, every one of our queens made a misalliance and produced hybrid workers. The probability of easting or sending out a second swarm is the same after artificial as natural swarming. Its prevention consists in cutting out all queen cells save one. This should be finely formed, and may be known to be approaching ripeness by the nibbling of the end by the workers, by which the wax sealing is removed. In skeps it is not possible to perform this operation with any certainty.]

#### COMBS BETWEEN FRAME AND HIVE—EVIDENCE OF QUEEN—EXTRACTOR AND HEATHER HONEY.

If you can advise me I should feel very thankful. My bar-frame hive is not in very good working order, as the bees have built down between the frames and hive box. What is the reason of this? One of my skeps, I fear, has no queen, but should like to be satisfied on this point. The workers do take in pollen, but very sparingly. I turned up the hive a day or two ago; it appears to be full of bees and moderately heavy. Do you think there may be a queen cramped for room owing to there being no breeding space? if so, what should I do? I bought an Italian queen, which did not reach me till too late for insertion. I kept her nearly three months, but workers sent with her appeared to be slaughtered by a large grub which I found in the small box in which they

\* This does not always apply to flat-bottomed foundation, for they sometimes build drone cells upon worker stamped sheet.

came. The queen was the last bee left, when she also disappeared. Why is it not possible to extract heath honey from bar-frames by means of the extractor? Is the extractor of use at all times with other honey in newly made combs?—A. CABBON.

[The frames must be too small. Their sides should reach the hive wall within three-eighth inch base. In this space no comb will be built. By inverting your skep you can at once see whether you have sealed brood, the brown rounded caps of which cannot escape attention. Finding this, you would know that your hive, even if without a queen now, possessed one less than three weeks since. By a little device you may, even with your skep, search successfully for eggs and grubs. Take a piece of thin looking-glass about half an inch square and fix this at an angle of 45° at the end of a stick or wire, leaving the face of the looking-glass unobstructed. Now, placing the skep so that the light shines down between the combs, draw the latter apart with the fingers and insert the looking-glass. It will reflect light into the cells and show in itself the condition of them most clearly. Eggs and larvæ in all stages may in this simple way be clearly seen. As your skep is strong we should recommend you to super it at once, when, if the queen be crowded-out of the brood nest by honey, the bees will soon make room for her by carrying the excess aloft. Excess of pollen is sometimes a cause of mischief, when transferring to a frame hive would be the better course.

The supposition that the bees with your imported queen were "slaughtered" by the big grub the box contained is incorrect. These grubs feed on comb, and possibly at times profit by the juices of the bee larvæ they meet in their path, but the adult bee is not injured by them.

Heath honey, but heather honey only, appears to contain a gelatinous substance allied to, if not actually identical with, the pectin of fruits. The consistency of Damson, Plum, and Currant jelly is due to substances, members of what are known to chemists as the pectose series, amongst which pectin appears. The question is one of great complexity, and at present analysts are not able to give any very exact particulars in reference to it. This gelatinous substance, however, so toughens the honey in which it is present that the extractor is usually unable to throw it out. New combs are too tender and delicate to admit of the handling and whirling which extraction involves. Those which have been hardened by the addition of many sets of pupæ cases will, however, pass through the ordeal with but very trifling injury. This the bees at once repair, so that the number of times which a comb may pass through the extractor is practically unlimited.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*]

#### TRADE CATALOGUES RECEIVED.

E. S. Miller, Wading River, New York, U.S.A.—*Catalogue of North American Perennials and Lilies.*

E. G. Henderson & Son, Maida Vale, London, W.—*Catalogue of Bedding Plants.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Seedling Auricula** (*F. W. Sanders*).—It is a very good border flower, and we have not a doubt it will have a fine effect in beds, especially if it is grown in masses. We shall be particularly obliged if you can inform us of its parentage, and when the variety first flowered.

**Summer-pinching Plum Trees** (*A Stranger*).—We do not quite understand the condition of your trees, as in one sentence you state, "the spurs are a foot from the wall," and in another you say, "they have been closely pruned in." You, however, will not err by entirely removing the foreright growths and others that are badly placed, and stop the remainder at about four leaves, commencing with the strongest shoots. Plums, however, generally produce a number of short-jointed stubby growths; these are the most fruitful, and many of them require little or no stopping. As a rule it is advisable, when the trees have covered their allotted space, to remove the most luxuriant growths for these are

long-jointed and do not readily form fruit buds at the base, the more moderate growths being far more fruitful in character.

**Raising Border Plants from Seed** (*Subscriber*).—*Anchusa italica*, *Delphiniums*, *Foxgloves*, *Honesty*, *French Honeysuckles*, *Foxgloves*, *Canterbury Bells*, *Sweet Williams*, *Seabious*, *Wallflowers*, *Valerian*, *Hollyhocks*, *Phloxes*, *Antirrhinums*, and *Potentillas* will answer your purpose, and are readily raised from seed sown now in drills in the open garden. The soil should be fertile, and if the weather is dry the drills must be well watered before the seed is sown. It will be well if the drills are drawn sufficiently deep that in covering the seed lightly they are not filled to the original level, as water cannot well be given to the rows afterwards. "Select" rock plants are not raised from seed; yet such plants as *Aubrietias*, *Arabises*, *Calandrinia umbellata*, *Saponaria ocymoides*, *Alyssum saxatile*, *Campanula carpatia*, *Alpine Auriculas*, *Violas*, and *Primroses* may be readily obtained from seed, and the plants are suitable for mounds and rockeries.

**Show Pansies for Exhibition** (*L. I. K.*).—Show Pansies are divided into three sections—yellow grounds, white grounds, and selfs, which terms are self-explanatory. We name six good varieties in each section:—*Yellow Grounds*,—*Alexander Brodie*, *Captain Clutie*, *Robert Burns*, *Senator*, *Corsair*, and *Daniel Robertson*. *White Grounds*—*Mrs. Hampton*, *Miss Todd*, *Jane Grieve*, *Bessie Wyatt*, *Mrs. Henderson*, and *Minnie*. *Selfs*—*Erebus*, *George Rudd*, *Dux*, *G. L. Brown*, *Helen Douglas*, and *Beacon*. Show Pansies are distinguished by symmetry of form, substance of petal, and clear, firm, and well-defined colours; fancy Pansies by their larger and less circular flowers and gorgeous colours. If you visit a show where both classes are represented you will see at a glance the difference that exists, and will never forget it. About the end of August or early in September is a good time for propagating Pansies. At that time fresh, short, non-flowering growths spring from the base of the plants, and if these are inserted in moist yet gritty soil under handlights on a cool shaded border they will speedily root, and make finer plants and give larger flowers than when propagation is effected earlier from strong flowering growths. Rooted offsets can usually be severed from the plants in September, and if planted deeply in good soil they form good plants by the following spring. Cuttings with hollow stems never make good plants nor produce fine flowers.

**Oyster Shells as Manure** (*B. Davy*).—Oyster shells, and all other shells ground to powder are useful manures, for they contain the same ingredients as bones, only in different proportions, the carbonate of lime or chalk predominating. We have seen them used with great benefit and in large quantities mixed with a heavy garden soil. The owner, after the ground was dug or forked, spread the powdered shells an inch or two thick along the lines where the crop was to be inserted, forked the powder in, and then sowed or planted the crop. The shells crushed fine are also useful for employing with soil for potting.

**Mulching** (*S. Travers*).—The placing of a covering of manure on the surface of the soil during dry weather is a most valuable practice. The ground should be well watered before the covering is applied. If manure cannot be had, fern or litter of any kind, or short grass from lawns, may be placed between the rows of vegetables where the soil is light and shallow. Cocoa-nut fibre refuse is valuable for placing on flower beds, as it is neat in appearance and very efficient in preventing evaporation. A layer quite 2 inches thick should be spread on the beds. Surface dressings of manure may be 3 inches in thickness, and light littery material 4 or 5 inches. We have found excellent results by systematically spreading the grass from lawns in the Celery trenches, as the covering kept the ground moist and lessened the necessity for watering the plants.

**Tuberous Begonias** (*Amateur*).—As you procured the seed from a "good firm" we presume it was also good, and its failure to germinate must be attributed to some fault of your own. But are you sure it has not germinated? We once examined some seed pots that had been covered with moss by an amateur who complained that he had been supplied with bad seed, but we found unmistakable evidence that the seed had germinated, and that the growth had been destroyed by the thick covering of moss which was left too long unmoved. You, however, do not complain of the seed, nor do we assert that it has germinated, though it ought to have done in the temperature in which the pot was placed if the soil has been "always kept moist." A sunny window would be one of the worst of positions for raising plants from such small seed; a shaded position would be much better, but we think you have small chance of success of the seed growing that was sown early in March. Tuberous Begonias usually succeed best when shaded from the mid-day sun; the plants require watering carefully yet sufficiently in their young state, but when the pots are filled with roots copious supplies are indispensable.

**Watson's Lawn Sand** (*E. L. B.*).—We have seen it used effectively on lawns, destroying the Daisies without killing the grass; we have also seen other instances where it was not so effectual. The cause of the different results we have no means of knowing; possibly the state of the weather when the dressings were given had an influence on the matter. The instructions that are issued with the sand state that it should be applied in calm dry weather, as rain washes out its strength. On ordinary soils  $3\frac{1}{2}$  ozs. per square yard is the quantity recommended for dredging on lawns, and on porous soils 4 or 5 ozs.

**Pears and Plums for Growing under Glass** (*W. B. Wall*).—Both Pears and Plums do well as double cordons; but if you train them as you propose up the roof at 1 foot apart sufficient light would not be admitted after a few years to allow of trees being grown on the back wall, although they would afford good results for some time. We should prefer to have the trees trained to trellises across the house so that their ends face the sun at noon, for we presume your house has a south aspect, commencing 4 feet from the walls back and end, and preserving that distance between each trellis. This would allow of the back and end wall being available, and give space for four trees to each trellis, and two rows of horizontal cordons in front where the roof is low. The cross trellises should reach from the ground to the roof. Pears most likely to succeed are Clapp's Favourite, Williams' Bon Chrétien, Souvenir du Congrès, Beurré de l'Assomption, Louise Bonne de Jersey, Comte de Lamy, Beurré Superfin, Baronne de Mello, Doyenné du Comice, Durendeu, Marie Louise d'Uccle, Passe Colmar, Beurré Diel, and Van Mons Léon Leclerc. Of Plums—Joly Green Gage, De Montfort, Jefferson's, Kirke's, Green Gage, and Coe's Golden Drop. The foliage of Jefferson Plum has not in our case the smell of Sweet Briar.

**Annuals and Perennials for Spring** (*B. L., Leeds*).—Of perennials that you may raise from seed there are *Alyssum saxatile compactum*, *Arabis alpina*, *Aubrietia green*, *A. purpurea*, *Bellis perennis* (Daisy) vars., *Campanula carpatia* and its white variety, *Wallflowers* in variety, *Iberis sempervirens*, *Myosotis sylvatica*, and *Pansies*; and of annuals, without giving an extended list, there are *Silene pendula* and its white variety, *Linnanthus Douglasii*, *Collinsia bicolor*, *C. verna*, *Saponaria calabrica* and its white variety, and *Nemophila*

insignis. The perennials should be sown from now to July, the earlier the better, pricking them off when large enough to handle in good rich light soil in an open situation, shading and keeping moist until established, then expose fully, planting-out in October where they are to flower. The annuals should be sown in an open situation late in August or early in September, and transplanted to the beds or borders in October, or about six weeks after sowing.

**Fruiting Young Vines** (*Excelsior*).—Your desire to excel is commendable, but it is well to make sure the road is safe before "going ahead of the slow coaches," as you say you intend doing. In our own practice, and as observed in that of many others, we have seen fine well-ripened wood made the first season, and from that we have taken, and seen others take, a good crop the second season after planting, but we never did so without regretting it afterwards. Fruiting a young planted-out Vine heavily has much the same effect upon it as fruiting heavily a young Vine in a pot. The first heavy crop from a young Vine paralyses it for future effort. It is the best and the most profitable in the long run to take from a Vine but little the second season after planting. The more roots the Vines make before bearing, the better will the Vines stand bearing fruit.

**Lifting Vines** (*J. A., Dublin*).—The lateness of the Grapes this year is doubtless the result of the long period of cold weather that has prevailed, and a large number of cultivators are in this respect in a similar position to yourself. Your proposed mode of draining the border is good, as also is your plan of lifting the roots in the outside border this year, and those in the inside next year. Provided the work is done with great care, having the soil ready so that replanting can be done quickly, the roots being kept moist and the foliage syringed and shaded to prevent flagging, the best time for lifting would be soon after the crop is cut, and fresh active roots would then be produced the same season; but it is of great importance that the roots are not dried during the process of lifting, and that the foliage is kept fresh. If you adopt this plan you must commence at one end, take out a portion of the old border, place in the new soil, and finish each Vine as the roots are raised, not dig the whole of the border out at once. This plan is perfectly practicable, and you ought to have no difficulty in doing the work, as the inside roots will be of great advantage in affording support to the Vines during the progress of the work outside. We are quite unable to advise you on the question of building a wall round the border, as your description of the soil "not very good" is far too vague to enable us to judge of the necessity or advisability of confining the roots in the manner indicated. It is necessary to have more precise information as to the nature and depth of the soil and the character of the subsoil in considering a question of that kind; it would have been an advantage, too, for the purpose of our reply to have known the width of the outside border. We may, perhaps, usefully remind you that the lime and brick rubble will not prevent the roots passing through into the subsoil, and that the drain must be below the bottom of the drainage, not merely below the top of it; and we may also remark that a wall, if the bricks are not laid in cement or very strong lime mortar, will not confine the roots, as they will pass through joints made of common mortar, and they will also pass under the wall if the bottom of the border is not concreted. If you think it desirable to send us further particulars, and ask any questions that this reply may suggest, your letter shall have careful attention.

**Figs Dropping** (*J. S. S.*).—Had you stated the size of the trees and the number of fruits on each, as well as the dimensions of the tubs, we should have been better able to have judged whether you are correct in your surmise that the cause of the evil is "want of root room." In all probability this is so, as the soil you have employed and the general treatment to which the trees have been subjected are correct. If you stop the young shoots, or such of them as have a tendency to become luxuriant, and surface-dress the soil with rich manure 3 inches in thickness, fresh roots will speedily form and gather the support that the trees need for maturing the crops. If your trees are at all large liquid manure once a week is not sufficient, and it should be supplemented with manurial mulchings. A few pieces of slates inserted round the sides of the tubs will afford space for the top-dressing, and for preventing the water that is applied passing over the tops of the tubs.

**Roses in Pots Failing** (*J. B.*).—It is no "trouble" to us to answer questions, but, on the contrary, a pleasure, when we can answer them usefully. You can scarcely expect to rival Mr. Taylor in growing Tea Roses in pots, as you lack the conveniences that are at his disposal, and your experience as a cultivator differs somewhat from his. But we may inform you that the gardener mentioned would not succeed so well as he does if he had to commence with plants similar to those you describe: yet he would not have failed so completely as you appear to have done. In the first place, he would not necessarily have repotted the plants as soon as he received them, and it is certain he would not have watered them with liquid manure as you have done before the roots were in an active state and had filled the pots. Nowhere in this Journal has the practice been recommended that you appear to have adopted. As a rule, the practice of repotting plants as soon as they have arrived from the nursery is not sound, and it is certainly prejudicial to plants to apply liquid manure almost immediately after potting, when the soil, as in your case, was quite rich enough for the requirements of the plants for many weeks. We fear you have first taken care to procure suitable soil for your Roses and then spoiled it with liquid manure. We advise you to visit a nursery in early October where dwarf Tea Roses are grown, select a dozen plants and pot them in 7, 8, or 9-inch pots according to the size of the plants, and if these are kept healthy and clean, and not started into growth too early, they will afford you more blooms than fifty such plants as those you have described. Plants grown to a flowering size in pots by a nurseryman who devotes special attention to Tea Roses would be better, but necessarily more costly, than plants grown in the open ground. Growing Tea Roses from a small to a large state in pots can scarcely be well done by amateurs with only one greenhouse at their disposal, and this in all probability not suited for the purpose. Had you wintered your plants in a frame and retarded their growth, then planted them in the open ground in March, you would in all probability have succeeded much better than by retaining them in pots and potting and starting them so early in the season, which was too early considering the means at your disposal—that is, if we understand the nature of your house aright; but on this point you do not supply any information.

**Insects on Melons** (*Duke Melon*).—Plants in such a state as yours are can only be cleansed by sponging every leaf with nicotine soap or some other insecticide, then syringing thoroughly, and dusting with tobacco powder. Questions arriving on Wednesday morning can only be replied to very briefly, or the answers deferred until another issue.

**Names of Plants** (*J. C.*).—No. 1, *Cupressus torulosa*; 2, *C. sempervirens*; 3, *Thuja Lobbi*; 4, *Cupressus Lawsoniana*; 5, *Biota orientalis aurea*; 6, *Taxodium sempervirens*; 7, *Retinospora plumosa aurea*; 8, *Cupressus Lawsoniana erecta viridis*; 9, *Abies Nordmanniana* (*G. O. S.*).—A spike and a better example of the foliage of the bulbous plant would have enabled us to have

given the name definitely; we can only now suggest that it is *Ornithogalum exscapum*. It is quite impossible to name the Saxifrage without flowers, as many species are so nearly identical in foliage that no one can name them from leaves alone. (*W.C., North Devon*).—Small imperfect leaves of Ivies are quite insufficient for identification; sprays containing perfectly developed leaves are necessary. (*R. L. D.*).—The flower appears to be a white variety of *Hyacinthus amethystinus*, and is very pretty. (*J. P.*).—1, *Lonicera tatarica*; 2, *Staphylea pinnata*.

**Swarming** (*F. J., Cork*).—The course you desire is the one we had planned. Swarming will be treated somewhat fully in an early issue.

**Moths in Hives** (*T. E. L., Needham Market*).—When bees during summer become weak from any cause, the combs they are unable to cover are likely to get infested with the grubs of some species of *Galleriæ*, the products of the eggs laid by the moth which by stealthy watching gains admittance. These grubs channel their way through the comb, and sometimes so carve and weaken it as to cause it to drop. But your bees in bringing out the moth larvae show that they are gaining strength, for ejecting the pests is an indication that they are repairing their combs. The preventive of all this is keeping your stocks strong, when the mother moth would have no chance. The moths whilst striving to gain an entrance have an advantage in that they as night-flying insects see clearly in the gloom, but in strong stocks the mother once within has but a poor chance of escape, while even if eggs are laid by her they are certainly removed before mischief has really commenced. Watching for the moths as you suggest would be quite useless, but they may often be seen flitting about if a lantern be taken after dark amongst the bees. Swarms having on more comb than they are able to cover are in no danger whatever. The precaution of killing all larvae and chrysalids will of course be taken.

#### COVENT GARDEN MARKET.—MAY 25.

No alteration in prices. A brisk trade doing, with large supplies of fruit from the continent.

#### POULTRY AND PIGEON CHRONICLE.

#### THE CROSS-BREEDING OF CATTLE.

THIS subject is of far more importance than is usually considered, and is well worthy of the attention of practical men as well as of physiologists. Experience in the matter, however, exhibits so many contradictions and unlooked-for results that attempts to lay down any sure guide have for the most part in general been received with considerable distrust by farmers, and more especially by young men, or the home farmer who may be just starting in his occupation; for no sooner does the inquirer imagine that he has discovered some particular principle which obtains generally, than he is met by circumstances which apparently upset his previous conclusions. This must be considered as very discouraging, especially to men of limited experience. For instance, the maxim that "like begets like" is a rule having extensive sway, yet as propagation is the work of two parents the respective influence of the one or the other is a matter involv-

ing considerable diversity of opinion as well as actual results; it therefore prevents anything like certain conclusions being arrived at. We cannot perhaps do better at the outset of our subject than consider the respective influence of each parent, at least the opinions held thereon by some of our most practical as well as scientific men, for on this the merits of pure or cross-breeding must principally depend.

The most probable and generally received opinion is that propagation is done as it were by halves, and thus it is considered that the back, loins, hind quarters, general shape, skin, and size follow one parent, and the forequarters, head, vital and nervous system the other; and we may venture to add that the former in the great majority of cases go with the male parent, and the latter with the female. There is, however, a minority of cases in which the opposite result obtains; still there is no great difficulty in showing one most important point—that size is governed more by the male parent, a matter which we must ask the home farmer to remember in considering the various proposals we shall lay before him in our future observations on crossing and the various objects to be obtained thereby. We have dwelt on this point rather strongly, because upon it rests the difficulty of effecting required improvements in breeding by means of crossing, and the still greater difficulty of establishing a new breed by such means. So formidable is this difficulty that breeders, in many instances finding their efforts at such improvements so often baffled, or observing this to be the case in the practice of others, cling with great tenacity to the doctrine of purity of blood, believing it to be the surest way in which to proceed with safety. Now, pure breeding when carried to an excess is styled in-and-in breeding, which has its advantages as well as disadvantages. Its friends and supporters say with great truth that when we have in breeding reached great excellence it is unreasonable to risk the loss of it by crossing, and the more so as the defects of a parent may disappear in a first or second, and reappear in the third or fourth generation, by "breeding back" as it is commonly termed. Again, it is urged, and with some force, that great excellencies can only be perpetuated by union with similar excellencies, and that beyond all this there is a certain amount of advantage from an unstained lineage, from the very possession of breed, as it is designated. The objectors, however, to in-and-in breeding declare that by so doing we engender weakness of constitution, diminution of size, hereditary diseases, and a tendency to barrenness; but it is again urged in reply to such objections that they occur from want of care and caution in weeding out defective animals in respect of both constitution and size. We have also to consider the ultimate objects of cross-breeders, for they vary much. Some require to improve their animals, keeping in view chiefly the value of the animals for dairy purposes; others desire to obtain an additional excellence in the animals they breed for fattening, and also to rear animals complete enough in all requisites for exhibition stock.

We must, therefore, now consider what qualities are required in the ox; these we may presume are early and rapid growth, the development of flesh or muscle on the parts most prized for human food, and also a disposition to lay on fat. These, with the possession of the smallest amount of bone consistent with strength and health, are the principal characteristics of a well-bred animal capable of being reared upon the esteemed point of early maturity and weight for age. Again, instead of the highly nervous temperament of the buffalo and other wild cattle, we have here a quiet lazy disposition; in fact, a lymphatic temperament, by the influence of which the digestive organs reign supreme, and convert for the profit of the breeder and feeder a given quantity of food into the utmost amount of flesh and fat.

We have no doubt, after falling back upon our own experience

as well as that of many eminent cattle breeders, that examples in pure breeding in cattle are more frequently met with, and of greater perfection, than in sheep. For instance, the Devon and Hereford cattle have descended through many generations in unbroken lines, and owe in a great measure the perfection which they have attained to careful selection by men of great eminence in cattle-breeding, who have given much attention, and in some cases made it the unceasing object and pleasure of their lives, to rear, improve, and possess them in all their native purity. The Shorthorns—although considerably of more modern origin, and brought into their present form by a series of successful crosses—have yet been preserved pure with even more care than the other breeds we have mentioned. The magnificent frame and great feeding properties of the Hereford, the quality of beef and richness of cream as well as working capacity of the Devons, are well known and generally appreciated; and with all these qualities they are quite unable to resist successfully the encroachments of the Shorthorns, whose early maturity and property of laying on both flesh and fat, accompanied by deep milking capacities, are so much esteemed that they outnumber both the other breeds combined. As, however, it is found in practice that the leading purpose for which a breed of cattle is kept is generally well defined, or ought to be, whether for the purpose of the dairy or for feeding and fattening upon the lines of early maturity, or for working purposes, and as each of these purposes can be well attained by keeping a pure breed, and maintained by judicious selection, there is certainly not the same temptation or inducement to enter upon a course of crossing, which is often experienced and prevails in sheep-farming, in order to insure specific advantages which cannot otherwise be obtained.

Before entering upon a series of illustrations of successful crossing of cattle for different objects we must observe that there is a direct pecuniary advantage in judiciously cross-breeding, and that increased size, a disposition to fatten, and early maturity are thereby induced. Whilst this may be the result for the most part by the very fact of crossing, yet it is principally due to the superior influence of the male over the size and external appearance of the offspring, so that it is desirable for the purpose of the butcher that the male should be of a larger frame than the female, and should excel in those peculiarities we are desirous of reproducing. We must, however, repeat it as an exceptional truth, that though as a rule the male parent influences mostly the size and external form, and the female parent the constitution, general health, and vital powers, including the milking capacity, yet the opposite result will occasionally occur.

Having been for many years engaged in the breeding of cattle of various descriptions for various purposes, as well as in the purchase of a large number for fattening purposes, we trust that some of our observations and remarks may be of use to some of those engaged in cattle breeding and feeding, and our experience has led us to observe both what will pay the breeder and be most sought for by the purchaser who intends to fatten. We have generally found that a preference has been given to animals which are cross-bred, and it is our intention to illustrate this by practical results.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—We are still employing the horses on the fallows for roots, pushing forward the work on the land intended for Swedes. These have been drilled for some few days in the northern and north-midland districts; yet it is customary in the southern and south-eastern counties to defer the sowing of Swedish Turnips until the first week in June, from the 8th to the 12th of that month being considered about the best time, except in case of roots required for early cattle feeding, in which case we find it a good plan to grow them in admixture with the Mangold crop, so that they may each be raised and stored away at the same time, or the Swedes used for feeding the cattle in the boxes or dairy cows in the stalls in case of a milk-selling dairy, and by growing them amongst the Mangold crop they become ripe and fit for use at the earliest period. In growing the Swedes by themselves for the main crop, if the land is likely to require much interculture in consequence of couch or weeds, we drill them at 2 feet apart on the flat, but on the stretch or ridge at 27 inches. In the event, however, of the land being clean, and there being only the ordinary infant weeds to be destroyed, we drill them at 22 inches between the rows. This has been found the best distance for yielding a full crop, for we have known it tested by the competition for prizes in a farmers' club for many years. After the catch crops, such as Rye, Trifolium, &c., are cleared off, whether by sheep-feeding or mowing for use as green fodder, the sooner the land, if intended for Turnips, Rape, or Kale, is ploughed and sown the better; but to be the more sure of a good seed bed the quicker the land is worked after ploughing the better the results will be—in fact, the work should if possible be done simultaneously, so that all the land ploughed each day should be reduced to a fine surface and seeded before the day's

work is finished. This plan will not only insure the retention of moisture in dry weather, but also will place the land in the best state to receive rain. At the time of ploughing after green crops removed, when it is done as fast as the crop is cleared, the land will always work more freely than when allowed to remain and become sun-baked. Strictly speaking, in the majority of seasons the root crops grown after green crops depend entirely for their successful growth upon the manner of tilling and sowing, as above stated.

*Hand Labour* will now be required in various ways, for the mowing season is near, and everything in connection with the haying period—such as implements and machinery—should be looked out and prepared for work after being thoroughly examined and repaired if necessary, in order that nothing may interfere with the work at the busy period. Cutting the grass early is of great importance as to the feeding value of hay, although it depends of course upon the making as well as the weather during the hay harvest. The advantages of cutting grass for hay whilst young and growing are very great, particularly hay for feeding sheep and lambs. We hold that by early cutting 1 cwt. of hay often contains as much nutritious matter as 1½ cwt. of hay when the grass remains to become old before mowing. This is a matter of great importance, because, as small animals can only eat a limited quantity, it should contain the greatest possible amount of nutrition. As showing that the system of making hay is of much consequence we will refer to an instance which we find in our memorandum book relating to the hay season of 1862. Our earliest crop of Trefoil, Clover, and Italian Ryegrass in that year was cut for hay on the 19th of May, and carted to the rick in first-rate condition on the 26th. Although the weather was difficult the first few days it proved fine from the 24th to the 26th; we were therefore enabled to get up the hay within six days after cutting. This could not have been done except by tedding and constant moving, as rain came on the 27th; and herein lies the advantage of the hay-making machine. Many farmers used to object to their use in the making of field hay, saying that too much of the Clover leaf was lost by the process, and it was considered best to allow the hay to remain in swathe, being turned over occasionally until dry and fit for stacking. This, however, is bad policy in our changeable climate, because it takes several days longer in making and adds greatly to the risk of damage by rain. We therefore advocate that the plan of making pasture hay should be applied to that of field hay also; for although hand labour sufficient could not be obtained, yet by the aid of tedding machines and horse rakes any amount of work can be done in a short time. We consider the hay is better made, with less risk of weather, with less loss of the Clover leaf; for being constantly moved it dries more regularly, the leaf not becoming so brittle and crisp as when allowed to remain in swathe and long exposure to the sun.

*Live Stock.*—Fodder crops have been very deficient this year, and this, together with the late growth of the field grasses, has caused and will continue to make green food scarce for both sheep and cattle. Much more cake and other feeding stuffs will therefore be required; but we must caution the home farmer in the management of stock, as we do not consider the manure arising from cake-feeding to be so valuable in the summer as when fed in winter months. Hedge and border grass should be continued for feeding young stock in the boxes, or dairy cows in the stalls if their produce is sold as milk, or in case of suckling calves for veal. In those cases where the Mangold crop is exhausted we cut up Clover or Italian Ryegrass for horses and also for cattle in the boxes. If the first cutting should be rather light there is some advantage by the second being likely to prove better, and the fodder supply being more regularly kept up. The breeding sows in the yards never do better than when fed on green fodder with a little Maize or Peas given in the troughs twice daily.

#### VARIETIES.

*BRITISH BEE-KEEPERS' ASSOCIATION.*—The Association will hold their seventh great Exhibition of bees and their produce, hives, and bee furniture, and honey fair, at the Royal Horticultural Society's Gardens, South Kensington, in connection with the Society's Flower Show, on Tuesday, Wednesday, Thursday, Friday, Saturday, July 26th, 27th, 28th, 29th, 30th, and Monday, August 1st, 1881, when prizes will be offered for stocks of Ligurian, Cyprian, or any other foreign bees; for hives and supers of various kinds, honey, and comb foundation. Classes are provided for cottagers, and foreign and colonial exhibitors. A counter will be appropriated to the exhibition and sale of honey in the comb and in glass jars, beeswax, and small apiarian appliances, and in this department goods may be purchased and delivered at all times during the Show. There will also be a driving competition, the prizes being awarded to the competitors who shall in the neatest, quickest, and most complete manner drive out the bees from a straw skep, capture and exhibit the queen. The system of open driving will be adopted; the receiving hive to be inclined at such an angle as shall permit the passage of the bees to be viewed by the spectators. Exhibitors must remit

the entrance fees with their entry forms properly filled up, in time to reach the Assistant Secretary (Mr. J. Huckle, King's Langley) on or before Saturday, July 16th.

— **BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION.**—The visit of the Bath and West of England Society and Southern Counties Association to Tunbridge Wells in the first week in June will be the fourth which the Society has made to the south-east of England. In the department of live stock the entries amount in the aggregate to 767, a number which is, with two exceptions, the largest ever reached by the Society. As might have been expected, the classes for Sussex cattle and Southdown and Kent sheep will form the great feature of the Show, while the collection of Jerseys will be one which both for extent and quality has been seldom surpassed. In the poultry department the "single-bird system" has been strictly reverted to. The total number of entries is 519, and includes specimens from nearly all the leading exhibitors, some of whom, however, have been prevented by the concurrence of one or two other large shows in the same week from entering so largely as usual. A novel and interesting department has been added this year to the Exhibition. A working dairy for the purpose of exhibiting the recent improvements in the treatment of milk and cream for the manufacture of butter, the process of butter-making, its curing and packing for transit, and the treatment of milk for travelling, will be in constant operation, and arrangements have been made to erect a stand, commanding a full view, for the convenience of those who wish to study the processes. Another new feature of the Show will be an exhibition of bees and bee appliances in a tent designed for the purpose, and the delivery of lectures at frequent intervals, with practical illustrations of the most approved methods of bee management and manipulation. The horticultural department will also maintain its attractiveness, and will include many choice specimens from the gardens and greenhouses of floriculturists of Kent and Sussex. Silver cups are provided for Orchids, and are expected to incite good competition.

— **THE ROYAL AGRICULTURAL SOCIETY.**—A general meeting of members was held last Monday at the Society's rooms in Hanover Square, Mr. W. Wells, President, occupying the chair. Mr. H. M. Jenkins, the Secretary, read the report of the Council, which showed a total membership of 7979, being a decrease of 103 since December. On the motion of the Earl of Feversham, seconded by Lord Rendlesham, Mr. John Dent of Ribston Hall, Wetherby, was elected President for the ensuing year.

— **THE BIRMINGHAM DAIRY SHOW.**—The entries in all departments closed on Saturday last, and it will be seen from the following returns that there will be a very large and interesting Exhibition—Cattle, 122; Goats, 22; cheese, butter, and cream, 352; bees, hives, and honey, 20; poultry and eggs, 615; collections of dairy and poultry appliances, 57; wool and other farm produce, 13. The poultry will be such as is considered best adapted for the farmyard. The supply of home-grown poultry and eggs for sale is by no means equal to our requirements or capabilities of production, and it is thought much good may be done if farmers' wives and daughters can be induced to devote more attention to the subject, which would be to their own advantage and to that of the populations of our towns by increasing the supply of eggs and poultry. Arrangements are in progress for the delivery, on some of the Show days, of short popular lectures on butter and cheese-making, poultry-keeping, &c., which it is hoped will be of much practical value.

— **SALE OF SHORTHORNS.**—The bulk of Mr. D. McIntosh's famous herd of Shorthorns at Havering Park, Essex, were sold last Thursday. Five bulls realised 543 guineas, the highest price for one animal being 310 guineas. Thirty-four cows and heifers realised the substantial sum of 1503 guineas. Two animals were bought for the Queen, seven to go to Belgium, and one, at 100 guineas, to go to America.

— **THE ROT IN SHEEP.**—The reports of the Commissioners appointed by the Royal Agricultural Society of England to investigate the disease known as liver rot, which has entailed such serious losses upon the agricultural community, have just been issued. In

1879 it is estimated that in England and Wales three million of sheep died or were sacrificed from rot, and that equally great losses occurred in 1880, and still continue. With regard to preventive measures, the Commissioners advise several methods for the capture and destruction of the fluke ova. Foremost amongst preventives is the removal from the land of superfluous wet, and towards this end it is stated that draining and ditching in many districts are being prosecuted with unusual energy. The protective effect of penning sheep on dry land at night time is also recommended. Again, concentrated dry food given systematically limits in a very striking manner the disastrous effects of flukes. Further, the regular use of common salt is well entitled to rank as a preventive of rot.

## POULTRY AND PIGEONS

### THE HATCHING SEASON.

AT page 410 you say you will be glad to hear from your readers respecting this matter, and we beg to send you a few notes on the subject. Here and hereabouts hatching has been about on a par with last season, and it was not considered very good. The best of all our eggs to hatch have been the Scotch Greys, then Dorkings, Sultans, and Buff Cochins. The latter have been very bad. Indeed, although we set many dozens of eggs of the Cochins we are ashamed to tell our increase, but of the Greys we are proud. Nearly every egg of these hatched, and we never had a greater per cent. of the right-coloured ones amongst them. Did we speak of Scotch Greys alone we would have no hesitation in saying that our hatching season had been a most successful one, but including all kinds it has only been half so, as our chicks only number about half the quantity of eggs set.
